Between 1981 and 1985, Federal investment in basic research will have increased by almost 30 percent in real terms. And we will carry forward that strong commitment into the future. We will also continue our support of tax credits for industrial R&D expenses, and we'll strive to lessen concerns that cooperative R&D between companies may violate antitrust statutes.

With the power of economic growth and the courage and determination of a free people, we can keep our number-one challenge in space—to develop a permanently manned space station, and do it within a decade. From that space station, we can carry out the kind of work in medicines and crystals I mentioned a moment ago; we can conduct new research, explore the distant planets, and, at the same time, unlock the vast potential for commerce in space by easing tax laws and regulations which discriminate against commercial ventures. And we'll be doing all these things for the sake of a more peaceful and prosperous world.

America has always been greatest when we dared to be great. We will be leaders in space, because the American people would rather reach for the stars than reach for excuses why we shouldn't. And as American technology transforms the great black night of space into a bright new world of opportunities, we can use that knowledge to create a new American opportunity society here at home. We can ensure every person

has not only an equal chance but a much greater chance to pursue the American dream.

To do this, we must maintain and increase our older industries' ability to compete in the world, stimulate creation of sunrise industries, and meet the challenge of ensuring American leadership and prosperity into the 21st century. Call me an optimist, but I'm convinced that if we do accept this challenge, if we maximize incentives, invest fully in the new technologies, and strive for the great breakthroughs in productivity, then, yes, we can outproduce, outcompete, and outsell the pants off anybody, anywhere in the world.

We can build an America that offers productive, secure job opportunities for all our fellow citizens, from assemblyline workers to research scientists in new industries such as biotechnology, robotics, and information processing.

We can meet our goal of assuring adequate supplies of affordable energy so that never again will the American people be held hostage by a foreign cartel.

We can apply new agricultural technologies to preserve our soil and environment, and dramatically enhance productivity through improvements in crop yields and resistance to disease and harsh environments. We can enhance our world leadership in agricultural production and in nutritional assistance to millions who look to America for hope and for help.

If we're to keep our economy healthy and strong, we need to stay healthy and strong ourselves. Our success will depend on each person's willingness to adopt healthy habits, our collective ability to improve an already effective health care system, and our continued research and pioneer work in the kinds of medical technologies you're developing right here. Before this decade is out, our administration is committed to reducing significantly the death rate for all age groups and to ensuring older Americans can live healthier, longer, and more productive lives. We can, and we must.

The dream of America is much more than who we are or what we do. It is, above all, what we will be. We must always be the new world; the world of discovery, the world that reveres the great truths of its past, but that looks forward with unending faith to the promise of the future. In my heart, I know we have that faith. The dream lives on. America will remain future's child, the golden hope for all mankind.

Thank you for welcoming me today. And thank you for all you do, and thank you for your courage to dream great dreams. God bless you all.

Mr. Beggs. Mr. President, if we may offer and present to you a small token of our appreciation for your coming here today. As you know, on the last shuttle mission, we went up and repaired a satellite. And that satellite—the Solar Maximum Mission Satellite—was developed here at Goddard, and indeed, the repairs were designed and developed here at Goddard. And they were installed with cooperation with the Houston Mission Control and the Houston astronauts, of course. It was a very successful mission, and we now have another very valuable scientific satellite working again for several years.

This model is a glass-blown model of that, showing the astronaut on his way out. And we hope that it will remind you many times, both of the visit to Goddard, as well as the strong support that you have given to this program and which we very much appreciate. And the encouragement which you continue to offer—we thank you for that very much.

Since the model is fragile, we'll deliver it to the Oval Office.

The President. Thank you very much. Thank you—thank you very much.

Mr. Beggs. What do you do up there without a horse? [*Laughter*]

The President. Thank you all very much. And now, as a little girl told me in a letter a few years ago—I'll get back to the office and go to work. [*Laughter*]

Thank you.

Note: The President spoke at 11:31 a.m. in the Center's Building 10. Prior to his remarks, he was given a tour of displays of space program work by James M. Beggs, Administrator of the National Aeronautics and Space Administration, and Noel Hinners, Director of the Goddard Space Flight Center.

SPACE WILL BE THE NEXT BIG CONSTRUCTION SITE

by GENE BYLINSKY

NASA plans to build an "antenna farm" that should transform communications here on earth. Satellites that tap the sun's energy could follow.

Man is a builder, ready to trek to the remotest corners of the earth for the profit and adventure of construction on a gigantic scale. Now, when the bold enterprises of corporations like Fluor, described in the preceding article, might be thought to have conquered the last frontiers, a new one is beckoning. For sheer drama, it may eclipse all the rest. If NASA has its way, the space near earth will soon begin to sprout all sorts of dreamlike structures, some of which are shown on the opposite page. Parasol-like antennae, some 100 feet across, will pop open in orbit to service an ever-expanding communications system back on earth—a system that will include pocket telephones not much bigger than Dick Tracy's wristwatch. Robot craft called "space spiders" will weave airy, fabulous structures out of materials little thicker than aluminum foil. Space-suited workers will be busy up there, too. In the near weightlessness of space even the scrawniest among them will be able to push around a structure that would weigh as much as a Mack truck on earth. Because these buildings will float in space, man will have the freedom to extend them in all directions at once—the dream of a small boy with an erector set come true.

This grand space show, duly publicized and televised by the space agency for the benefit of fascinated earthlings, will culminate at the turn of the century, or so NASA hopes, in the biggest space structures of them all: solar-power satellites. Each would be nearly as big as Manhattan, a startling twelve miles long and about three miles across. Shining like man-made stars at night, these giant platforms would beam energy to earth round the clock.

The first question that obviously comes to mind is: who needs these structures and who is going to pay for all the cosmic exhilaration? A single solar-power satellite, for instance, will cost somewhere between $2 billion and $20 billion, depending on whose estimate you believe, and the U.S. would have to have about 100 of them to supply 30 percent of its electric-power needs. The answer is that NASA's program is a mixture of the practical and the imaginatively farfetched. Some of the projects can be expected to pay their own way almost from the start, while others are too speculative for any meaningful cost-benefit analysis.

By 1983, NASA may be building the first simple structures in space with the aid of a beam-extruder to be carried aloft in the Shuttle's cargo bay. Solar panels will provide auxiliary power. The antenna farm at upper left is thought to be a viable commercial proposition, but debate still rages about the feasibility of solar-power satellites (upper right). As big as Manhattan Island, each of them would cost billions to build.

The practical, near-term projects will be in communications. Satellites that relay signals between points on earth are already a big and worthwhile business, and the first effect of the Space Shuttle will be to cut launching costs by more than half—from $20 million to $9 million. The cargo bay of the Shuttle will house a mechanical arm that can toss satellites out like basketballs—or reach out and retrieve them when they need repairs. As the communications traffic increases, the satellites will inevitably get larger and more powerful. The Air Force is already designing a dish antenna for radar that will collapse into a trim package for transport aboard the Shuttle and then pop open after it is launched.

The most useful space antennae are those in what is called geosynchronous orbit. This orbit, 22,500 miles up, keeps them above a given spot on earth and so always in a good position to receive and transmit signals. Many of the satellites launched in near-earth orbit by the Shuttle will be

Research associate: Alicia Hills Moore

equipped with rockets to take them on up to their stations. Later on, however, as communications needs continue to grow, it will be more efficient to build a great battery of antennae—an antenna "farm," as NASA calls it—in the near-earth orbit to which the Shuttle will be confined. The metal skeleton, perhaps 700 feet long, would house as many as thirty large dish antennae. Once completed, it could be towed or propelled up to geosynchronous orbit.

According to a study by Rockwell International, such an antenna farm could simultaneously satisfy many different communications needs. It could easily handle the rapidly growing volume of electronic mail, most of it generated by business. It could accommodate up to five nationwide television channels, though the viewers back on earth would have to buy a one-meter dish antenna at a cost of about $100. Because this transmitter in space would be much more powerful than those now in place, the receiving stations on earth could be simpler—as simple, in fact, as those pocket phones. An antenna farm could service as many as 45,000 private channels, which could handle calls from millions of pocket telephones. Rockwell estimates that the calls, which could also be made to and from conventional telephones, would cost only about 20 cents each. "We feel very confident about the technology we've designed," says C. L. Gould, an engineer who led the Rockwell study. "I think a company like ours could take a fixed-price contract to build the pocket telephone right now."

Rockwell also thinks that inexpensive satellite communication will be of great benefit to the underdeveloped world. Paramedics in remote villages would be able to get a diagnosis of difficult cases by pocket telephone and young people could be taught new skills by television.

It is in building the antenna farms that construction in space will really begin, probably around 1985. To get a jump on some of the problems, however, Grumman has already designed a beam extruder, a later model of which will be carried aboard the Shuttle (see the photograph on next page). It can turn out a triangular, interconnected skeleton of thin aluminum at a speed of five feet a minute. At that rate, the beam builder could cough up a mile-long structure in less than a day. There will be cherry-picker cranes equipped with their own maneuvering rockets, as well as more mundane space tools such as cable cutters, adjustable wrenches, pliers, and scissors. "You could go to any construction site and see equipment that might be schematically the same as we might use in space," says Allen J. Louviere, chief of the spacecraft-design division of NASA's Houston center. "You'd have to have workers, materials, trucks, an eleva-

tor, a crane. We've got to have all those, too, but they may look different and operate somewhat differently because of the unique conditions in space."

The main difference from conditions on earth—the virtual absence of gravity—is more advantage than problem. Structures won't have to bear the stresses they do on earth and will serve merely as a positioning framework for the mechanisms attached to them. "You don't have to worry about high winds, or a snowfall that might crush the roof," adds Richard L. Kline, deputy director of advanced space programs at Grumman. "The structure won't rust or corrode, either, the way my car does."

The biggest stress these structures will have to bear will be the thrust of the rockets used to move them up to geosynchronous orbit. Once they are 22,500 miles up and out from behind the earth's shadow, they will be bathed in continuous sunlight except for a few minutes of eclipse during the days of the spring and fall equinoxes. But the temperature change during an eclipse will be dramatic—as much as 700 degrees—and large expanses of thin metal would tend to curl around the edges. Other materials, such as a composite of graphite and epoxy, will hold up fine.

Weightlessness is not quite so congenial to humans. The orbital assembly men will have to have a grip on something solid. Otherwise, says Louviere of NASA, "if the thing you're trying to work on is bigger than you are, you may find that it's turning you, rather than you turning it." Spacesuited workers are rather clumsy, too, and tire easily, so a lot of mechanical aids will be used. A shirt-sleeved astronaut sitting in a flying robot with mechanical arms will be able to get a lot more work done. The astroworkers will have to be neat. Any debris will hang around their work sites to haunt them. If a workman drops a tool up there, it will not fall, of course, but slowly drift away.

As assembly moves farther out to the geosynchronous orbit where the solar-power satellites are supposed to be built, new hazards will loom. To shield themselves from periodic bursts of potentially fatal radiation from the sun, the astronauts would mostly work inside robot craft or control centers, directing mechanical arms and other automatic equipment. One of the first things Rockwell would like to see them build out there is the "Lunetta," a mirror perhaps a thousand feet in diameter. Clusters of these Lunettas would flash back as much sunlight as 200 to 300 moons, illuminating the streets of a city at night and saving energy on the ground. Rockwell thinks Lunettas could also be used to beam light to remote construction and exploration sites, such as Alaska's North Slope, and to augment the sunlight on croplands.

Solar-power satellites will be a grand climax to the space show—if they are ever built. Unlike earth-based solar collectors, these satellites would face no vagaries of weather or day-night cycles, and thus would be exposed to ten times the amount of sunlight available on earth. The thirty-six square miles of solar cells would feed ten megawatts of electricity into the antenna portion of the satellite, where it would be transformed into microwaves and beamed back to earth. Receiving antennae on the ground would turn the beam back into electricity, and put it into the power grid.

What would be an impressive construction job on earth becomes a mind-boggling one in space. NASA estimates that 550 workmen would be needed to build a solar satellite, and some space planners are already worrying about how to keep that many people healthy and happy in space. Each satellite would require 100,000 tons of materials, much of it exotic composites that now cost as much as $50 a pound.

continued

Ferrying up the people, equipment, and supplies would take ten flights a day by the Shuttle or its successor.

The job looks so formidable that some space boosters have seriously suggested using the moon rather than the earth as the main source of raw materials. Because the moon's gravitational pull is weaker than earth's, much less power would be needed to lift off large payloads. In this scheme, the moon's abundant and high-grade ores would be propelled for processing to space colonies in very high orbit or at the so-called Lagrange libration points, 250,000 miles from earth, where large structures would remain stationary because the gravitational pulls of the earth, the moon, and the sun are equalized there. The Rockwell report gave this plan rather cool treatment, but NASA is still studying it. Sunsat, an aerospace lobby, and L-5 clubs around the country (named for the fifth libration point) are keeping hope alive.

Apart from the cost of solar-power satellites, there are unresolved questions about just how safe those microwave beams would be for life here on earth. They would be carefully directed into the huge receiving antennae, and would in effect harmlessly defocus if a beam got "unlocked" from its antenna. But nearby areas would pick up a low-level dose, and nobody knows yet what long-term effect this would have on animals, plants, and man.

Advocates of the solar-power satellites point out that the beams would be only about one-fourth as intense as sunlight. Unlike sunlight, though, microwave radiation can be highly penetrating even at low intensity. Songbirds, which happen to be about the same size as the wavelength of the radiation, might almost resonate if caught in the beam. They would certainly absorb more microwave heat than humans.

"We need to know whether birds, bats, bees, and other species flying over the receiving antenna will be killed by the microwave beam," says Richard D. Phillips of Batelle Pacific Northwest Laboratories, who managed a study on the potential biological effects of the beam for the Department of Energy. "If the flying biota are killed, it may mean that the solar-power satellite concept, as now designed, is not feasible." Even if the beams are less dangerous than feared, says Phillips, the receiving antennae may have to be situated in remote, sparsely populated areas.

There are also unanswered questions about the beam's possible effect on the atmosphere—in terms of both heating it up and disrupting communications on earth. But the solar-power satellite holds such an enticing promise of unlimited energy that it at least deserves further study. Peter E. Glaser, a vice president at Arthur D. Little, Inc., who first proposed the idea ten years ago, suggests that if the U.S. finds the costs too much to bear, it might go into partnership with other countries. Glaser himself thinks that it would be irresponsible to commit the U.S. to the construction of solar-power satellites on the basis of current knowledge, but he also thinks that we should be spending at least as much on feasibility studies as we are on windmill research (currently $60 million a year). Other scientists would like to see us push ahead more rapidly, and one of them, Arthur Kantrowitz, who retired recently as chairman of Avco Everett Research Laboratory, has put his feelings in verse:

Arise, creators of worlds yet unimagined,
You have nothing to lose but your limits.

The decision rests ultimately with Congress, but whatever the exact level of funding, power from space, like power from fusion, isn't likely to arrive until the next century. Before the first crews take off to begin building the first commercial-scale satellite, space construction will have yielded major returns in transforming communications here on earth. ■

Coming down to earth

Industry in space is a mirage of abundance.

Daniel Deudney, WORLDWATCH INSTITUTE.

by Daniel Deudney

No one looking at space a quarter century ago foresaw all ways in which space systems have altered human life, and no one today predicting space activities over the next 50 to 100 years is likely to predict all the uses to which satellites will be put. Yet enough is known about the potential of space and the needs of earth that some ideas—large-scale space colonies, solar power satellites and asteroid mining—can be eliminated as practical and desirable goals. A modest industry producing certain high-quality products is possible within this time horizon, but is unlikely to surpass the economic contribution of communications satellites. The longer-term prospects for human ventures in space are, of course, not knowable. But large-scale space industrialization is not a viable solution to the pressing population, energy or resource problems of the earth.

The success of the satellite-communications industry has spawned a great deal of speculation about the possibility of building industries in space. Experiments aboard the U.S. Skylab in 1974 revealed that the weightless, airless conditions of space enabled the production of certain goods that are impossible to manufacture on earth. Without gravity, crystals form much more regularly, permitting the creation of glasses and electrical devices that have vastly higher performance than any others. And the products can be formed without containers, eliminating impurities that are the major limit to the performance of certain optical and metallurgical products on earth.

The drug industry could be a major user of weightless space to achieve delicate separation of complex, nearly identical substances. A Johnson & Johnson subsidiary is working with the National Aeronautics and Space Administration (NASA) to conduct an extensive research program. Jesco von Puttakamer, a long-range planner at NASA, estimates that space manufacturing could lower the production cost of a drug that fights blood clots from its current $1,200 a dose to around $100, perhaps saving some of the 50,000 people who die of clots each year. Because cooling metals do not form convection currents in a vacuum, strong alloys can be made from metals that are grainy and crumble when combined on earth. Thus the German auto manufacturer BMW is reportedly interested in fashioning lead and aluminum alloy motor parts that would be highly heat resistant, self-lubricating and last for a half-million miles of use.

Expert opinion about the prospects for space manufacturing is sharply divided, reflecting the limited number of experiments that have been performed and the large uncertainties about the costs of setting up a commercially viable factory in space. The many experiments in materials processing scheduled for the shut-

---

*Daniel Deudney is a senior researcher with Worldwatch Institute, an international research organization funded by the United Nations and various private foundations. This excerpt is drawn from Worldwatch Paper 50—*Space: The High Frontier in Perspective.

tle-launched Spacelab in 1983 will answer some questions, while undoubtedly creating even more. Because the most critical factor in the economics of space processing will be the weight of the raw materials and the processing equipment, the first markets are likely to be for products with a high value-to-weight ratio, such as pharmaceuticals and electronic devices, followed by specialty glasses and alloys. A study for NASA by Microgravity Research Associates estimates that two or three $500-million space factories, weighing 15,000 kilograms and serviced every three months by the space shuttle, could meet half the growth in demand in semiconductors in the United States over the next decade.

If these visions of space manufacturing materialize, the products will be quite expensive, limiting their use to markets such as advanced weapons systems, scientific instruments and medical devices where performance, not price, is critical. However, the most probable payoff from space materials experiments is likely to be new knowledge of how materials interact that can be applied in terrestrial manufacturing. The principal financial supporters of Spacelab, the West Germans, look to these experiments to augment their knowledge of basic materials science rather than as precursors to industrial manufacturing in space.

Although space manufacturing may become a modest industry some day, large-scale space industrialization is an unworkable attempt to escape from the problems of earth. Much of the recent writing about humanity's future in space has been dominated by a group of outlandish proposals for industrializing space—solar power satellites, space colonies and asteroid mining—that aim to bypass the earth's resource limits by importing energy and materials from space or exporting people from the planet. At first glance these massive undertakings have a certain logic: the

earth is limited, space is infinite. Outer space does contain vastly more energy, space, and materials than earth. Yet this abundance cannot be brought to bear meaningfully on the earth's problems. Based as they are on misleading ideas about the nature of humanity's earthbound resource predicament, attempts to realize these fantasies are likely to exacerbate the problems of the earth during a period of unprecedented environmental stress. Rather than signs of hope in a time of troubles they are the most grandiose hallucinations of technological civilization.

The plans for the large-scale habitation and exploitation of space have evoked extensive public enthusiasm, which reflects at least a growing realization that the present course of growth on earth cannot continue indefinitely. Long a staple of science fiction writers, space colonies were first seriously proposed in the early Seventies by Gerard O'Neill, a Princeton University physicist. In *The High Frontier: Human Colonies in Space*, O'Neill detailed plans to build colonies with at first 10,000 inhabitants, and later a million. Manufactured out of materials from the earth, and then the moon, the colonies would be completely self-sufficient by harnessing the sun for all sources of energy. Space colonization is specifically promoted as a solution to overcrowding and environmental degradation on the earth. By exporting even greater numbers of humans into these orbiting cities, the wildlife and wilderness qualities of the earth could be protected, he claimed, or perhaps even expanded.

Life there is envisioned as pastoral, pollution-free, pluralistic—sort of floating garden cities. "Artists' recreations" depict vast transparent domes with sunlight flowing in for plants and lighting. The reality of space habitation would be far bleaker for centuries to come. The radiation belts around the earth make these visions misleading to the point of fraud. Heavy thick metal shielding would be necessary to block the lethal quantities of cosmic and solar radiation. Life in space for the foreseeable future will be like that in a submarine, an offshore oil platform or an Antarctic mining camp—dangerous, cramped, isolated, and uneventful.

Large-scale space colonization is not now—and may never be—technologically feasible. Structures of the size envisioned are thousands of times larger than anything yet built in space. If the record of similar scale-ups on earth is any guide, there will be unforeseen and perhaps insurmountable problems. Ecologist Paul Ehrlich points out that scientists have no idea how to create large, stable ecosystems of the sort that would be needed to make space colonies self-sufficient. The key to such knowledge is, of course, much more study of the ecosystems on earth, many of which are becoming less diverse and less stable. It could be many decades before scientists know enough to understand, let alone recreate, ecosystems as complex as those now being degraded.

Nor are space colonies a meaningful response to the population and environmental problems of the earth. At a time when 800 million humans live in "absolute poverty" on earth, it makes little sense to think about building fabulously expensive habitats in space. Simply transporting the world's daily increase of about 200,000 people into space would consume the annual gross national product of the United States. And long before technology made space colonies feasible, the current rate of population growth would have caused the earth's life support systems to collapse. Human population growth is not an inevitable natural necessity requiring an ever more expensive technical response. Population stabilization is a difficult social challenge, but it is certainly less complex than the organizational and political skills needed for large-scale colonization of space. Even if feasible, the endless multiplication of human beings in these hive canisters is ultimately as pointless a vision as it is bleak.

> "Although space manufacturing may become a modest industry some day, large-scale space industrialization is an unworkable attempt to escape from the problems of earth."

The space resource venture given the most attention as having near-term relevance to humanity is the solar power satellite, or SUNSAT, envisioned first in 1968 by Dr. Peter Glazer. A solar power satellite system would consist of three parts: an orbiting array of photovoltaic cells to collect and turn sunlight into electricity, a microwave beamer to send the power through the earth's atmosphere, and fields of microwave antennae on earth to convert the beams back into usable electricity. Variant designs would use lasers in the place of microwaves, and mirrors in the place of photovoltaic cells. The system's principal appeal is its ability to collect virtually unlimited amounts of solar energy without obstruction from the atmosphere or the cycle of night and day and without polluting the earth's atmosphere with combustion by-products. During the Seventies, as energy costs rose and environmental constraints became increasingly visible, SUNSAT proponents, backed by large U.S. aerospace corporations, created considerable public and government interests

in the idea. They claimed that mass production of photovoltaic cells and new rockets many times the size of those in use today would make this scientifically feasible venture into one that was also technologically and economically viable.

The construction of SUNSAT would be an undertaking of unprecedented size and cost. A 1980 NASA and U.S. Department of Energy study estimated that 60 satellites, each as big as Manhattan Island, would be needed to produce 300 gigawatts of electricity, which is roughly the current U.S. usage. The cost estimates ranged from an optimistic $1.5 trillion to a more probable $3 trillion. If two SUNSATs were built each year, one heavy-lift rocket—seven times the size of the largest rocket ever built—would have to be launched each day for 30 years to build and service them.

After an initial burst of favorable press by space and energy groups, several in-depth studies of SUNSAT by panels of independent scientists and analysts concluded that the concept faced technical, economic, environmental and political hurdles that are probably insurmountable. The U.S. Office of Technology Assessment concluded that SUNSATs involved as many environmental risks as large-scale terrestrial energy systems such as coal and nuclear power—and more technological uncertainties. A 1981 study by the U.S. National Academy of Sciences went a step further, concluding that obstacles to solar power satellites were so great that no funds should be spent for its development for at least the next decade, a remarkable recom-

mendation for a group usually highly sympathetic to research.

The barriers to an economical SUNSAT are technological rather than scientific. At each step in its construction, technological barriers would have to be broken and costs would have to fall rapidly. Photovoltaic cells are now being made, for example, and there may soon be cheaper ones. But scientists do not know how to make cheap ones with the ability to withstand intense radiation and cosmic ray bombardment for decades. Similarly, many major advances and scale-ups in rocket design and the handling of materials are needed to build such large structures in space. One major uncertainty in the cost of SUNSAT is labor. Preliminary evidence suggests that workers could not stay in orbit at the construction site for more than a few days without absorbing unsafe levels of radiation. Unless the health of thousands of highly trained workers is to be sacrificed on this high-energy altar, work tours would have to be short, driving up training and transportation costs.

Even more troubling than these constraints are planetary-scale environmental risks. Beaming trillions of watts of microwaves through the atmosphere for extended periods of time is almost certain to alter the composition of gases in unpredictable ways. Launching millions of tons of material into orbit would also place large quantities of exhaust gases into the upper atmosphere, perhaps disrupting the thin bands of volatile gases, such as the ozone layers, that play important but poorly understood roles in regulating the habitability of the earth. An operational SUNSAT system big enough to make a difference in the terrestrial energy equation would be a shot-in-the dark experiment with the human race's one habitable environment—the earth's atmosphere.

The political and institutional barriers to SUNSAT are less quantifiable but no less intractable. These large satellites, powerful sources of electromagnetic radiation, would orbit in a relatively small band of near space that already carries a great deal of satellite traffic, so other uses of space would be constrained. At the minimum, international agreements would have to ensure that energy benefits reached those who would have to forgo other uses of these orbits. The operation of such a system would involve worldwide resource allocation regimes far beyond those now in existence. If these massive power systems ever fell into the hands of terrorists or politically ambitious generals, or fell back into the earth's atmosphere, the results could be disastrous.

One other mirage of abundance in space that has recently received attention is asteroids. A scheme to mine them to meet mineral needs on earth has also been proposed in some detail by former U.S. astronaut Brian O'Leary. These irregularly shaped rocks that orbit the sun, mainly between Mars and Jupiter, range in size from as small as a grain of sand to as big as the state of Texas. Although our direct knowledge of asteroids in space is limited, scientists have studied the composition of a few that have over the millennia collided with the earth. Many asteroids have nickel and iron contents several times as high as ores now mined and, unlike metallic ores on the earth, do not require energy-intensive smelting. Indeed, the world's largest and highest grade nickel deposit, in Sudbury, Ontario, is believed to be the remains of a giant asteroid that struck the planet over two billion years ago. Although there is probably enough metal in the asteroid belt to meet world needs for many centuries, getting the asteroids to the earth's surface would be costly and energy-intensive, and would risk an accidental collision and ecological disruption on a colossal scale. Long before it becomes feasible or economical to bring rare metals in from space, scientists should be able to turn the prodigiously abundant clay, silicon, aluminum, hydrocarbons and iron in the earth's crust into plastics, ceramics, specialty irons and glasses to meet global materials requirements. ■

FOR INDUSTRY IT'S ALMOST LIFT-OFF TIME

THE SHUTTLE'S SUCCESS AND CONGRESSIONAL SUPPORT SWEEP ASIDE SKEPTICISM

Just a few years ago, the idea of manufacturing products in floating factories orbiting 300 mi. above the earth seemed like so much pie in the sky. With the U.S. manned space program at a low ebb and the shuttle program plagued with delays, the efforts of the National Aeronautics & Space Administration to lure companies aloft were greeted with skepticism or with lukewarm interest at best.

But now industry is on the verge of embracing space. The shuttle is sailing from orbit to earth more easily than even its most ardent boosters predicted. And the Reagan Administration is encouraging NASA's plans to have a permanent space station in orbit as early as 1991. As a result, companies from Aluminum Co. of America to Western Electric Co. are beginning to view the heavens with an eye to their scientific and commercial possibilities. In fact, a recent NASA-funded survey turned up 84 companies interested in doing some 244 experimental and commercial projects in orbit.

The space agency has long nurtured a desire for a manned space station as a logical extension of the shuttle program. That project has been on the back burner, however, as NASA suffered through the years of budget cutbacks that followed the Apollo moon landing and labored under criticism of budget overruns on the shuttle.

SURPRISE MONEY. Now the mood has changed. Congressional support for a manned space station is so strong that both houses are forcing money on NASA. When the agency recently asked for $6 million for space station design studies, the House voted to add $10 million and the Senate $5 million. Says Representative Don Fuqua (D-Fla.), chairman of the House Committee on Science & Technology: "I had to restrain the subcommittee dealing with space."

With the shuttle ready to truck large components into space, NASA is raring to go. Building a permanent space station is "a piece of cake, compared with building the shuttle," says Robert F. Freitag, deputy director of the agency's Space Station Task Force. "There is nothing that we need to invent."

Preliminary plans call for a structure more than 200 ft. long and 100 ft. wide that will look like an odd collection of shiny cans flanked by huge arrays of solar cells. It will contain living quarters for four to six astronauts. Three or four pods will house laboratories. Space shuttles will dock periodically, bringing supplies, new crew members, and even entire room-size modules that can be "snapped" onto the station.

NASA figures it can put up such a space station at bargain-basement prices: a total cost of $7 billion to $10 billion. By comparison, it cost more than $16 billion to get the shuttle off the

ground, and the Apollo moon program cost $25 billion. NASA expects to have its first design for a manned space station in final form by mid-July. By September, 1984, detailed plans should be ready. NASA wants to award construction contracts by early 1986.

In all, NASA will spend about $40 million in the current fiscal year to develop a space station and promote its use. And the agency intends to ask the Administration to step up the level of spending when it considers fiscal 1985 budget requests in September. "I would like to see something in the order of $100 million in 1985," says NASA Administrator James M. Beggs.

HARD SELL. To get the money it needs, NASA has pulled out all the stops in an effort to muster support for the manned space station. It has launched a raft of feasibility studies and is hitting industry with a hard-sell campaign to persuade companies to gear up for space. NASA expects considerable help from a special Senior Interagency Group—including the Secretaries of State, Defense, and Commerce, the chairman of the Joint Chiefs of Staff, and other officials—that President Reagan has appointed to advise him on a space station program.

But the critical step for NASA will be getting industry on board. Agency officials believe that once industry has explored the merits of space, continued industrial involvement will follow. "We are going about our planning in a practical way," says Beggs. "Rather than design a space station and then try to figure out specific uses for it, we are taking the opposite tack: nailing down the needs of the users. We feel that the station architecture and design elements will evolve naturally from those needs."

To get its first input on just what the users may require, NASA last fall awarded eight aerospace companies contracts of $750,000 each to pinpoint just what U.S. industry would consider doing in space. Their report turned up companies interested in projects ranging from assembling giant communications satellites to developing new ways of processing materials and making drugs.

In addition, NASA is using consultants Booz, Allen & Hamilton Inc. and Coopers & Lybrand to proselytize 50 companies that are most likely to launch space ventures and collect information on their needs. Targeted are such companies as Du Pont, Eli Lilly, Mobil Oil, W. R. Grace, International Business Machines, and Hewlett-Packard. "Companies must be led into thinking space," says John J. Egan, who manages business planning at Coopers & Lybrand.

AT WORK IN SPACE

A modular space station (1) floats serenely 300 mi. above the earth. The 300-ft.-long structure with its wing-like solar cells and huge communications antenna will house scientists and work crews. Surrounding the station are unmanned platforms (2) for manufacturing or long-term experiments. Supplies and new crew members will be ferried up from earth by the shuttle (3). Astronauts will ride to the platforms in solar-powered tenders (4.)

Some critics charge that NASA has ulterior motives in its fervent efforts to involve industry. The agency's future depends on launching a long-lasting program that will have broad support. "They're looking for anybody who will support a space station," says one aerospace scientist.

MORE SATELLITES. So far, the communications industry has been NASA's biggest industrial customer. The space shuttle launched two communications satellites on its fifth flight last November, one for Satellite Business Systems and the other for Canada. More than 100 such satellites are booked for launch by the shuttle in the next seven years. The current industry push to start direct-broadcast satellite transmissions to homes will undoubtedly add even more communications satellites to the shuttle schedule.

But in the long run, NASA officials expect other commercial space ventures to dwarf the satellite launch service it now provides to industry. The agency has put together a smorgasbord of inducements to get cautious companies to take the first steps toward broader uses of space. On May 27, NASA announced that it will fly a shuttle mission in 1986 filled only with industrial experiments. Not only will the flight be free but NASA is also offering to kick in $100,000 toward the cost of approved experiments. "We call it our 10¢-off coupon," says John W. Cole, chairman of the commercial group

within NASA's Space Station Task Force.

The agency is also doing a brisk business with a "Getaway Special" program, which offers a budget research jaunt on the shuttle. For $10,000, NASA will launch a 5-cu.-ft. "garbage can" stuffed with experimental gear. And scientists can keep their work confidential. "Companies like it because we don't have to know everything that's going on in that can," says William K. Vardaman, NASA's manager of commercial applications.

The most ambitious program to date, however, allows companies to form exclusive joint ventures with NASA. Under the agreement, NASA takes responsibility for part of a company's project. NASA scientists may, for example, integrate experimental apparatus into the shuttle. Shuttle flights are free for as long as the work is in the research and development phase. When production begins, however, the free ride ends, and the company will have to pay for the flight, which can cost as much as $5 million for four to five working days on the shuttle.

PROMISING IN DEPTH. Nonetheless, the agency's efforts are attracting increasingly serious interest from industry. McDonnell Douglas Corp. and Ortho Pharmaceutical Corp. became NASA's first industrial partners more than three years ago. NASA expects more partners by the end of the summer.

Moreover, the McDonnell Douglas project, which uses a separation process called electrophoresis to manufacture drugs in space, is moving ahead at full speed. The companies first flew their apparatus on the shuttle in June, 1982, and four more flights are planned before the end of 1984. The experiments have shown that 700 times more biological proteins—such as hormones—can be gleaned from batches of cells in space than on earth. Based on those results, the company plans to launch a prototype manufacturing plant in 1985, with full-scale production starting on an orbiting platform in the late 1980s. "We could get into a positive cash-flow position within a few years after we start manufacturing," says James T. Rose, who heads the program.

One enterprising startup already has plans to base its entire business on space processing. Three-year-old Microgravity Research Associates (MRA) is the second company to form a joint R&D venture with NASA. The Coral Gables (Fla.) company hopes to produce semiconductor crystals in space. "It was becoming clear that the opportunities were coming to put these things together. The time was ripe for someone to get up there, and we decided to take a crack at it," says Richard L. Randolph, MRA's president and founder.

Several others are in the preliminary stages of setting up similar agreements. Fairchild Industries Inc. plans by 1986 to orbit small unmanned platforms that would stay permanently in space. Called Leasecraft, they would be rented to other companies for research and manufacturing. The platforms could be carried aloft and serviced by the shuttle. One company negotiating with Fairchild is McDonnell Douglas, which would use the platform for drug production.

Ball Aerospace Systems Div. of the Ball Corp. in Boulder, Colo., is negotiating with NASA to build a materials-processing lab to fit into the shuttle's cargo bay. Similarly, Teledyne Brown Engineering Co., of Huntsville, Ala., wants to build a general-purpose lab, also to be flown on the shuttle. "We could book customers now if we had the facility," says Lawrence R. Greenwood, deputy director of spacecraft systems at Ball.

COSTLY PAYOFF. The handful of companies with actual production plans for such facilities is in the vanguard. Space processing is expensive: Launch and recovery costs for apparatus and product exceed $5,000 per lb. At these freight costs, "you have to have a material that will sell for a very high figure per amount of weight" to make space processing worthwhile, says MRA's Randolph. So far, drugs and semiconductor materials are the only obvious candidates. Some advanced semiconductor materials such as gallium-arsenide can sell for as much as $50,000 per lb. And some pharmaceuticals can be worth up to $22 million per lb.

Many other companies are gearing up to use space as a lab. "The first thing space is offering us is an important opportunity to conduct research that we couldn't do on earth," says Paul E. Ritt, vice-president and director of research at GTE Laboratories Inc. in Waltham, Mass.

The lure of space to researchers and potential manufacturers is the near absence of gravity. By separating the effects of gravity from other forces such as viscosity and surface tension, scientists hope to be able to develop new or improved materials, including exotic crystals for advanced electronic devices, specialized alloys, and pharmaceuticals. "Any scientist would like to avail himself of the low-gravity environment," says David J. Larson, a staff scientist at Grumman Aerospace Research.

Manufacturers of advanced semiconductor crystals are among the most enthusiastic proponents of space research. Their goal is to use space to grow perfect versions of crystals such as gallium-arsenide that may replace silicon as the basis of the next generation of chips.

On earth the pull of gravity separates

components such as gallium and arsenic according to their densities and makes it hard to grow a uniform crystal. NASA's Vardaman compares the process to trying to make Jell-O with fruit in it—gravity pulls the fruit to the bottom. "In space you don't have that," he says, "so you can make a real good cup of Jell-O."

Other crystal defects are avoided in space because of the absence of convection caused by heating and cooling in the molten liquid from which crystals form. This stirring effect causes flaws in a crystal that in turn cause variations in the crystal's electronic properties. Such defects mean many finished semiconductor devices must be rejected.

Scientists at Grumman Aerospace Research are exploring the effects of gravity on the magnetic properties of crystals

Some 84 companies tell NASA they are interested in 244 experimental or commercial projects

used in detectors for the military. By applying the results of experiments done in space, the company has already improved some magnetic properties of earth-grown crystals by 50%. "The space material is the best we've ever produced," says Grumman's Larson.

Microgravity also makes it possible to process materials without having to hold them in containers. Molten metal, for example, becomes a spherical blob, and a tiny electric or magnetic field is enough to hold it in place. Johnson Matthey Inc. thinks this may provide a way to produce the iridium crucibles in which many semiconductor crystals are grown. Iridium is a temperamental metal with a melting point of 4,400°F. "It has a high chance of being contaminated while being melted, and if contaminated, it becomes brittle and difficult to work," says Laurence R. Thomas, Johnson Matthey's manager of technical services. **PURITY.** In space, contamination from contact with a container is eliminated, and the resulting iridium would be far purer than that produced on earth. One Johnson Matthey official estimates that high-purity iridium made in space would sell for $500 per oz. more than the material's present price of $1,000 per oz.

Many companies are investigating space research from the ground before committing themselves to large-scale efforts. "You can process candidate materials and weed some out before you go to the shuttle," says Michael B. Robinson, a staff scientist at NASA's Marshall Space Flight Center in Huntsville. Many are conducting experiments on rockets and high-altitude aircraft, where several seconds of weightlessness occur when the vehicle reaches the top of its trajectory. "This information provides direction and focus to our earthbound efforts," says Norman P. Lillybeck, manager of metal processing research at Deere & Co., which sent a furnace aloft to study carbon particles in cast iron.

Others are conducting experiments using a 340-ft.-tall "drop tower" at the Marshall facility. Du Pont used the tower to explore new ways of mixing materials to make catalysts. A furnace at the tower's top melts the material, which plummets earthward, solidifying in the 4.6 seconds of weightlessness of its fall.

In its effort to drum up interest from industry, NASA is getting some support from the Europeans and the Japanese, who are also eager to commercialize space. In Germany, for example, Messerschmitt-Bölkow-Blohm, as a private venture, has plans for free-flying platforms similar to Fairchild's Leasecraft. The company has already built a rudimentary free-flyer called SPAS that is due to be put into orbit by the next shuttle flight on June 18. The European Space Agency (ESA) is also planning a larger free-flier called EURECA, also to be built by MBB and launched by the shuttle. EURECA is scheduled for its first flight in April, 1987, and is to stay in orbit six months. **EUROPE AND JAPANESE.** Germany's Fried. Krupp has one of the most vigorous space programs under way. It is exploring the possibility of producing a magnetic alloy in space that would be virtually impossible to produce commercially in the earth's gravity. "This is definitely a candidate for eventual processing in space," says Jürgen Pötschke, who directs the program.

The National Space Development Agency of Japan is trying to push industry into more use of the U.S. shuttle. "We see improvements and innovations in the high-technology area if we can utilize the extraordinary conditions of space," explains Kazuo Matsumoto, director of the agency's space shuttle utilization department.

Although those efforts represent cooperation at this point, they may spell competition in the future. One German company official cautions that the Japanese may initially concentrate in specific fields and then move fast. Warns that official: "Europe has to watch out that it doesn't get run over from behind by the Japanese." Commenting on that observation, a NASA official who preferred anonymity added: "And the U.S. may get run over by both of them—using our own truck, the shuttle."

But if U.S. industry climbs on board the way NASA hopes, and if Congress backs the space platform program—as now appears likely—there seems to be little doubt that the U.S. will build the permanent presence in space that the shuttle promises. The shuttle, says Rose of McDonnell Douglas, "is a new transport system, and if you look back at the railroad and the airplane, you can see their effect on business and commerce. In several years the shuttle will seem like the original steam engine." And it is inevitable, he adds, that "space will be commercialized."

Why Drugs Will Be Made In SPACE

by Donald C. McLearn

Sally Ride gained international fame this year as the first American woman in space; but aboard space shuttle Challenger she also tested a drug-making machine of tomorrow—one that promises to produce enough rare biological products in space orbit to bring relief to millions of patients here on Earth.

Following up on this experiment, a pharmaceutical company, in this decade, may set up branch plants in space to produce products like interferon, beta cells, and other materials now only available in small quantities.

For years scientists have known that cures for a number of diseases might be possible using certain cells, enzymes, hormones or proteins. But, while most of these materials are obtainable on Earth, the processes used to produce them are so limited by gravity that there's only enough made to conduct research. In space, away from the confines of gravity, it's possible to obtain these materials in great quantities and with the purity needed to treat diseases.

The space-age manufacturing technique, called continuous flow electrophoresis, separates materials in solution by subjecting them to an electrical field. The McDonnell Douglas Corp. of St. Louis developed the device and is in partnership with Ortho Pharmaceutical Corp., a division of Johnson and Johnson, New Brunswick, N.J., on the first product to be made. The National Aeronautics and Space Administration is providing the transportation and space scientists to run tests.

The in-space drug experiment has been given the acronym EOS, for Electrophoresis Operations in Space. The project was conceived six years ago. Tests of the device, using NASA's

space shuttle, began during the fourth shuttle mission in June 1982. A production unit could be in orbit by 1985.

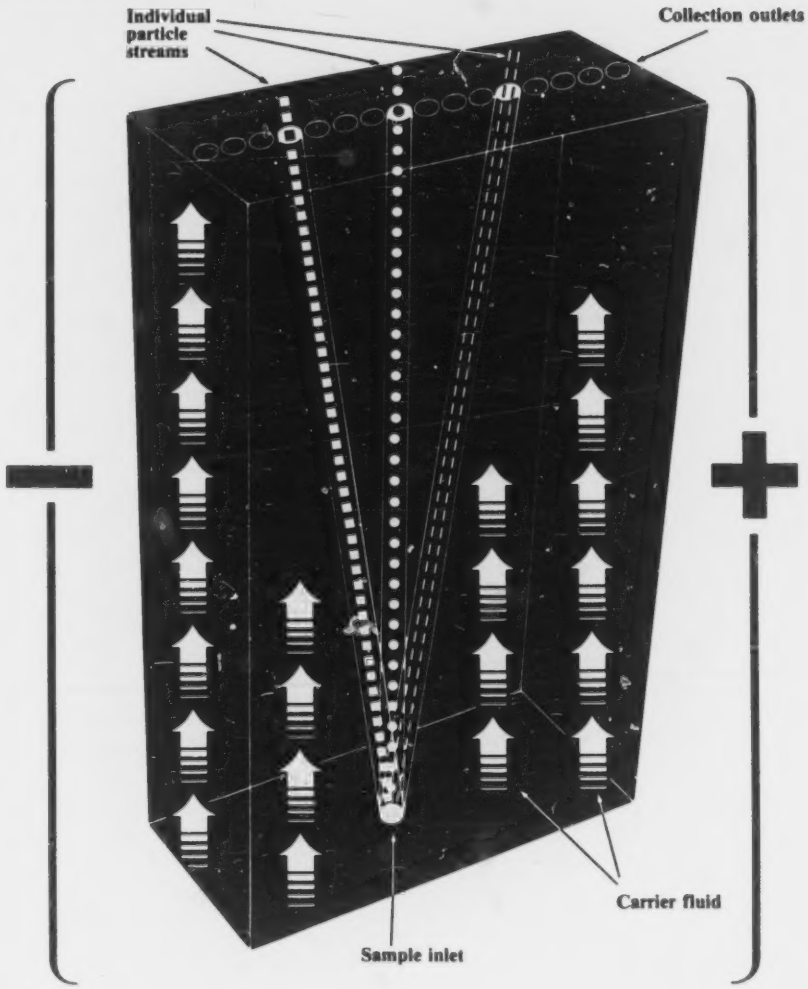
The basic electrophoresis process isn't really a new thing for lab scientists. It's been used for years in biology and medical laboratories to separate and analyze the components of such natural mixtures as blood serums and other protein mixtures.

The type of electrophoresis commonly used in labs is called static electrophoresis. It gets this name because the mixture to be separated (called the sample) is placed on a stationary object such as a porous gel plate. An electrical field is applied long enough to allow the differently charged particles to migrate to separate areas on the plate.

Although good separation is possible with static electrophoresis, only a small amount of sample can be separated at one time, usually about 0.01 milliliter. Hence, static electrophoresis is used for analysis and not for production.

Continuous flow electrophoresis is the process developed for the EOS project. In this process, a stream of sample material is continuously injected into a solution that carries the sample from the bottom of a long rectangular chamber to the top. As the sample flows through the chamber, an electrical field is applied across the flow. This causes the differently charged particles in the sample to move laterally at different rates, splitting the sample into distinct particle streams that exit through separate collection outlets at the top of the chamber.

In continuous flow electrophoresis, a sample of cells, enzymes, or other materials to be separated are injected into a fluid and carried— sans gravity—from the bottom to the top of a large rectangular chamber. As the sample moves through the chamber, an electrical field is applied across the flow. This causes the differently charged particles to separate and exit through separate collection outlets at the top of the chamber.



The continuous flow is the key to the process. Because the flow is steady, production is greatly increased.

However, in earthbound operations, production is severely limited by gravity. For the electrophoresis process to work properly, the sample must be light enough to flow with the carrier fluid in a steady, continuous stream. Because the sample fluid is generally much heavier than the carrier fluid, the sample must be highly diluted to flow properly. If the sample concentration is too high, gravity causes the sample stream to collapse around the inlet port and all is lost. Hence, in earthbound operations, lower concentrations of the sample are used to alleviate the gravity problem, hampering output.

The lack of gravity in space operations, on the other hand, allows greater concentrations of sample materials. The yield is thereby increased 100 to 400 times.

Gravity also causes uneven heating when the electrical field is applied across the electrophoresis chamber. This creates currents that make the particle streams waver back and forth, causing the streams to exit through the wrong collection outlets, seriously degrading purity.

Another gravity problem is "band-spreading." This phenomenon is the result of gravity acting on the slight density differences between the carrier fluid and the particle streams. Because the carrier fluid is lighter, gravity allows it to flow through the chamber more quickly, pulling the edges of the carrier stream faster than the center. This widens the stream and merges it with others, again jeopardizing the purity of the solutions collected.

Because of the heavier concentrations and fewer impurities, output on the first space shuttle was increased nearly 500 times over similar experiments on earth.

Of course, the experimental units used to date were only intended to verify the feasibility of operating the electrophoresis equipment in space. The small (580 pound) unit that Sally Ride used is not geared for commercial production.

A prototype production model is to be developed next. This unit, weighing 5,000 pounds, will have 24 times the capacity of the smaller unit. It will be flown in the bay of a 1985 shuttle. During the 1985 shuttle tests, scientists hope to obtain enough quantities of processed materials for Ortho Pharmaceuticals to begin clinical testing. Once the capabilities of the prototype production unit have been verified and FDA approval of the potential product has been granted, McDonnell Douglas plans to orbit a full-scale pharmaceutical manufacturing operation that would be serviced by NASA shuttle crews, who would collect the separated products and deliver raw materials. If all goes as planned, it will be there by the late 1980s.

What kind of material is being developed? Ortho Pharmaceutical is rather mum on that question. Company representatives claim they are protecting themselves against competitors and the possibility that the revelation will raise false hopes of "miracle cures." The firm acknowledges, however, that a number of biological products would be obvious candidates.

One would be interferon. Touted as a miracle drug, this substance seemed to be the answer to everyone's dream a few years ago. However, supplies made on Earth are limited and sometimes of low purity. Continuous flow electrophoresis machinery in space could solve such problems, but another procedure, biotechnological manufacturing with DNA manipulation, may be perfected before interferon gets into orbit.

Insulin-producing beta cells offer another good possibility. Beta cells, found in everyone's pancreas, produce insulin. Failure of insulin production leads to diabetes. Diabetes occurs when the million or so beta cells in the pancreas are damaged or destroyed. Diabetics must either inject insulin or take other drugs to keep their blood sugar levels normal.

Physicians have been experimenting with the use of beta cells for transplant surgery in diabetics, but testing has been hampered by a shortage of the cells. With the McDonnell Douglas electrophoresis device, the Washington University School of Medicine in St. Louis is stepping up its beta cell transplant research. Washington University and McDonnell Douglas are cooperating in space testing of samples taken from the pancreas of dogs to see if pure beta cells can be manufactured in space using electrophoresis.

Other potential products of the space drug plants include: growth-factor products for healing burns or surgical wounds; growth-hormone products used for pituitary gland problems such as dwarfism; antitrypsin products used for pulmonary diseases; and drugs used to thicken the blood for use in hemophiliacs.

While Ortho remains conservative about its objectives, McDonnell Douglas is publicizing each phase of the EOS project with great enthusiasm. Why not? The possibilities are out of this world.

Donald C. McLearn is a member of FDA's publications staff.

Have Rocket, Will Rent

Government policy has shifted in response to business eagerness to tap the vast potential of space.

By Del Marth

Reproduced with permission of the copyright holder from Marth, Del. Have rocket, will rent. Nation's Business, v. 71, Aug. 1983: 32-35.

QUEUES ARE FORMING at the nation's launching pads. Former astronauts, computer whiz kids, pharmaceutical researchers, geneticists, horticulturists, engineers—they are lining up with new rocketry and boxes of experiments, eager to cross the latest frontier.

"It is extraordinary how much money is going into new space industries," says Roger Selbert, a vice president of Security Pacific National Bank in Los Angeles. "We've had to add another vice president whose sole job is to handle inquiries from these new entrepreneurs."

President Reagan also sees the potential in the commercialization of space. In a directive issued in May, he said:

"Partnership between the U.S. private sector and the U.S. government will strengthen the U.S. space launch capability . . . contribute favorably to the U.S. economy and maintain U.S. leadership in space transportation."

No one agrees more than the private sector. But ever since the space age began some 20 years ago, hitching a ride has not been easy for business.

A major reason is that the U.S. government owns the launching pads and the tracking stations. It controls permits and licenses for space flights. It sets the price, and the schedule, for taking up commercial payloads.

The private sector, which helped create and refine the technology that made the United States pre-eminent in space, now wants part of the action. It will get it, according to the White House directive, because the government, like the private sector, sees the nation as a whole benefiting from the commercialization of space.

Key to the new policy is the ELV, the expendable launch vehicle—a rocket that cannot be used more than once. Before the advent of the re-usable space shuttle, all launches of payloads into space were achieved with ELVs like the Atlas, the Delta and the Titan. With the success of the space shuttle, the government planned to phase out ELVs later in this decade.

Under pressure from the private sector and because of increasing foreign competition in the payload-launching business, the government is now changing its mind. Not only does it see merit in using the ELV to handle commercial space experiments, but the National Aeronautics and Space Administration and the Defense Department have come to believe the ELV would make a fine backup for the shuttle.

There once was concern that the ELV would compete with the space shuttle. The shuttle does carry commercial payloads, particularly communications satellites, and NASA plans that it will continue doing so. But the shuttle's major mission remains government business.

Dismissing the concern over competition, Defense Under Secretary Herbert A. Reynolds told the House Subcommittee on Space Science and Technology:

"We are committed to the shuttle as the primary means for achieving access to space, and we do not believe the commercialization of ELVs will seriously affect the viability of the shuttle program."

He added that "the U.S. government must suppport and encourage the U.S. private sector to compete for the multimillion-dollar satellite payload and launch services market—or risk losing a portion of it to foreign competitors."

A project to stimulate that private-sector participation is under way.

"The time is right," says Kathryn

Little, director of development of the National Chamber Foundation in Washington, "to establish a unified industry position to encourage private commercial activity in space."

THE FOUNDATION is putting together a task force of 30 executives representing companies that have been—or want to be—active in space-related industries. Their assignment: compile a detailed, comprehensive package of recommendations on how to foster commercial development of space.

"These recommendations," says Little, "will be readily translatable into a legislative program." Issues to be covered include:

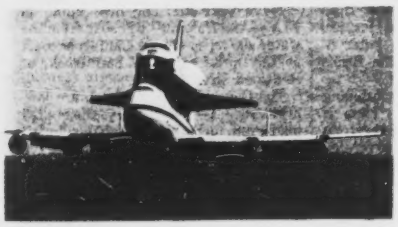


PHOTO: DAVID VALDEZ

The U.S. space shuttle, seen here atop a cargo plane, will remain "the primary means for achieving access to space," an official says.

- Ensuring open and competitive markets.
- Joint government/industry research and development.
- Designating a federal agency to oversee business ventures in space.
- International treaty obligations.
- New institutional arrangements to speed transfer of technology from government to business.
- Efficient commercialization of expendable launch vehicles.
- National security considerations related to private space activity.

The task force and its research activities will be supported by industry contributions. It is expected to take 12 months to put the package of recommendations together.

Little explains: "The companies that now have individual proposals before the government for commercial space activities face a largely unstructured bureaucratic environment, which is frustrating, time-consuming and expensive."

She says that a paramount concern of government officials is to avoid giving preferential treatment to particular companies and that a unified industry position will assure government decision makers that the task force proposals meet the business community's needs.

Five basic areas of commercial space activity are involved, says Gregg Fawkes, president of Pegasus Software, Inc., a computer software design firm in Washington, and the task force's principal researcher:

- Space transportation launch services, which include those firms now making ELVs or planning to build their own launch systems.
- Space materials processing, a fledgling industry using weightlessness in orbit to process silicon crystals, new and purer pharmaceutical drugs, and advanced alloys.
- Industrial research, which includes the study of processes in weightless conditions and the application of those research techniques on Earth.
- Communications, the largest of commercial space activities, which involves transmitting signals from fixed or orbiting satellites to Earth stations.
- Remote sensing, a field similar to the use of existing satellites to photograph and monitor the Earth's surface in search of natural resources.

Says Fawkes: "Our approach is quite different from other studies that have taken a look at potential space commercialization."

He notes that the NCF task force will be composed only of business people, representing a wide range of industries that might realize new growth opportunities in space. Many of the firms involved in the task force have not been active in space before.

"We will be addressing a very broad range of issues, from international treaties to government R&D policy," Fawkes continues. "This is necessary in order to establish a solid foundation for commercial activity in space."

The task force's recommendations will be very detailed, he says, since "general recommendations seldom get translated into action."

Fawkes says that Covington & Burling, a prestigious Washington law firm, "will be working with us to draft recommended language. So, for instance, if we find that treaty language needs to be amended to support private activity in space, we will propose some specific changes."

The NCF study will not try to "pick the winners" among countless new business opportunities in space. Rather, Fawkes says, the task force is concerned with making sure that an environment is created that will permit anyone who wants to explore new space applications to do so easily and efficiently.

"Space already provides many economic dividends and will do so on a much larger scale in the future," says Fawkes. "Space itself offers a whole new basis of scientific knowledge. And space applications drive a variety of other technologies—advanced communications, materials, energy cycles and robotics—that will be the basis of the next wave of economic expansion."

(Businesses interested in the work of the task force may write to Kathryn Little, Director of Development, National Chamber Foundation, 1615 H Street, N.W., Washington, D.C. 20062. Reports on the task force's progress will be released at frequent intervals, and the final report will be published in May, 1984.)

Commercialization of ELVs requires congressional approval of the continuing manufacture of the expendable rockets, which would be paid for and used by industry. The government would make available its launching facilities and equipment, at a price low enough to encourage their use.

The idea that the space shuttle could handle all space hauling for government and industry has been scrapped. Foreign competitors have successfully solicited U.S. corporations to send payloads up on the Ariane, an ELV launched from French Guiana by the European Space Agency. The agency is supported by both government and private funds from Western European nations.

ARIANE'S launch record to date has been spotty. Using an ELV similar to the Atlas, the European agency has sent up six rockets, but only four launchings have been successful. Nevertheless, the agency offers attractive rates for commercial payloads. Its marketing specialists in this country are convincing American firms that they can fly into space with the Ariane at a lower cost than on the shuttle, and on a precise schedule. The space shuttle has so far not managed to adhere to a precise schedule.

So aggressive has been the European agency that the Office of Technology Assessment, an advisory arm of Congress, reported last year that the United States was close to losing the lead in several critical areas.

OTA warned that the Europeans, and the Japanese as well, were taking a growing share of the market for satellite communications. Likewise, the report said, the U.S. lead in remote sens-

ing of the Earth's surface could be lost to the French by the middle of this decade. Also threatened was American pre-eminence in the processing of exotic metals and pharmaceuticals in space.

NOT SURPRISED that the foreign market is hustling American industry is William F. Rector, a vice president of General Dynamics. He estimates there will be a "need for launch services for approximately 245 commercial satellites between 1986 and 1995."

That represents, he says, more than $10 billion in potential launch vehicle revenue over the 10-year period. He points out that "schedule flexibility and reliability are ranked more important than launch costs by most commercial communications satellite users."

The United States is running less than a half-dozen shuttle flights a year and plans no more than 24 such flights annually in the 1990s.

James E. Beggs, NASA administrator, agrees with Rector that when "commercial launch requirements are considered in conjunction with planned Defense Department, NASA and other U.S. government missions, the demand exceeds the supply capability of the space shuttle in both the near and the far term."

The ballooning demand by business to get into space is particularly significant to Martin Marietta Aerospace. It manufactures the Titan, the granddaddy of ELVs. Discontinuing the Titan would cost "some 6,000 jobs for 220 suppliers in 25 states," says Peter B. Teets, general manager of the firm's space launch systems division.

But the economic effect of continuing the ELV system, not just the Titan, is even more wide-ranging, he says: "A proven lower-cost alternative to foreign space launch systems will reduce imports and contribute to our balance of trade. Likewise, the acknowledged U.S. leadership in space technology will be enhanced by commercial launch capabilities without burdening the federal budget."

He points out that these activities "directly translate into increases in high-technology jobs, with the usual multiplier effects on employment in other sectors of the country."

Some aggressive American entrepreneurs can't wait. While urging the U.S. government to embrace commercialization of space, they are building their own launch systems.

Space Services, Inc., of Houston, is one such firm. SSI, whose executive in charge of space flights is former astronaut Donald K. "Deke" Slayton, raised $6 million last year from foresighted Texans and launched its own rocket—the Conestoga I.

Next year another new name in ELVs—the Dolphin—will soar from the water 200 miles off the California coast as the initial effort of Starstruck, of Redwood City, Calif.

The Conestoga and Dolphin are low-orbit rockets—they carry their payloads into orbits 100 to 10,000 miles above Earth. Their launch pads are relatively inexpensive to build, at about $1 million, compared with launch facilities for a multistage Titan, at near $100 million. Titans and comparable rockets push sophisticated payloads, like communications satellites, into required higher orbits, the ideal being 22,300 miles, where satellites orbit at the same speed as Earth and thus remain above the same point constantly.

For the government to dismantle its ELV launching sites at Cape Canaveral in Florida and Vandenberg Air Force Base in California would be both wasteful and expensive, space experts now contend. The demand for ELV missions by industry, and as a backup for the space shuttle by the Defense Department, now seems clear.

BUSINESS IS aware that building its own launching facilities and ordering up a nonre-usable rocket like the Titan costs more per pound of payload than using the space shuttle—perhaps twice as much. But corporations that need high-orbit satellites are more concerned at present with getting aboard flights, and on schedule, than with initial cost.

Companies that need less expensive low-orbit payloads make up the market the new launch-system firms like SSI and Starstruck are going after.

They talk about using low-orbit satellites to prospect for minerals and oil, collect data on crops and forests and locate rail cars that railroads have lost track of. Texas oilmen foresee using low-orbit satellites to check on oil flow

The Shape of a New Space Policy

The Reagan administration is encouraging private sector participation in the space program, but the federal government will continue to play the dominant role for many years. The Reagan administration developed its partnership approach in announcing that the government "fully endorses and will facilitate commercial operations" of ELVs—expendable launch vehicles.

ELVs, the White House said, could help the United States "achieve routine, cost-effective access to space" while ensuring that the nation maintained "space transportation leadership."

Some elements of the new policy:

- The government will license, supervise and regulate American ELV operations "only to the extent required to meet its national and international obligations and to ensure public safety." On the other hand, commercial ELV operators must continue to comply with applicable laws and regulations—local, national and international—including security, safety and environmental requirements.
- The government will encourage the use of its own launch pads for commercial ELV operations. The government will have "priority use" of its facilities "to meet national security and critical mission requirements," although it will "make all reasonable efforts to minimize impacts on commercial operations."
- No government subsidies of private ELVs are contemplated, but the government "will price the use of its facilities, equipment and services consistent with the goal of encouraging viable commerical ELV launch activities."
- The government will encourage competition among ELV operators by providing "equitable treatment for all commercial launch operators" when government equipment and facilities are being sold or leased.
- If private operators wish to build their own launch facilities, they must submit their plans to the government for approval.

The White House directive emphasizes that despite the new policy of encouraging private ELV operations, the government "will continue to make the space shuttle available for all authorized users—domestic and foreign, commercial and governmental," with prices to remain stable through fiscal 1988.

38-036 O - 84 - 44

from their wells without having to send someone to read the meter.

If these small launch systems succeed and the government continues the ELV system in cooperation with industry, rockets carrying manufacturing and testing equipment will become commonplace. They will spawn a space traffic industry similar to the one that has grown around commercial airlines.

Orbital Systems Corporation, of Chicago, is an example of a new firm entering space commerce.

Three former Harvard graduate business school students—David Thomson, 29, Scott Webster, 30, and Bruce Ferguson, 28—undertook a study while at Harvard of how the government might encourage private investment in space operations. Their research prompted them to borrow funds and create the Chicago firm. Their product: a rocket to launch commercial satellites from the orbiting space shuttle into a higher orbit.

NASA has contracted with them to produce the rocket, convincing Thomson, the firm's president, that "space is the next commercial frontier."

SUCH VENTURES delight former Commerce Secretary Philip Klutznick. As head of a panel from the National Academy of Public Administration in Washington, he helped prepare a NASA-commissioned report on encouraging business ventures in space. His conclusion:

"The government must involve American companies in our space program if we are to justify the heavy investment the American people have made in the last quarter century."

Klutznick's panel recommended that the government make launch schedules predictable and reliable, grant full rights to inventions and proprietary information to private parties in joint endeavors and support private financing of space vehicles.

Congress listened in May to a parade of government officials and business leaders who unanimously supported the President's policy of sending Yankee ingenuity into space. Before the House is the Space Commerce Act, a bill to spell out guidelines for commercial exploration and to designate a government agency—the Defense Department, the Commerce Department or the Federal Aviation Administration—as the clearinghouse.

Says Space Services, Inc., Chairman David Hannah, Jr., a member of the National Chamber Foundation task force and the visionary behind the Conestoga rocket system in Texas: "There are going to be markets for space business that we haven't even guessed at."

To Hannah and other entrepreneurs, the upcoming encounter with space business is, like space itself, without limits. □

NASA's Next Mission

Big Business in Space

As it celebrates its 25th year, the agency is under pressure to shift its emphasis away from exploration and toward commercial and military uses of outer space.

By John Noble Wilford

WHEN THE COUNTDOWN NEARS THE final few minutes, a hush settles over Cape Canaveral. It is dark, a couple of hours after midnight on Aug. 30, and as if in response to some vestigial mammalian instinct, the senses grow more acute. The air smells of damp subtropical decay and, one imagines, sleeping alligators. I am peering across the lagoon out to the palmetto and to the sandy flats running to the Atlantic shore, three miles away, where the space shuttle Challenger stands on its truncated pyramid like a monument bathed in ceremonial light.

Its image shimmers in and out of focus. Sometimes in the dense, humid air the xenon-lighted Challenger looks like a mirage, which gives it a mythic aspect. We are looking and waiting for the greater light, the sudden dawn of ignition.

Waiting for the moment of launching, in the hushed atmosphere of anticipation, I never fail to sense something beyond sight and smell, something else — echoes. The echoes of the old days of space flight, the struggling days and glory days when we first became a spacefaring people.

Hard as it is for some of us to believe, on Oct. 1, the National Aeronautics and Space Administration will be marking the 25th anniversary of its creation, and so I am even more attuned to the echoes from the past. Over the years, I have seen 30 crews of astronauts embark on space voyages and dozens of tests of new rockets and launchings of craft to provide new communications links, survey the earth and the heavens and probe the planets.

Reproduced with permission of the copyright holder from "NASA's next mission: big business in space," by John Noble Wilford, September 18, 1983, New York times magazine, pp. 47, 50, 83-84, 86-88, 90.

Back in the early days, waiting for liftoff was more often than not an exercise in futility. Some gizmo would balk at the last minute, and the launching would be scrubbed until another day, another week. Once, frustrated reporters were reduced to writing about the murder of a local cocktail waitress, calling it "the only successful shot fired here in weeks." Or the rocket would take off in the wrong direction and have to be destroyed in midair. People from those days still talk of a missile called Snark, which had the unhappy habit of taking off and plunging into the nearby Banana River so often that they began speaking of the Snark-infested waters.

In time, however, the countdowns usually went like clockwork and the destinations kept getting farther and farther away from the Banana River. It was no longer achievement enough just to get something in orbit. On the strength of the raw, gravity-defying power of the Saturn 5 rockets, whose rattling reverberations still echo in the mind, we reached the moon. Our automated surrogates ventured out to Mars, Jupiter, Saturn and beyond. We saw these worlds for the first time as worlds, not as baubles of reflected light in the sky. One of the spacecraft we bade farewell to at Cape Canaveral more than a decade ago, the hardy Pioneer 10, has cruised beyond the outermost planets, bound for interstellar space.

John Noble Wilford writes about space and science for The Times.

These were achievements to match the exuberant rhetoric of those early days. Reaching for a metaphor for the new experience in unfamiliar realms, President John F. Kennedy in 1962 spoke of space as "this new ocean" and of those who set sail on it as spacefarers embarking on "one of the great adventures of all time." This generation, he added, "does not intend to founder in the backwash of the coming age of space." The words breathed of romance and daring, of new frontiers to test the resolve of a people shaped by the experience of mastering frontiers.

T-minus-31 seconds and counting. Thirty-one seconds to go. The computers are running everything now. The thunderstorms have passed, the sky is opening up after a 17-minute rain delay, and everyone expects the launching to be flawless. Down the line. A piece of cake. Those fuel cells and auxiliary power units might send off a few alarms in the cockpit. Not to worry. A few heat-shielding tiles might fly loose during ascent. The shuttle will endure such things.

It is a tested machine. A fantastic flying machine, the astronauts say. The shuttles, the world's first re-usable spaceships, have been flying since April 1981. Part rocket, part spacecraft and part airplane, they represent an attempt to make travel on the new ocean more economical and more routine.

When development of the shuttles began in 1972, the nation had changed and so had its language of expectations. Another President, Richard M. Nixon, heeding the more constrained spirit of the time, had said: "With the entire future and the entire universe before us, we should not try to do everything at once. Our approach to space must be bold — but it must also be balanced." In the lean years that *(Continued on Page 50)*

NASA

Continued from Page 47

followed, throughout the 1970's, NASA struggled to build the shuttles on a shoestring, sacrificing the kinds of exploits that had so enlarged our sense of wonder. But the shuttles got built — two are now in service, Columbia and Challenger, and two more are under construction, with the possibility of a fifth being started — and in the early hours we wait for the eighth launching of one of these revolutionary spaceplanes.

The sudden dawn comes up at 2:32 A.M. — like thunder, Mr. Kipling, literally thunder. Orange flame lights up the sky for a few hundred miles, as if calling attention to the advanced state of American space technology. The explosions of energy shake the ground and reverberate through the humid night. New echoes. As the Challenger disappears out over the Atlantic, with its five astronauts, it climbs into an orbit of the earth carrying a communications-weather satellite for India, stamped envelopes for eventual sale by the Postal Service, an experiment in drug processing for industry and assorted other experiments.

The old echoes give way to a dawn of recognition. This is no adventure in exploration; this is a freight run.

Space flight is still no ordinary undertaking; it is fraught with risk, and never ceases to inspire awe. But more and more its character is changing. The era of space exploration, the time of finding out what is out there and learning to take the first steps in traversing this new ocean, the time of doing what can be done because it can be done, without economic constraints, has ended. We have demonstrated that we can sail the new ocean reasonably well, and, having done so, we tend to look upon the endeavor in less heroic terms. The familiar is less romantic. We have transformed some of our early visions into reality.

Now space is seen in more mundane, workaday terms as a place to be used and space flight as a means of exploiting this place — the new-ocean metaphor is no longer invoked — for commercial gain, military advantage and construction of orbiting outposts to handle the traffic in people and machines that is sure to follow. Footprints may be planted again on the moon and someday on Mars. A few craft will still go forth on missions of scientific discovery. But if current activities and proposals are an indication, the major thrust ahead is to incorporate space into the economic and political scheme of things on earth.

Thus, NASA finds itself in a critical time of transition as it begins its next 25 years as the institution primarily responsible for America's civil space program. The agency finds itself under increasing pressure to make space flight a paying commercial proposition in which private industry plays a larger role; to work more closely with the Defense Department, even at the risk of losing some of its independence and compromising its reputation for conducting an open program for all the world to share; to spin off some of its civilian operations to other Government branches; to maintain America's pre-eminence in space in the face of growing international competition, not just from the Soviet Union but from Western Europe and Japan, and somehow to establish for the nation a new vision of its future in space.

But the agency also finds itself preparing to meet a challenge of the kind it likes best, an ambitious engineering project at the forefront of technology. All signs indicate that the Reagan Administration is close to authorizing NASA to proceed toward its long-desired goal of assembling a permanent complex of laboratories, observatories, microgravity "factories" and living quarters in earth orbit — in short, a space station. Resonating through these grand plans are echoes from science fiction, echoes of the future.

□

A new Presidential metaphor reflects current attitudes that shape what NASA can aspire to and what the nation's space program is likely to be for decades to come. On July 4, 1982, President Reagan was welcoming home the crew of Columbia's fourth and final test flight. Standing in the desert sun at Edwards Air Force Base in California, he said: "The fourth landing of the Columbia is the historical equivalent to the driving of the golden spike which completed the first transcontinental railroad. It marks our entrance into a new era. The test flights are over, the groundwork has been laid, and now we will move forward to capitalize on the tremendous potential offered by the ultimate frontier of space."

The metaphor is no doubt apt, or will be made so by the vigorous efforts of the Reagan Administration and NASA's leadership. True to their official name, the Space Transportation System, the shuttles and ancillary equipment are to be the transcontinental railroad of the space age, a vital link between earth and a region considered to be ripe for a multitude of uses and, perhaps, someday, for human occupation. Just as regular railroad service helped open up the American West, regular shuttle service could open up space to human activities on an extraordinary scale — the establishment, as the President said, of "a more permanent presence in space." From four flights this year, the shuttle traffic could escalate to 11 flights next year and 20 a year by the end of the decade.

On the same occasion, the White House released a summary statement of the Administration's space policy. Heading the list of "basic goals" was one to strengthen the nation's security through space. But more emphasis than ever before was placed on efforts to obtain economic benefits "through the exploitation of space" and to "ex-

pand United States private investment and involvement in civil space and space-related activities." Science and exploration were mentioned, though hardly emphasized.

These words about economics produce the echoes to which NASA nowadays responds. The business of the space enterprise will become more and more business. A few days before the Challenger's launching, Lieut. Gen. James A. Abrahamson, NASA's shuttle chief, said: "We're moving into a time when space is going to become much more of a commercial endeavor, is going to become a place where we'll be doing many more things that will have applications to people on earth. I see it as a time when businessmen around the world are finding that commercial space enterprises are well worth the risk and offer a real potential for profit."

This is not merely a reflection of the influences from a business-oriented Republican

(Continued on Page 83)

NASA

Continued from Page 50

Administration. Some of the first tentative steps toward exploring commercial prospects in space were taken by the Carter Administration. It was perhaps inevitable, given the nature of people and their approach to new frontiers, that after the period of exploration there would follow a period devoted to possible exploitation. First, we went out to space, and now, in a sense, we are trying to embrace it and bring space down to earth. We may be left for a time with only the echoes of the testing and exploring times, but — with a sigh, perhaps — we must accept the fact that the American civil space program is growing to maturity. It has passed through the joys and crises of precocious childhood and now is being called upon to do grown-up things, like earn a living and establish permanent roots in space.

The leaders of NASA are striving to reshape the agency to respond to the railroad metaphor and also maintain the can-do fervor that has motivated its best engineers and managers. It is not an easy task. If the agency does not get into step with the new economic and political realities, especially regarding its relations with industry and the military, it could wind up on the periphery of the space enterprise it did so much to mobilize. Already, the Defense Department's space operations have surpassed NASA's in annual spending — $8.5 billion, compared with NASA's $7 billion — and the Reagan Administration plans to increase military space spending by more than 10 percent a year over the next five years, a greater rate of increase than for the rest of the department. The Commerce Department's National Oceanic and Atmospheric Administration has assumed the operations of weather and earth-resource survey satellites. And years ago, in the first and as yet only profitable commercialization of space, private industry took over communications satellites.

If, on the other hand, the agency does not continue to have challenging goals, it could lose many of its best engineers and managers. NASA is already much smaller than in the Apollo days, with a work force of 21,000 compared with 36,000 in 1968. Many of the brightest engineers, attracted to NASA during the Apollo Project, now hold critical middle-level management positions; without new challenges, they would be tempted to leave. There are signs that the "brain drain" is beginning.

By background, today's NASA leaders seem suited to the new era of exploitation. Unlike previous administrators — two university presidents, a lawyer-politician, an engineer and a physicist — the present NASA administrator, James M. Beggs, is a former business executive. He was the executive vice president of General Dynamics Corporation just prior to taking the job in 1981, but before that had held management posts at NASA and the Department of Transportation. The deputy administrator, Hans Mark, is a former Secretary of the Air Force. The associate administrator for space flight, who runs the shuttle program, is General Abrahamson; he had overseen the F-16 jet-fighter development. Though there have been businessmen and generals in NASA's management before, now they seem to be there with the mission of establishing stronger ties with business and the military.

When Mr. Beggs took over, he set himself one major long-range goal: to win approval for NASA to embark on the space-station project. In announcing preliminary plans for the station this summer, Mr. Beggs said: "It will open up commercial opportunities we have not dreamed of; it should improve our national security; provide more sophisticated science, and be a source of international cooperation. If the United States does not take this step, we will lose our pre-eminence in space." That is, the station was to be the centerpiece in NASA's response to Administration pressures for economic and military exploitation of space — as well as to the agency's own institutional momentum. Such an under-

taking would keep NASA where its engineers like to be, doing the big project.

□

Anyone who saw the movie "2001: A Space Odyssey" has a notion of what an orbiting space station could be like: a huge white-spoked toroid slowly revolving in the great beyond, inhabited by astronauts and engineers who operate instruments of high technology and dispatch craft to the more distant reaches of space. A space station was high on NASA's post-Apollo planning agenda, but nothing came of it except the experimental Skylab, operated in 1973-74. Plans for a more ambitious station had to be set aside in favor of the shuttle, which NASA engineers accepted because they had to, budgets being what they were, and also because they envisioned it as the ferry that would someday shuttle back and forth between earth and the space station.

The White House is expected to make a decision on the space station very soon, perhaps early enough so that NASA, if the decision is favorable, could get some start-up money in next year's budget. But NASA's immediate plans are more modest than the 2001 station. According to a NASA task-force study, the core of the station would be a large cylindrical "house," where four to six astronauts, engineers and scientists would live, conduct their work and operate the rest of the station.

This habitat would be equipped with ports into which the shuttles would dock. Attached to the habitat would be additional chambers for prototype orbital factories — places for processing metal alloys, crystals for electronics, drugs, vaccines and other industrial products that presumably could be made better, or only, in the microgravity vacuum of space.

Extending out from the habitat, at the end of long girders, could be the antennas, solar-power panels and other modules containing experiments. Another platform for experiments, uninhabited, could fly nearby so that it could be serviced by the astronauts and yet be free from the vibrations and contaminations of the main station. If development were to begin next year, Mr. Beggs said, the basic elements of the station could be aloft by 1991 at a cost of $9 billion.

Later, the station could be added to, module by module, beam by beam, much like a Tinkertoy set, until it accommodated from 12 to 18 people and spread out like an orbital industrial park and service station for refueling and overhauling satellites and interorbital tugs. A second space station, probably uninhabited, might also be placed in a polar orbit for earth sensing and for military reconnaissance and command operations. So far, however, the Pentagon has been cool to NASA's space-station plans. It is supporting NASA but says it has not identified a single military job that could be done better by a space station than by conventional spacecraft. In time, more active Pentagon backing may be vital to the project, as it was in winning continued financial support for the shuttle.

By 1991, the Soviet Union will probably have its own large space station in orbit. For the last decade, Soviet efforts have focused on flights of its small Salyut stations, each of which has remained in orbit several years and served as home for crews for as much as six months at a time. The Salyut 7, now in orbit, was doubled in size last June by the addition of a module, and at the time, Soviet officials reiterated their goal of creating "long-lasting, manned orbiting space stations."

But NASA officials are not stressing Soviet competition so much as the prospects of inaugurating an extraterrestrial industrial revolution through the space station and other programs. "No longer is it a question of whether space has commercial promise," said Mr. Beggs, "but rather how best to proceed to maximize that promise for national economic well-being. I think that is a very significant point in the history of this agency and the history of this nation."

In keeping with the Administration's goal of getting private investors more involved in space, NASA announced recently that a 1986 shuttle mission would be devoted entirely to industrial experiments. A NASA-funded study found that 84 companies were interested in doing 244 experimental and commercial projects in orbit. The first working example, which has already been on four shuttle missions, was a separation process known as electrophoresis. Developed by the McDonnell Douglas Corporation in conjunction with Johnson & Johnson, it successfully tested methods of making ultrapure pharmaceutical products, such as vaccines and a possible replacement for insulin.

For the first time, moreover, private companies are putting venture capital into space flight other than satellite communications. Fairchild Industries plans to build its own small unmanned orbital platforms, to be deployed by the shuttle, and to rent space to other companies for research and manufacturing. A West German company, Messerschmitt-Bolkow-Blohm, has already built a similar craft. A group of Texas investors is testing a private space-launching rocket. Three young graduates of the Harvard Business School recently set up their own company, Orbital Systems Corporation, and received from NASA exclusive rights to develop and market a propulsion system for launching satellites from the shuttle. And several large companies are interested in the Reagan Administration's plan to allow private industry to buy Delta, Atlas and Titan rockets and launch them for hire.

A standard arrangement to get private industry thinking space is an exclusive joint-endeavor agreement between NASA and a company with an idea that has commercial potential. The agency offers the company a free ride on the shuttle for as long as its work is in the research-and-developmental stage. Three companies have signed such deals and several dozen others have expressed interest. When the manufacturing process reaches a production stage, the company begins paying a hauling fee, which could be as much as $5 million for each shuttle flight. Shuttle fees run about $42 million for a payload that takes up the full cargo bay. A customer can reserve the entire 60-foot-long bay or part of it, and pay accordingly. These fees are expected to increase substantially in 1985 to reflect the true costs of the shuttle flights.

Other arrangements are being negotiated on a case-by-case basis. Such high-risk research-and-development ventures also enjoy substantial tax deductions for the investors. There have been some exploratory talks about having a private company pay for an additional shuttle in return for an arrangement with NASA to be the shuttle marketing agent.

□

There are, of course, critics and skeptics of the new plan for NASA. They fear that NASA may be overselling the prospects for significant commercialization. NASA, they feel, lacks sufficient assurance of funding to carry out the projects that are envisioned as justifications for the space station. At the same time, it wants to jump into another big engineering endeavor that could, as with the shuttle in the 1970's, wreck chances for a more balanced program of science exploration and commercial activities.

They also believe the Reagan Administration is being hasty in its moves to turn over some segments of space activities to private industry. A recent study by the National Academy of Public Administration, composed of 294 scholars and Government administrators, recommended against a transfer any time soon of the space shuttles to full operation by a private company.

A proposal by the Reagan Administration to hand over to private industry all weather satellites and the Landsat earth-resource survey satellites, now operated by the National Oceanic and Atmospheric Administration (after they were developed and tested by NASA), has run into heavy opposition in Congress. Critics charge that, in the case of the weather satellites, the Government would be setting up a private monopoly whose sole customer would be the Government itself. They say the Landsat divestiture makes even less sense. According to a study prepared under Government contract by Earth Satellite Corporation and Abt Associates, an organization of research and development consultants, only substantial subsidies and Government-guaranteed data purchases could produce a profit for a private earth-resource survey company for many years to come.

Some projected commercial uses of space are the processing of metal alloys, crystals for electronics, and drugs and vaccines.

A source of deeper concern is the shuttle itself. As successful as the flights have been, it remains to be seen whether the shuttles can live up economically to their advance billing. In the original projections, the four-shuttle fleet was expected to fly 560 missions over a 12-year period, with each vehicle being able to land, be serviced and take off again in two weeks. This was a totally unrealistic prediction, it turns out, conceived in part to justify the shuttle to Congress and the public. The more often the shuttles flew, the less each flight should cost — a matter of overhead divided by volume. "That was the phoniest Mickey Mouse economic analysis that ever went on record," said Richard D. DeLauer, Under Secretary of Defense for Research and Engineering.

Shuttle officials have long since abandoned predictions of two-week turnarounds. Their present goal is a total of 24 launchings a year by 1988 for the fleet of four shuttles, 30 by 1990 and 40 by 1992. A recent study by the National Research Council concluded that the chances of reaching 30 launchings by 1990 were "impossible or highly improbable" because of engine-maintenance and refurbishment problems. Still, General Abrahamson foresees a "crossover point" in shuttle launching-rate economics around 1988. He said that with a higher launching rate, higher customer fees based on realistic costs and more efficient operations, the "loss-leader part of the program" should then be behind NASA.

Unless the shuttles pull out of the red and can produce annual revenues of at least $2 billion, as Mr. Beggs has forecast, NASA may be hard put to support a more aggressive program in the future. Although NASA has received modest budget increases in recent years, to pull out of its 1970's doldrums, its current annual budget of $7 billion has less than 40 percent of the purchasing power of its allocation in 1966, the high point of the Apollo mobilization, when there was enough money not only for going to the moon but also for initiating the spectacular planetary expeditions. Skeptics, particularly scientists, say from bitter experience that if anything has to go to finance the space station, it will likely be NASA's science programs.

NASA will be making its push for accelerated space-station funding at the same time it is supposed to be reviving its planetary exploration program. After a lapse of six years, in which no major new planetary missions were authorized, the Administration this year finally approved a program to send a spacecraft to map cloud-shrouded Venus by radar in 1988. On the drawing boards are missions in the 1990's to orbit Mars to study the planet's geology and climate, to visit the vicinity of a comet and asteroid, and to probe and map Titan, the large satellite of Saturn. Other proposals include missions to bring back samples of Martian soil, collect fragments of a comet and to orbit the moon to prospect its resources for exploitation.

Under a plan developed earlier this year by a committee of leading scientists, such expeditions could be supported with an investment of $300 million a year over the next two decades, less than 5 percent of NASA's budget. That would be half again as much as planetary exploration's current budget, but considerably less than spending a decade ago. Reaction to the plan has been favorable at both NASA and the White House.

Not to have a commitment to future missions would be to turn away from one of the most exciting enterprises of our time — our voyages of discovery in the solar system. Shuttles and space stations may expand human activities in space, but the little craft that visit other worlds with their cameras and inquiring sensors expand our knowledge and inspire a sense of wonder about our place in the universe. While the shuttles make their increasingly routine freight runs in the years to come, Voyager 2 will be flying by Uranus and out to Neptune, and the orbiting space telescope, scheduled to go into operation in 1986, will be extending our vision of the universe.

Scientists have also noted that NASA's budget crunch during the shuttle buildup cost dearly in missed opportunities. A "grand tour" of the planets, with craft far more sophisticated than the Voyagers, was canceled. The United States pulled out of an expedition, with the European Space Agency, to orbit the poles of the sun. No American satellite will be going out to rendezvous with Halley's comet in 1985-86, as had been proposed, leaving such explorations to Europe, Japan and the Soviet Union. Even the shuttle suffered. The original plan, abandoned because of costs, was to make it a completely re-usable vehicle, and thus more economical to operate, instead of having to replace its booster rockets for each launching, which is now the case.

NASA's leaders have sought to reassure scientists of their commitment to scientific exploration in the space-station era. They note, for example, that the station would

Unless the shuttles pull out of the red and can produce annual revenues of at least $2 billion, NASA may be hard put to support a more aggressive program in the future.

be a key element in the mission to obtain samples of Martian rock. The samples might be returned there to be processed so that Martian microorganisms, if any exist, would not contaminate Earth. The station could also be a port of embarkation for manned flights back to the moon or to Mars. "If such a base were in orbit by the year 1991," wrote Mr. Beggs in the journal Spectrum, "the United States would be back on its way to the moon by the year 2000."

Out of this time of transition for NASA, for all the emphasis on the practical aspects of exploiting space, may emerge a larger vision of what America should aspire to in space. We can now contemplate greater aims because we have the technology, thanks in large part to Apollo in the 1960's and the shuttle development in the 1970's.

George A. Keyworth 2d, President Reagan's science adviser, went to Washington two years ago with discouraging words for NASA's ideas about big ventures. But he has changed his mind. Mr. Keyworth has decided it is time to return to a bolder approach to the space program and to "inject a new sense of vision into U.S. space exploration." Space, he says, is "a place to be careful, but not to be timid." Some of the less-timid initiatives he has in mind include the development of shuttlelike vehicles to fly from the space station, which he sees as eventually becoming a transportation hub, the development of colonies on the moon and the launching of astronauts from the space station to Mars.

These words sound like echoes from the glory days earlier in NASA's first 25 years. Whether the spirit of Apollo can ever be rekindled is questionable. NASA no longer has the political clout it had then, and the nation is probably in no mood for what might seem to be technological extravagance. But we are a spacefaring people now — our travels have only begun. ■

PATRICIA E. HUMPHLETT

PROPOSED SALE OF LANDSAT AND THE WEATHER SATELLITES

Reproduced from Humphlett, Patricia E. Proposed sale of Landsat and the weather satellites. Congressional Research Service Review, v. 4, Oct. 1983: 12-14.

On March 8, 1983, President Reagan announced that he supported transferring to the private sector all U.S. civil remote sensing satellites including Landsat, the weather satellites, and future ocean sensing satellites. While an endorsement of the transfer of Landsat had been expected, the inclusion of weather satellites in the announcement took the user community by surprise and raised a storm of controversy. Users of weather satellite data were concerned that they would lose access to it or have to pay for what the Government now disseminates for free.

In Congress, some Members were concerned that the Administration would transfer the satellites without their approval and introduced legislation to require congressional approval of any sale or transfer of remote sensing satellites. The Administration has since indicated that it has no intention of acting without the advice and consent of Congress.

Despite that assurance, some Members and some user groups continue to raise questions about the private sector's ability to provide system continuity, to meet national security requirements, and to operate the system without increasing Government and user costs. The Administration expects to answer these and other questions through a request for proposals (RFP), which the Department of Commerce will issue to industry in late November.

Landsat is a remote sensing satellite that returns data which can be processed into images or digital data for use in geology, agriculture and other areas.

Landsat was developed by the National Aeronautics and Space Administration as an experimental program, and, although the program was a technical success, no long-range plans were made to convert it to a more user-sensitive operational system. The lack of Government commitment to long-range plans has surpressed a Landsat data market and data sales do not meet procurement and operations costs. The Landsat system costs (on average) $75-$100 million a year to build and about $50 million to operate. Federal and non-Federal data purchases, although difficult to estimate, average less than $20 million per year—a net loss of $100-$125 million annually.

In 1979, seven years after the first Landsat began returning data, President Carter transferred Landsat operations to the National Oceanic and Atmospheric Administration (NOAA) in the Department of Commerce. At the same time, he requested NOAA to study whether the private sector could operate a land remote sensing system in the future.

The Carter administration planned to build and launch Landsat 4 and three follow-on satellites to continue Landsat as a Federal program through 1994. It was thought that a Government commitment was necessary to encourage private sector investment in data interpretation equipment, training, and long-range studies, and thus to increase the data market. The Carter administration hoped that Landsat data sales would be large enough by 1994 to meet satellite procurement and operations costs, and that the private sector would then be able to operate the system for profit.

The Reagan administration also wants to transfer Landsat to the private sector, but trimmed six years off the Carter schedule. The Reagan administration currently plans to fund only one more satellite to be launched after Landsat 4 fails. Landsat 4 is failing prematurely, but Landsat 5 is expected to last three years, continuing the Landsat program through 1987. According to the Administration, the private sector is better equipped than the Government to expand the Landsat data market; the private sector has the profit incentive and experience in marketing new products.

Furthermore, the Reagan administration supports the view that the Government should not produce goods or services where the private sector can provide them more cheaply and efficiently. A potential problem with this plan is that, if the private sector does not take over Landsat, the program will end in 1987. Furthermore, since it takes four years to build a Landsat, even if the Government decides to stay in the program, there will probably be a gap between satellites; a private firm would also have a problem delivering a satellite without a data gap.

President Reagan endorsed the commercialization of the weather satellites as well as Landsat. Again, this policy is based on the view that the Government should not compete with the private sector if the private sector is capable of providing the same services. According to Secretary of Commerce Baldrige, the commercialization policy decision included the weather satellites because of the economic risks involved in a private sector Landsat operation; weather satellites, with an established user market, can provide the revenue base that a private operator needs to develop a Landsat market.

The Reagan administration also hopes that a combined Landsat and weather satellite operation will provide better data at a lower cost. Currently, the Communications Satellite Corp. (COMSAT) is the only firm that has proposed commercializing both Landsat and the weather satelliites. It is unclear whether enough other firms will be interested to ensure a competitive bidding process on the satellites. In addition, once the satellites are transferred to the private sector, it will be difficult for another firm to enter the market, thus creating a monopoly. Critics have questioned whether such a monopoly would have the incentive to develop the Landsat data market or would be in the Nation's best interest.

The Reagan Administration has formed several groups to study the commercialization of Landsat and the weather satellites. The Land Remote Sensing Satellite Advisory Committee, the Business Evaluation Committee, and the Technical Evaluation Committee all evaluated responses to a request for information (RFI). The Commerce

Department issued the RFI in September 1982 for industry comment on the feasibility of Landsat and weather satellite commercialization. The Cabinet Council on Commerce and Trade, chaired by Secretary of Commerce Baldrige, has also studied this question.

The Land Remote Sensing Satellite Advisory Committee, composed of individuals from outside of the Federal Government, reviewed the responses to the RFI. In November 1982, the committee issued a report which emphasized the need for Landsat continuity and recommended that the Government transfer only the space and ground segments of the land and/or weather satellites up to and including the receiving of the raw, unprocessed data. Under this plan, many firms could then enter the data processing, enhancement, and product development end of the Landsat system.

Two Government interagency panels also evaluated the RFI responses. The Business Evaluation Committee concluded that the user market for Landsat is not presently large enough to support a private operation without a Government subsidy. It therefore recommended a gradual commercialization, beginning with the value-added segment. The Technical Evaluation Committee raised several national security concerns and cautioned that a monopoly might harm Government interests.

The Cabinet Council on Commerce and Trade met several times to discuss whether Landsat and/or the weather satellites should be transferred to the private sector. When it met in April 1982, the Council decided that the weather satellites should remain under Government control for national security reasons. The Department of Defense has raised some concerns about the transfer because of the close relationship between the civil and military weather satellites. When the Council met again in December 1982, however, it decided that national security issues could be resolved and recommended that all U.S. civil remote sensing satellites be transferred to the private sector. This recommendation was forwarded to, and later approved by the President.

Following President Reagan's announcement, a Source Evaluation Board was formed to develop and issue an RFP. There are three committees under the Board which will provide: a business evaluation, a technical evaluation, and legislation to pass through the Congress once a final decision is made. According to the current schedule, the Source Evaluation Board will release a draft of the RFP in late-September and invite industry and Congress to comment on the draft through October.

A final RFP will then be released in November or December 1983 and industry will have three months to respond. Following a three month review of the proposals, the Board will send its recommendation, with the best offer or offers from industry, to the Secretary of Commerce. If the Board does not believe that any of the proposals from industry are acceptable, it can also recommend that no transfer be made. The Secretary will then make his final decision, probably in May or June 1984. Based on the final proposal, the Source Evaluation Board will draft legislation to pass through the White House and then to Congress. With congressional approval, the satellite systems could then be transferred to the private sector.

Congress will continue to be involved in resolving some of the issues surrounding the proposed transfer of remote sensing satellite including: system continuity, Government and user costs, the possible creation of a monopoly, Federal subsidization of Landsat, allegations of a Government "give away" of valuable systems, national security, foreign competition, and international cooperation. Current plans to launch only one more Landsat and the long lead time required to procure another Landsat will make it difficult to ensure Landsat continuity. Whether the program is taken over by the private sector or continued by the Government, there will probably be a one year data gap. If the private sector does not take over, the program could end in 1987.

There is also some concern that a private land and weather satellite operator will increase Government and data user costs, especially in the short-term, and the Congress and the Administration will have to decide what costs are acceptable. Critics have warned that a private operator with a guaranteed Government contract could become a monopoly and restrict, rather than encourage, competition in these fields. Objections have been raised that the Government is selling the weather satellites only to convince the private sector to take over Landsat, so that the weather satellites would essentially subsidize Landsat. Should the users of weather satellite data subsidize the development of a commercial land remote sensing system?

Furthermore, because the Government has invested $1.6 billion in the systems, and will receive far less from the private sector, some have called the proposed sale a Government "give away." Should the Government expect to recoup its R&D investment in remote sensing? How should the value of the systems be assessed?

The Defense Department has raised some concerns about national security (primarily because of its use of civil weather satellite data) and will place

some restriction on a private weather satellite operator. The Defense Department may also restrict future land remote sensing operations to ensure national security.

Landsat will face some foreign competition after the French launch their land remote sensing satellite, SPOT, in 1985. Without a firm commitment to a future land remote sensing program, the United States could lose some of its foreign and domestic Landsat data market to the French. If Landsat is not transferred, will the Government commit enough funds to keep Landsat competitive in the international marketplace?

Finally, the United States has encouraged foreign countries to use Landsat data and has freely exchanged weather data with the international community. The United States will have to decide if it wants to continue this international cooperation and what effect commercialization will have on these policies.

Should We Make Products on the Moon?

Jet Propulsion Laboratory, CalTech

By the turn of the century, just a good development cycle away, commercial needs for large amounts of certain materials in Earth orbit may justify producing them on the Moon

THE AUTHORS

WILLIAM F. CARROLL, left, member of the Technical Staff in JPL's Applied Mechanics Div., has been involved in materials R&D and applications for JPL lunar and planetary spacecraft, advanced space mission concepts, and biomedical and solar-energy projects many years. He joined JPL in 1961 after working eight years in the ceramics industry and two years at North American Aviation. **WOLFGANG H. STEURER (M)**, a member of JPL's research team on the utilization of space resources, received a Ph.D. in 1940 at the Univ. of Stuttgart, Germany. During WW II he was in charge of the Materials Laboratory at the German rocket center Peenemunde. Upon coming to this country with the Von Braun team in 1945, he served on various space programs of the Army Missile Command at Fort Bliss, Tex., and Huntsville, Ala. He joined the Convair Div. of General Dynamics in 1958 and JPL in 1977. **ROBERT H. FRISBEE**, a senior engineer in JPL's Propulsion Systems Section, is the task manager of the Advanced Propulsion Concepts Study and a member of the JPL Space Station Trade Study Team. He received a Ph.D. in physical chemistry at the Univ. of California-Santa Barbara in 1978, and taught chemistry at California Polytechnic State Univ. before joining JPL in 1979. **ROSS JONES (M)**, a senior engineer in JPL's Power Systems Section, joined the laboratory in 1976 after receiving a M.S. in aeronautical and astronautical engineering from MIT. Previously he worked two years at Aerodyne Research, Inc., where he modeled infrared signatures of aircraft and rockets. At JPL, he has led a program to identify innovative concepts for future space power systems, and has worked on design studies of electric propulsion systems. He is a member of AIAA Electric Propulsion TC.

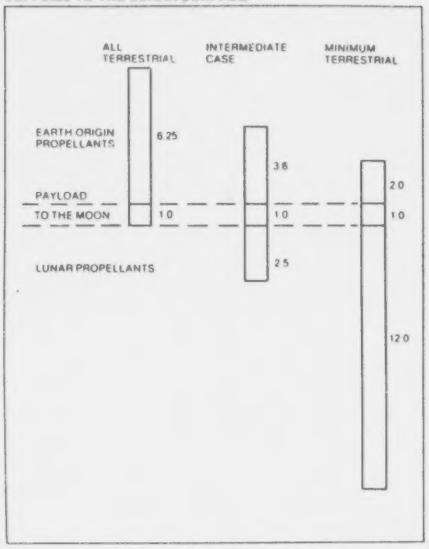
Products from extraterrestrial materials can play a major role in future space operations within the useful lifetime of our first major space station, now in the planning stage. This will not require the dramatic new space undertakings assumed in some studies,[1-3] but rather a moderate program of government and commercial use of space.

Extraterrestrial products such as oxygen can reduce the need for costly, energy-intensive launches from Earth. *It takes seven times more energy to get one kilogram from the Earth's surface to low Earth orbit (LEO) than it does to move one kilogram from the Moon's surface to LEO* (with aerobraking for LEO entry). These facts have led many investigators to study and propose lunar, asteroidal, and Martian materials for space operations.[4,5]

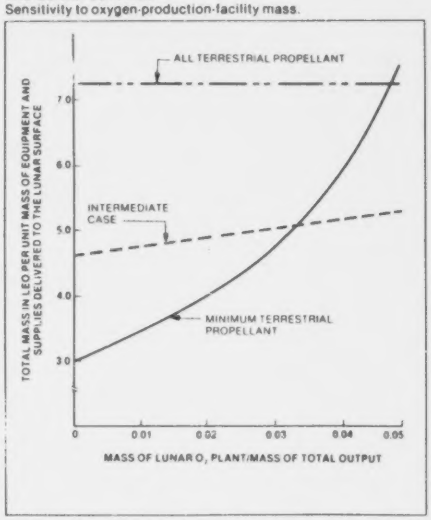
Production, transportation, and use of extraterrestrial materials of course will require equipment and supplies that must be launched from Earth. In fact, the mass of such equipment and supplies represents one of the major constraints on the use of extraterrestrial materials. Analysis has shown what the margin of advantage of extraterrestrial materials might be; has defined the limits on manufacturing and power facilities and on expendables; has set constraints on manned and unmanned operations for maintenance and repair; and has established a basis to evaluate the needs for, and possible impact of, new or improved technology. Rigorous mathematical treatment of this picture is beyond the article's scope but will be reported elsewhere. Here we examine engineering practicality. In what follows we normalize all masses to LEO for comparison to launch systems and space operations.

We look first at the transport of processing equipment from LEO to the lunar surface and of lunar products to LEO and GEO (geosynchronous orbit). We will emphasize conventional chemical propulsion using technology and hardware that can be expected to be in place for LEO to GEO orbit transfer in *less than two decades*. Aerobraking, used here for all cases of chemical propulsion for return to

F-1 SCENARIOS FOR TRANSPORTING EQUIPMENT AND SUPPLIES TO THE LUNAR SURFACE



F-2 TRANSPORTATION OF EQUIPMENT AND SUPPLIES TO THE LUNAR SURFACE
Sensitivity to oxygen-production-facility mass.



LEO, proves necessary for positive payoffs. This technique is already moving toward development for reusable orbit-transfer vehicles (OTVs) for LEO-to-GEO traffic.

Scenarios (F-1) describe transporting equipment or supplies from LEO to the lunar surface to establish, expand, or operate a production facility for three different cases: (1) all O_2 and H_2 propellants are brought from Earth. (2) All hydrogen and some oxygen is brought from Earth; some oxygen is produced on the Moon. (3) Hydrogen is brought from Earth; all oxygen is produced on the Moon.

As expected, the relative advantage of each depends on the "difficulty" of obtaining the lunar oxygen. For the three scenarios, F-2 shows the relation of the O_2 factory to transportation (mass) demands. The "minimum terrestrial" case, using large quantities of lunar-produced O_2, clearly looks best if the oxygen-production facility's mass per unit product can be small. It becomes less attractive rapidly as the facility mass increases. Using some terrestrial oxygen, as in F-2's intermediate case, lowers the sensitivity to the mass of the lunar factory.

T-1 describes several scenarios for transporting lunar products to LEO using conventional LO_2/LH_2 propulsion and aerobraking at LEO. Cases 1, 2, 3, and 5 use the baseline OTV and LTV systems. Case 4 is intended to illustrate limits that might be approached with major improvements in chemical propulsion.

Supplying all of the propellant from Earth (Case 1), keeps deliverable lunar payload less than the mass of the terrestrial propellant required to make the delivery (i.e., payload ratio less than 1.0). Unless future work identifies a lunar product which is somehow superior to its terrestrial competition, there will be no advantage from lunar products under these conditions.

Case 2, using all terrestrial H_2, terrestrial O_2 for return of the OTV to LLO, and lunar O_2 for the rest, shows some potential benefit for lunar products.

The baseline case (Case 3) assumes all terrestrial H_2 and all lunar O_2. It uses the least terrestrial propellant and produces the maximum payload ratio using the baseline transfer vehicles.

Improvement in performance (I_{sp}) and tare weight of the systems (both possible) would improve the margin of benefit from the use of extraterrestrial materials. Case 4 asssumes a zero dry mass of the OTV and LTV and thus represents a limit case for major chemical propulsion improvements. The difference is important but not revolutionary in terms of extraterrestrial materials and their utility.

Finally, Case 5 shows the effect of finding quantities of extractable H_2 or other fuel on the

T-1 LUNAR-TO-LEO TRANSPORTATION EXAMPLES

Case	Conditions	Propellants: Terrestrial O_2	Propellants: Terrestrial H_2	Propellants: Lunar O_2	Propellants: Lunar H_2[a]	Lunar payload to LEO	Payload ratio[b]
1	Baseline OTV—all terrestrial propellant[c]	321[c]	53.1	0	0	66.9	0.18
2	Baseline OTV and LTV; combined terrestrial and lunar O_2.	26.7	17.9	80.5	0	66.9	1.50
3	Baseline OTV and LTV; minimum terrestrial propellant.	0	17.9	107.2	0	40.2	2.25
4	Limit case; zero-dry-mass OTV and LTV	0	13.8	82.7	0	62.7	4.54
5	Assume lunar H_2 available[a]	0	0	89.8	14.9	54.1	∞

[a] Lunar H_2 has been postulated,[7] but not confirmed; results shown for illustration only.
[b] Payload ratio is defined as tons of payload delivered (from the lunar surface to LEO) per ton of terrestrial-origin propellant required in LEO to make the delivery.
[c] Requires multiple OTV trips and staging in LLO.

T-2 MASS OF FACILITIES ESTIMATED FOR PRODUCING O_2 ON THE MOON

In tons.

Process efficiency (product mass/input mass)	0.1		0.2		0.4	
Capacity, tons of product/yr	100	500	100	500	100	500
Processing plant and support

Total facility mass						
All electric power	61.4	282	35.2	153	21.5	86
50/50 electric/thermal	41.4	182	25.2	103	16.5	61

[a] Solar to electric at 5 kg/kW$_e$. Solar to thermal at 1 kg/kWh.

Moon. Watson et al have described a model for water-ice in permanently shadowed craters at the lunar poles,[7] but there is no concrete evidence for or against this model. The presence of a usable fuel would profoundly affect the entire program for exploring and utilizing space. The importance of volatiles has been discussed in detail.[8] A future *A/A* article will describe missions to seek usable fuel.

Several other options have been examined at varying levels of detail for transporting lunar products to LEO and GEO including electromagnetic launchers (e.g., rail gun and mass driver), electric propulsion, solar sails, and nuclear propulsion. An electric-propulsion OTV using lunar O_2 as propellant and combined with baseline chemical LTV can yield a payload ratio of ~8, but since the round trip time is ~200 days and the OTV power-supply mass is significant, the real advantage is less than 8. The same electric OTV combined with an electromagnetic launcher for the lunar surface to LLO produces an infinite payload ratio. However, the electromagnetic launcher and nuclear-propulsion technologies are not expected to be well enough established for application in the near future.

Products made using necessarily simple and automated space-production facilities will probably differ from what we make using complex industrial machinery on Earth. Relative function or performance thus need attention. In fact, it is useful to define breakeven performance for potential products.

We can define performance ratio as "how good" the extraterrestrial product is relative to its terrestrial competition for a particular job or function. Using just the quantities of terrestrial propellant for transport of products from the Moon to LEO from T-1, and assuming other factors related to extraterrestrial production to be minor, we can determine minimum breakeven performance ratios. For the baseline chemical-propulsion case (Case 3 in T-1) slightly more than 2 tons of lunar product can be returned to LEO for every ton of terrestrial-origin propellant. To just break even, the ~2 tons of extraterrestrial product must be equal in performance to Earth-origin competition with a mass of 1 ton that could be launched in lieu of the propellant. With conventional propulsion, therefore, the minimum performance ratio just to break even, for lunar products for LEO, will be ~0.5. Even with the limit case of zero dry mass transport vehicles, the break-even ratio is ~0.25. When the effects of other factors related to the production and transport of extraterrestrial products are considered, the break-even performance ratio increases.

In considering metallic components, we note a typical factor of 2× or greater difference between the tensile strength of unalloyed metals and their structural alloy counterparts and another factor of 2× to 6× between the non-heat-treated and heat-treated condition. Obviously, alloying, heat treating, and final machining are possible on the Moon, but each operation adds to the mass of the production and power-generation facilities. Given these mass-adding factors and the minimum breakeven performance ratio of 1/4 to 1/2 (even considering other factors insignificant), parts made from lunar-derived metals should not prove attractive for use in LEO, at least as an early product.

Similarly, it is unlikely that parts made from lunar-surface materials—"lunar bricks"—can meet the minimum performance ratio for structural use.

38-036 O - 84 - 45

They might meet the requirements of radiation shielding or some thermal or electrical insulation.

Delivering lunar products to GEO brings in different specifics than for delivery to LEO, but the net effects on candidate products are similar. To deliver 1 ton of lunar product to GEO takes 1 ton of terrestrial propellant in LEO. However, delivery of terrestrial products to GEO requires the mass of the terrestrial competition plus 3 to 4 tons of terrestrial propellant in LEO. Therefore, the effective payload ratio is 4 or 5 and the minimum break-even performance ratio for lunar products for GEO is 1/4 to 1/5. Although this improves the margin for extraterrestrial materials, it does not make enough difference to significantly modify the general constraints for LEO.

Consider next some limits on the mass of production and power-generation facilities and on expendables. For simplicity, assume that lunar oxygen will be the product delivered as well as a propellant for the transfer vehicles.

F-3 shows "return on investment" for two of the T-2 cases. The curves show tons of extraterrestrial product (O_2) delivered to LEO per ton of total Earth-origin equipment, supplies, and propellants required to produce and deliver the product, as a function of the mass of production facilities and supplies to the Moon. The two cases assume all terrestrial propellant for the transportation of processing equipment from LEO to the lunar surface (see F-2). The other processing-equipment transportation scenarios (not plotted) extend the breakeven points, but only by ~0.01.

For the baseline transport case, all the potential advantage of lunar oxygen disappears if production and power facility, supplies, and expendables exceed ~2% of the total (life-cycle) product mass. Even with the limit case, benefit disappears at ~5%.

Mass of production and power-generation facilities has been estimated for making O_2 on the Moon for a range of process efficiencies, plant capacities, facility lifetimes, and power-supply assumptions. T-2 and F-4 summarize results. Note that the more optimistic cases (high-capacity, high-efficiency, etc.) fall in a range of potential benefit (see lower curve of F-3) and that all high-efficiency cases fall within the range of potential advantage as defined by the upper curve in F-3.

Process efficiency obviously affects energy consumption and the resulting mass of the generating facility. *Thus a high priority for current research should be given to gathering experimental and analytical information that will allow reliable estimates of energy efficiency.*

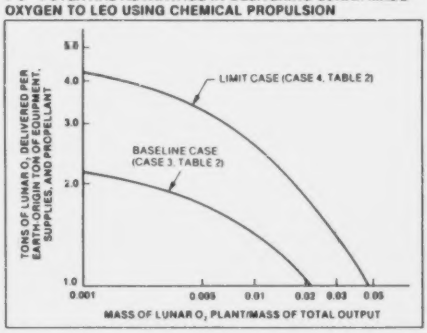
The mass associated with production and power generation will be "amortized" over the total O_2 produced during the facilities' operational lives.

When we compare estimates of facility mass (F-4) with the limits of the facilities plus supplies (F-3) we see that the expendable or consumable supplies must be held to a very small fraction of the product mass—about 1% or less. In molten-silicate electrolysis experiments, Kesterke used 2/3 to 3/4 by weight flux and was unable to recover or recycle any of it.[9] At the lower level, the mixture contained ~4 kg flux per kg of oxygen. A recycling recovery of ~99.75% would be necessary to keep consumption down to 1% of product mass. Such a level would be difficult with multistage terrestrial facilities, and unlikely with the simple facilities that will be practical on the Moon.[10] Thus, the use of expendable items such as fluxes, process aids, and sacrificial electrodes—even in small quantities—appears to be impractical. Recognition of this limitation led to our recent demonstration at JPL of the production of metals and oxygen by the electrolysis of molten (simulated lunar) magma without the use of flux or sacrificial electrodes.[11]

Similarly, lunar products that require wet chemical processes seem impractical for use in LEO, since a large mass of reagents and equipment would have to be imported from Earth. Also, they would probably require too much recycling of reagents.

The above discussion concerns oxygen for both transport propellant and product. Some more general conclusions are possible. Typically, "high technology" products that involve many separate process steps—electronic devices and conventional silicon photovoltaics—require elaborate processing facilities with a mass much greater than 1-2% of the mass of product made over the plant's lifetime. Such "high-technology" products made from lunar

F-3 POTENTIAL ADVANTAGE IN DELIVERING LUNAR-MADE OXYGEN TO LEO USING CHEMICAL PROPULSION



materials do not appear to be viable for use in LEO. However, their potential for lunar use, and possibly even for GEO, cannot be ruled out with the current state of knowledge.

Crew operations will probably be needed only for site surveys, installation and startup of facilities, and infrequent visits for nonroutine maintenance. Routine operation and maintenance will be handled by combined automation and remote control.

The mass in LEO required for crew operations in relation to the mass of a potential extraterrestrial product will be an important consideration.

The Apollo system provides a useful reference. It was capable of delivering two people, with equipment and supplies, to the Moon and returning them to Earth. It started with a mass of more than 100 tons in LEO.[12]

To illustrate the relationships, assume deliveries of lunar O_2 to LEO for satellite orbit raising at the rate of 100 tons per year with a 2:1 advantage, that is, 100 tons of lunar O_2 delivered for every 50 tons of terrestrial-origin equipment and supplies put into LEO for lunar-product production and transport. Under these circumstances, a single Apollo-type manned mission every two years for operation or maintenance would more than eliminate the entire advantage of the use of extraterrestrial O_2. For a "market" of 500 tons per year and the margin of 2:1, occasional Apollo-scale maintenance missions might be acceptable.

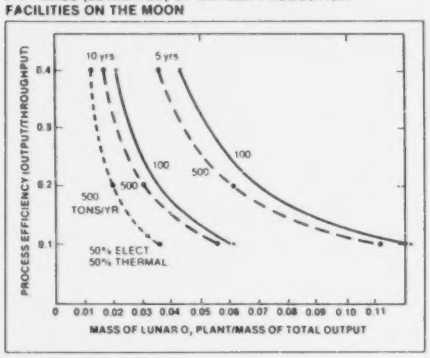
At the level of 100 tons of lunar O_2 assumed above, one or two manned missions for site surveys and installation and startup would be acceptable if the operation lasted about 10 years or more.

As an example of the other extreme, consider lunar O_2 delivered to LEO for life support on a manned space station. At 0.84 kg (1.84 lb) per person-day (~300 kg per person-year) a station with a crew of 20 would require only 6 tons per year.[13] Even if lunar O_2 could be produced and delivered at 2:1 advantage, more than 30 years would be needed to recover the investment of a single Apollo-type mission for exploration and startup. Obviously, using the lunar source for such a small supply will be practical only in combination with larger quantities of O_2 expected to be required for orbit raising.

In conclusion, we might summarize results in terms of the two key factors: origin of the material and point of use.

The principal effort has been on lunar materials for use in LEO, using chemical propulsion with aerobraking for transport. Other propulsion options have been examined with less rigor, but in sufficient depth to reach the following conclusions concerning lunar products for use in LEO.

F-4 MASS (ESTIMATED) OF OXYGEN-PRODUCTION FACILITIES ON THE MOON



- To make the use of any lunar produced material practical, lunar oxygen or some unconventional form of propulsion, such as an electromagnetic launcher, will be needed for its transport.
- Products with performance directly or nearly proportional to mass—O_2 propellant and lunar products for radiation shielding—can have an advantage over terrestrial competition.
- Structural metal-alloy parts will probably not be practical, and can be so only if their performance closely approaches terrestrial competition.
- Components made from unrefined or partially refined lunar-surface material such as "lunar bricks," primarily for structural purposes, are *very unlikely* to be competitive.
- Products which require production facilities and processing aids or reagents on the Moon of more than 1-3% of the life-cycle product mass are *very unlikely* to be competitive. This would appear to preclude consideration of conventional electronics or silicon photovoltaics, which require extensive facilities, and wet chemical processes, unless they entail little facility mass and their reagent recovery and recycling approaches 100%.

As to lunar products for use in GEO, they have somewhat greater advantage over terrestrial competition than lunar products delivered to LEO, but not enough to change the conclusions regarding lunar products for LEO.

Analyses similar to these have been completed for other origins and points of use of extraterrestrial materials, with the following tentative conclusions.

Asteroidal products for LEO:

- Transport of products from some asteroids requires less energy than from the Moon, but the differences using conventional chemical propulsion are not sufficient to reach conclusions different

from those regarding lunar products for LEO.

- Because asteroids have very low escape velocity, near-term electromagnetic launcher technology may be practical for bringing asteroid material to LEO. But its applicability, use, and constraints are too uncertain for definitive assessment at this time.

Lunar materials for lunar-surface use:

- Lunar materials can have an advantage over terrestrial competition for lunar use, even with a performance disadvantage of the order of 100. Even such as structural "crude" metal-alloy parts and "lunar bricks" may be advantageous.

The analyses described here indicate that high-performance lunar products—O_2 and radiation shielding—probably can be produced by relatively simple equipment and should be commercially attractive for use in LEO or GEO as soon as these sites show a market for quantities in the range of 10^2-10^3 metric tons per year. Experts see this as possible by the turn of the century—not much more than a well-conceived development cycle away.

MATERIALS ENGINEERING IN THE SKY

By John C. Bittence, Senior Editor

Processing in space could create a whole new world of materials

By John C. Bittence, Senior Editor

Some time, probably before 1982, the Space Shuttle will deliver the first scientific payload into orbit. Once in place, the Skylab will begin humming as dozens of experiments, scientific and military, public and private, are activated. Somewhere deep within the Shuttle, in a five-cubic-foot container, a movie camera will whir while a small cloud of moisture begins to crystallize into a snowflake. The first of hundreds of materials-science experiments destined for Space Shuttle delivery and pickup is taking place. It's a study to observe the growth of a snowflake under gravity-free conditions.

In latet flights, scientists hope to produce superpure glass, inexpensive solar cells, and a host of metallic alloys that don't even exist on earth. By 1984, between 100 and 120 materials experiments per year will be conducted in space. Eventually, these experiments may turn into full-fledged manufacturing operations to produce earth-bound products. Ultimately -- though certainly not in the near future -- raw materials for these operations may be mined and imported from the moon.

The attraction of 0g

Why will we go thousands of miles above the earth to process materials and make parts? Primarily, because the space environment offers a combination of conditions that are difficult, if not impossible, to duplicate on earth. First of all, space offers a cheap solar-energy supply. In addition, near-perfect vacuum (down to 10^{-14} torr) is right at hand, temperature extremes between −200 and +200°F (−130 and +93°C) are readily available, and the environment is always free from atmospheric-related corrosives and impurities.

The most valuable condition in space, however, is the almost total absence of gravitational force. Although a trace, or microgravity (up to $10g^{-6}$), is always present, this value is practically zero for most materials applications.

Near-zero gravity does not result from the satellite being beyond the earth's pull, because it is not. Although gravitational forces in orbit are much less, the earth's pull on a satellite is still significant. Rather, low gravity, or weightlessness, results from the balance of forces that keep the satellite and its contents in orbit. Microgravitational forces arise when this delicate balance is upset by simple movements of the craft caused by orbit corrections, equipment operations, or even motion of the occupants. "We are always dealing with microgravity, never zero gravity," points out Frank J. Jelinek, associate section manager, Battelle-Columbus Laboratories. "But for most purposes, we regard it as 'zero.' "

Weightless conditions in orbit may be a bonanza to metals researchers. At "zero g," everything floats, so molten materials can be solidified in vacuum without ever contacting a container wall. In addition, at zero g, mixtures of light and heavy substances stay mixed. Materials solidified at zero g are homogeneous; there's no settling out of more dense constituents, and no turbulence during freezing.

One of the first phenomena researchers want to study in space is the solidification of immiscible metals — metals that normally don't form alloys on earth because one is pulled out of solution by gravity before the molten material solidifies. Over 500 such binary metallic systems with miscibility gaps on earth have been identified. Scientists are eager to determine whether any of these materials are superconductors, superplastic, or possess any unusual magnetic or electrical properties when solidified in zero gravity. "The potential here is tremendous," observes Battelle's Alan J. Markworth, a physicist anxious to get the Space Shuttle under way. "Although we've primarily been studying the aluminum-indium system (because it's easy to work with), there are hundreds of alloys that could develop into something useful," Markworth adds.

Miracles from immiscibles

Battelle has been studying miscibility-gap metals since 1973, but only recently have they been able to test out their theories under low-gravity conditions. Alloys of Al-40In and Al-70In, cast during a few precious seconds of near-zero gravity during the free-fall trajectory portion of SPAR II rocket flights from Marshall Space Flight Center, yielded some suprising results.

First, in the absence of gravity, lesser known physical phenomena become extremely important. Surface tension, for example, plays only a minor role in metal casting and solidification on earth, where gravity is the dominant force. In space, however, in the absence of gravity, surface tension plays an active part.

In addition, thermal viscosity and thermal conductivity in the cooling

metal can become bothersome. In one Battelle rocket experiment reported by Markworth, thermal gradients, rather than gravity, induced segregation — and immiscibility — in an Al-In casting. One theory suggests that thermocapillary flow (the Marangoni Effect) is the culprit leading to segregation in the absence of gravity.

Gravity-driven convection currents also are absent from the molten metal in space. The result is a finer microstructure than is possible on earth. In some cases, unexpected and unidentified phases have turned up in low-gravity castings. Paradoxically, and totally opposite from earth-bound metal behavior, slowly cooled metal in space has a finer microstructure than rapidly cooled samples.

Scientists admit that they are just beginning to understand the behavior of immiscible metals. In fact, most of the experiments to date have raised more questions than answers. Ultimately, scientists agree that space experimentation will contribute substantially to our technical understanding of materials behavior, including solidification dynamics, vaporization and condensation, and diffusion.

Specific metallurgical achievements that scientists hope will result from zero-gravity experimentation include manufacture of superhigh-strength magnets in space for use on earth, production of extremely strong, fine-grained welds between metals not weldable on earth, continuous casting of dispersion-strengthened metals, melt-

A pinch of basalt

Although it's still a generation away, researchers are already predicting the day when we will be mining the moon for raw materials. Most likely, these materials will be delivered to orbiting factories that manufacture huge structures in space. A 13-mi^3 satellite to collect solar power for the earth, for instance, could be made of 90% lunar materials.

Lunar mining is attractive because it takes 22 times more energy to send material into orbit from the earth than from the moon. In addition, a wealth of metals and minerals are available right on the surface of the moon, as the table shows.

Notably absent from the lunar crust is hydrogen, thus making the production of water impossible. Moon mining and beneficiation will have to rely on anhydrous techniques. Also, because of low gravity and lack of an earth-like atmosphere, mining will probably be unmanned.

Materials the moon holds in store for us

Element	Earth rank	Earth composition, ppm by weight	Moon composition, ppm by weight	
			Highlands	Mare
Oxygen	1	466,000	417,000	446,000
Silicon	2	277,000	212,000	210,000
Aluminum	3	81,300	69,700	133,000
Iron	4	50,000	132,000	48,700
Calcium	5	36,300	78,800	106,800
Sodium	6	28,300	2900	3100
Potassium	7	25,900	1100	800
Magnesium	8	20,900	57,600	45,500
Titanium	9	4400	31,000	3100
Hydrogen	10	1400	54	36
Phosphorous	11	1050	660	500
Manganese	12	950	1700	675
Carbon	17	200	100	100

ing and casting of highly reactive metals without the need for crucibles or molds, production of ultrapure metals, and the development of new families of intermetallics and immiscible alloys.

Superfibers, superglass

Engineering fibers on earth made from glass, carbon, or ceramics have only a fraction of their theoretical strength. Surface irregularities, grain boundaries, and crystalline defects, all introduced during manufacture, reduce fiber strength and ductility. Space-produced fibers, on the other hand, probably will more closely approach theoretical properties.

Techniques have been proposed for growing high-strength, monocrystalline fibers, or whiskers, of materials such as silicon carbide to be used as reinforcement for metals and composites. In an early, rocket-borne experiment with silver, whisker-strengthened with 5% SiC, bending strength was improved by 20% and deflection under load improved by a factor of seven.

Even more impressive, however, are predictions for improvements in optical glass and solar silicon made in space. Some of the first materials that will be studied in the Space Shuttle are ultrapure laser glass and fibers for optical wave guides.

Battelle has developed a new technique for producing glass and glass-ceramics that is especially adaptable to the special conditions of space. Called the Sol-Gel process, the scheme requires both the zero g and high vacuum of outer space (ME 7/80).

In the realm of glass and ceramics, researchers expect another materials bonanza. "Magnetic" glass ($FeBO_3$, containing 70% ferromagnetic iron) has great potential for magneto-optical devices. Unfortunately, this unusual material cannot be made on earth in a form suitable for these devices. It can, however, be produced by containerless melting in space.

Glass products with dispersion, refractive, and other properties unavailable in earth-made materials possibly can be created in space. For instance, lasers can be made more efficient by increasing the calcium content of the Nd-Ca-Li-Al silicate glass optics. Unfortunately, this can't be done on earth, since contact by calcium with the container walls during melting causes devitrification. In space, however, high-efficiency laser optics can be made by containerless melting. According to an Owens-Illinois study, improvement in laser efficiency should be well worth the cost of processing in space.

Similar predictions are made for space-processed solar silicon and various semiconductor materials such as Ga-As. According to some estimates, high yield from space-processed semiconductor materials will easily offset the high costs of space processing. The added benefits of space processing will stem from improved reliability of space-made semiconductors.

Typical glass and ceramic products

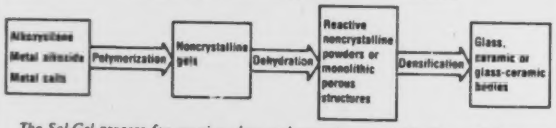
The economics of space processing

NASA calls it their "getaway special." For $10,000, anyone can tuck a 200-lb payload into the bowls of the Space Shuttle for delivery — along with the rest of the cargo — into orbit around the earth. An additional $10,000 of the cost is government subsidized, so the total cost for a trip into space is about $100/lb, or 100 times less than the cost in 1960. By 1990, a trip into orbit should cost $25/lb — still an expensive ride.

On the other hand, efficiency of solar-energy generators can be at least doubled if critical silicon cells were made in microgravity space. The rejection rate for certain earth-grown, high-purity semiconductor wafers can be reduced from present-day high rates to practically "zero" when they are grown in orbit. And an ultrapure version of a biological material called collagen produced in space would be almost priceless for medical treatment of burns, replacing blood vessels, and producing artificial corneas.

The cost benefits of producing certain materials in space, especially in minifactories that can be refurbished and returned to orbit, are indeed worth the steep transportation costs.

Sol-gel process for glass and ceramics



The Sol-Gel process for growing glass and ceramic parts is ideally suited for space production of optical waveguides. According to Battelle, noncrystalline gels can be produced on earth and sent into orbit for melting. An accoustical positioning device would suspend the material during dehydration and densification to prevent contamination. Glass bodies would then be returned to earth to be drawn into low-loss waveguide fibers.

that scientists hope to develop from space experimentation include "selective-wavelength" optics, holographic storage devices, better integrated circuits, ferroelectrics, and high-performance lenses and mirrors.

MPS ready to fly

In 1978, NASA recognized the potential benefits from materials experimentation in space by awarding the Materials Processing in Space program (MPS) to TRW Defense and Space Systems Group. The assignment was to develop a new facility for materials R&D in space with the ultimate possibility of performing commercial work in orbit. According to NASA, the MPS facility will be used to "conduct applied research in fluids technology and materials solidification relating to electronic materials, metals, ceramics, glass and chemicals." Manufacturing processes outlined as being particularly adaptable to the space environment include melting and casting, vapor deposition and powder metallurgy.

Two MPS payloads emerged. The first, the manned facility for fluids experiments and vapor crystal growth, will be installed in one of the Spacelabs. The second unit, a pallet-mounted experimentation system, will ride in the Shuttle's cargo bay. This unit is designed to perform more than two dozen solidification experiments in a high-temperature furnace by preprogrammed control.

By about 1984, the NASA power module for free-flying orbital missions should be ready, and TRW's MPS program will be ready for its next step — launching of the Materials Experimentation Carrier (MEC) which will link up with the power module for missions of up to 120 days. By 1987, MEC will become a manned, fully serviceable, continuously orbiting facility, called the Materials Experimental Module, MEM-1. It will be used for advanced R&D materials and pilot-plant production. By 1990, MEM-1 will be replaced by MEM-2, whose specific design and mission are yet to be established.

The mine in the moon

Some researchers envision the day when a facility similar to the MEMs would be supplied with raw material from the moon, or perhaps from nearby mineral-rich asteroids, although beneficiation of these elements will require novel technology. Unlike earth-bound beneficiation, which relies on water, acids, bases and an atmosphere, moon processing of raw materials probably would be based on electrostatic beneficiation powered by solar energy. Because of low gravity and lack of an earth-like atmosphere, mining on the moon would probably be totally automated.

The rationale for moon mining stems from the lower escape velocity — approximately one-fifth that of the earth — required to remove a mass of material from the surface. A NASA-funded study by General Dynamics, Convair Div., proposes that materials be catapulted from the moon's surface and captured by space "garbage trucks" for batch delivery to the production facility for processing. Ultimately, NASA would consider building entire space stations in space, deriving 90% of the raw material for construction from the

moon. Lunar material would cut costs of in-orbit construction by about one-third.

When will all this take place? "These things are *all* conceivable," points out Battelle's Jelinek. "Probably by the time your children and my children are senior citizens, they will be a reality." General Dynamics researchers agree, observing that current and projected capabilities to produce solar energy sufficient to carry out lunar mining will not even exist by 1990.

A National Research Council committee, studying NASA's original MPS proposal in 1978, was even more cautious. "The committee has not discovered any examples of economically justifiable processes for producing materials in space," they reported. "When gravity has an adverse effect on a process, stratagems for dealing with it can usually be found on earth that are much easier and less expensive than recourse to space flight."

On the other hand, Europe, Japan, and the USSR have given top priority to materials science experimentation in space. In a General Accounting Office review last winter of space-processing programs proposed or carried out by NASA so far, the U.S. Congress was taken to task for its low funding and support of materials experimentation in space. In fact, according to GAO, foreigners could easily assume the lead in materials science in space, since materials experiments in early Shuttle/Spacelab missions will be predominantly performed by other nations.

The European Space Agency, ESA, currently developing the first Spacelabs in cooperation with a consortium of European businesses, has selected materials processing as one of the two disciplines to be included in the first flight. ESA has a list of about 120 materials science experiments they would like to propose for the first and subsequent Spacelabs.

Begins with a snowflake

From manned factories in orbit to unmanned strip mining of the moon . . . it will all start by growing a tiny snowflake aboard the Space Shuttle. The snowflake will be grown because two Japanese 16-year-olds suggested the experiment, and Battelle was commissioned to include it in one of the first of two Space-Shuttle payloads for it which it purchased flight options. The teenagers won a contest sponsored by a Tokyo newspaper, *Asahi Shimbun*, out of more than 16,000 entries proposing ideas for research experiments that could be conducted aboard the NASA shuttle.

Toshio Ogawa and Yasuhiko Oda wanted to see whether snowflakes grown in the weightlessness of space differed from those grown under gravitational influence of the earth. Battelle's Alan Markworth liked the idea; he's anxious to determine whether the basic platelet flake will grow in three dimensions. Differences in morphology between earth and space-grown flakes will be evaluated for scientific significance. "Although," concedes Markworth, "a lead-off experiment such as this will have a lot of public appeal, too. Especially in Japan." Cost of the snowflake project: $100,000, which includes a $10,000 ticket for the ride in the Shuttle. The sole product of the experiment will be a length of four-color film. ■

REPORT BY THE

Comptroller General

OF THE UNITED STATES

Effects On Users Of Commercializing Landsat And The Weather Satellites

In March 1983, the administration proposed to transfer the National Oceanic and Atmospheric Administration's satellites--a land-observing satellite, called Landsat, and the weather satellites--to the private sector. This report discusses how these satellites are used worldwide and how their commercial operation might affect users.

In November 1983, the Congress enacted legislation to prevent the sale of the weather satellites; the administration is proceeding with its efforts to commercialize Landsat. In considering legislation to authorize a sale, the Congress should consider whether the sales terms proposed by the administration adequately protect the interests of Landsat users in the United States and abroad.

GAO/RCED-84-93
FEBRUARY 24, 1984

Request for copies of GAO reports should be sent to:

U.S. General Accounting Office
Document Handling and Information
Services Facility
P.O. Box 6015
Gaithersburg, Md. 20760

Telephone (202) 275-6241

The first five copies of individual reports are free of charge. Additional copies of bound audit reports are $3.25 each. Additional copies of unbound report (i.e., letter reports) and most other publications are $1.00 each. There will be a 25% discount on all orders for 100 or more copies mailed to a single address. Sales orders must be prepaid on a cash, check, or money order basis. Check should be made out to the "Superintendent of Documents".

COMPTROLLER GENERAL OF THE UNITED STATES
WASHINGTON D.C. 20548

B-214057

The Honorable Jack Brooks
Chairman, Subcommittee on Legislation
and National Security
Committee on Government Operations
House of Representatives

The Honorable Charles McC. Mathias
United States Senate

The Honorable John C. Stennis
United States Senate

The Honorable Edward Zorinsky
United States Senate

This report discusses how the National Oceanic and Atmospheric Administration's remote sensing satellites--Landsat and the weather satellites--are used by federal agencies, other U.S. organizations, and foreign governments and how users might be affected by the commercialization of these satellites. It also outlines issues regarding the commercialization of Landsat for consideration by the Congress as it takes up legislation to authorize its sale. As requested by your offices, the report presents the information we developed on the weather satellites, even though their sale has been prevented by recent congressional action. Our classified report to you entitled National Security Implications of Commercializing Landsat and Weather Satellites (GAO/C-RCED-84-1, Feb. 1, 1984) discusses commercialization in relation to national security issues.

As arranged with your offices, unless you publicly announce its contents earlier, we plan no further distribution of this report until 30 days from the date of the report. At that time we will send copies to the appropriate House and Senate committees, the heads of departments and agencies whose programs we discuss, Members of Congress, and other interested parties.

Milton J. Socolar

Acting Comptroller General
of the United States

COMPTROLLER GENERAL'S REPORT

EFFECTS ON USERS OF COMMERCIALIZING LANDSAT AND THE WEATHER SATELLITES

D I G E S T

The Department of Commerce's National Oceanic and Atmospheric Administration operates two remote sensing satellite systems--the weather satellites and Landsat--which produce data with worldwide uses. In March 1983, the administration announced its decision to transfer these satellites to private enterprise and rely on the private sector in the future for the data these systems supply. The administration wants to commercialize Landsat because it believes that the private sector can develop a market for Landsat data better than the federal government and can help the United States retain its international lead in this technology. Inasmuch as the Landsat activities are not presently economically self-sustaining, commercialization of the weather satellites was proposed so the private satellite owner would be assured of a source of revenue while the Landsat market was being developed.

The Chairman, Subcommittee on Legislation and National Security, House Committee on Government Operations, and Senators Mathias, Stennis, and Zorinsky, asked GAO to examine several aspects of the proposed sale, including

--its effect on the national security of the United States,

--the uses which federal agencies have or expect to have for satellite data,

--the effect of the sale on nonfederal United States and foreign government users, and

--conditions which could be included in the contract transferring the satellites to the private sector.

The national security aspects of the proposed sale are discussed in GAO's classified report entitled National Security Implications of Commercializing Landsat and Weather Satellites (GAO/C-RCED-84-1, Feb. 1, 1984). Recent congressional action has prevented the sale of the weather satellites, but the information GAO developed on these satellites is included in

this report at the request of the Members of Congress who asked for the GAO review. (See pp. 3 to 5, and 27 to 42.)

LANDSAT USES

Since 1972, the United States has maintained in orbit a series of land sensing satellites called Landsats. The current Landsat is the fourth in the series. Landsat "senses" the earth's surface and sends the data back to earth in a form which can be processed into photographic images or computer-compatible tapes. Landsat data are used around the world to estimate and manage crop production; explore for minerals, including petroleum; make and revise maps; and accomplish other purposes. Landsat data are used in the United States by federal and state agencies, industrial and service businesses, and universities. Landsat is also used extensively by foreign governments which operate 10 ground stations to pick up Landsat signals. The federal government had spent, through March 1983, about $477 million to build, launch; and operate Landsat 4; to build a satellite to succeed Landsat 4; and for the Landsat ground system. The U.S. government charges Landsat users a fee designed to recover operating costs, but not building or launching costs. (See pp. 2 and 3.)

USER CONCERNS RAISED BY THE PROPOSAL TO COMMERCIALIZE LANDSAT

A change from government to commercial operation of Landsat could mean major changes for Landsat users. GAO discussed these possibilities with a sample of users, including representatives of 18 federal agencies, 16 other U.S. users, and 10 foreign countries. The views GAO obtained on commercialization were those of organization officials and may not represent the formal position of the organizations themselves. (See pp. 7 and 8.)

Federal and nonfederal domestic users of Landsat believed the present limited market for Landsat would not allow a private operator to make a profit at current prices. They were concerned that with monopolistic control over the supply of data, a private operator could increase prices and also reduce data quality. Both federal and nonfederal users believed that

a commercial operator would not perform sufficient research and development. (See pp. 11 and 12, and 23 to 25.)

Representatives of several nonfederal users recommended that commercialization of Landsat proceed in stages beginning with data distribution. These users said that a gradual turnover of the system to the private sector would improve the chance for successful commercial operation by allowing time for development of a profitable market. (See p. 25.)

Private companies which buy Landsat data from the government for analysis and resale--termed "value-added" companies--were concerned that a private operator would use its control over the source of data to drive them out of business. (See p. 23.)

Under federal operation, Landsat data have been broadcast directly from satellites to receiving stations operated by foreign governments. The United States has followed an equal access data distribution policy, making Landsat data available to all interested parties, including the country from which the data were sensed, at the same time and on the same terms.

Foreign governments were concerned that commercial operation of Landsat might change these data distribution arrangements. They were concerned that a private operator might, for commercial reasons, stop transmitting data to their ground stations--very often facilities in which they had invested considerable resources--or that the operator would increase prices to the point that they could no longer afford the data. Also, the foreign governments said that a private company might find it profitable to sell, for the exclusive use of outsiders, information on their countries' resources or activities, which would be harmful to their economic or national security interests. (See pp. 17 to 19.)

Although most federal and other U.S. Landsat users believed that commercialization could affect them adversely, some believed that private control of the satellites would help improve service and increase marketing of data. (See pp. 9 and 23.)

38-036 O - 84 - 46

HOW THE REQUEST FOR PROPOSALS ADDRESSES USER CONCERNS

Following the March 1983 announcement of the administration's decision to commercialize the satellites, the Department of Commerce set up a Source Evaluation Board to prepare requests for proposals. Requests for proposals were drafted for both Landsat and the weather satellites, but because the Congress enacted legislation in November 1983 to prohibit the sale of the weather satellites, only the Landsat request was issued. Responses to this request for proposals are due at the end of February 1984.

The Landsat request for proposals requires offerors to describe the type of land remote sensing system they would build to replace the current system and the operating and pricing policies they would follow. It also indicates that the government is willing to provide financial assistance to a private operator and invites offerors to state what form of financial assistance they would prefer. According to Source Evaluation Board officials, financial assistance is being considered because the current market for Landsat data is not strong enough to support a profitable operation. (See pp. 5 to 7.)

Complete information on the operating characteristics of a commercial land sensing system and the associated costs will not be known until a contract is agreed upon by the government and a private operator. However, the request for proposals does address many of the concerns raised by federal Landsat users. For example, the request for proposals requires a private operator to orbit a sensor which provides data at least equal to the current Landsat operational sensor. In addition, a prospective operator must describe methods for improving data coverage and timeliness and for ensuring that data quality is maintained. The request for proposals also states that the government plans to continue land remote sensing research and development.

However, the request for proposals satisfies fewer of the concerns raised by international and nonfederal Landsat users. For example, subject to U.S. government approval, the private operator could terminate broadcasts to foreign ground stations and change the

present federal data distribution policy by refusing to sell data to a country from which the data were sensed. A private operator might find these changes commercially advantageous. The request for proposals does not describe the criteria that the federal government would apply to requests by a private operator for these changes. But because Landsat will be a commercial venture, economic considerations may influence government policymaking to a greater extent than in the past. The private operator would also be permitted to enter the value-added industry. According to Source Evaluation Board officials, the request for proposals does not impose all the restrictions on a commercial operator that international and nonfederal U.S. users want, because the request is designed to encourage full commercial development of a land remote sensing system with a minimum of federal regulation. (See pp. 12, 13, 19, 20, and 25.)

MATTERS FOR CONSIDERATION BY THE CONGRESS

The administration plans to propose legislation to the Congress to authorize commercialization. The Congress may set out in this legislation requirements for commercial operation in addition to or different from those contained in the request for proposals.

In deliberating on this legislation, the Congress may wish to consider the following:

--Should a private Landsat operator be required, under terms and time frames specified by the Congress, to continue present arrangements for broadcasting data to foreign ground stations?

--Should a private operator be required to continue the traditional U.S. government policy of providing a sensed country with equal access to data obtained on its territories and activities?

--Should protection be provided to firms in the value-added business so that they can compete with the private Landsat operator? For example, the Landsat operator could be required to make data available to all value-added firms on the same terms and as soon as the data are ready for analysis by the operator itself.

--Should a step-by-step approach to commercialization, beginning with data distribution, be an alternative to control of the whole system. (See pp. 20, 25, and 26.)

Any legislation authorizing the commercialization of Landsat must balance the financial interests of the private operator against the concerns of Landsat users that unregulated commercial operations will adversely affect their interests. Potential private operators will in turn consider whether legislatively or administratively established terms and conditions make private Landsat operation economically attractive.

HOW THE CANCELLED PLAN TO COMMERCIALIZE THE WEATHER SATELLITES WOULD HAVE AFFECTED USERS

GAO discussed the proposed plan to commercialize the weather satellites, now cancelled because of congressional action, with officials of 7 federal agencies, 14 other U.S. users, and 11 foreign countries which use U.S. weather satellite data. Federal and domestic nonfederal weather satellite users wanted to avoid higher charges for weather data they now receive free or at low cost. They also wanted the current level of data and services to be maintained. Private companies that did value-added work on weather satellite data believed that entry of a private operator into their business would jeopardize their existence. Foreign users of weather satellites were concerned about charges for satellite data previously provided at no cost through programs such as the United Nations' weather information exchange system.

Although most federal and other U.S. satellite users said that commercialization could affect them adversely, some believed that private control of the satellites could help improve service and data marketing.

The unissued weather satellites request for proposals sought to ensure that, for the most part, commercial operation of weather satellites would not affect current users. The private operator would have been required to continue present services and supply the U.S. government with data and services to continue present international meteorological

cooperation. Users of the weather satellite communications services, however, might have faced price increases and the private operator would have been allowed to enter the value-added business. (See pp. 27 to 42.)

CHAPTER 1

INTRODUCTION

On March 8, 1983, the administration announced its decision to transfer the federal government's operational civil remote sensing satellites to the private sector. The satellite systems to be included in this transfer were Landsat (the land remote sensing satellite) and the weather satellites. Since the data produced by these satellites are used by numerous federal, international, and private organizations, the effect of any changes in the operation of Landsat and the weather satellites would be widespread. Questions were raised among all of these groups concerning the advisability of the transfer, the terms and conditions which should be included in the transfer, and the effect the transfer would have on users.

The Chairman, Subcommittee on Legislation and National Security, House Committee on Government Operations, and Senators Mathias, Stennis, and Zorinsky asked us to examine several aspects of the proposed transfer, including

--its effect on the national security of the United States,

--the uses which federal agencies have or expect to have for satellite data,

--the effect of the sale on nonfederal U.S. users and foreign government users, and

--possible conditions which could be included in the contract transferring the satellites to the private sector.

In November 1983, after the completion of our review, the Congress enacted Public Law 98-166 prohibiting the transfer of the weather satellites to the private sector. The requestors nevertheless asked us to report the information we had developed on the weather satellites as well as Landsat.

The national security aspects of the proposed sale are discussed in our classified report entitled National Security Implications of Commercializing Landsat and Weather Satellites (GAO/C-RCED-84-1, Feb. 1, 1984).[1] The remaining aspects of the proposed sale, including the reaction of federal, international, and private users of satellite data, are discussed in the following chapters.

---

[1]See also our earlier report entitled Costs and Uses of Remote Sensing Satellites (GAO/RCED-83-111, Mar. 4, 1983).

CHARACTERISTICS AND USES OF THE SATELLITE SYSTEMS

The United States currently has five civil operational remote sensing satellites in orbit--one land remote sensing satellite (Landsat) and four weather satellites. All of these satellites were developed by the National Aeronautics and Space Administration (NASA) and are operated by the Department of Commerce's National Oceanic and Atmospheric Administration (NOAA).

Landsat

The first Landsat was launched in 1972; three replacements have been placed in orbit since then. The present Landsat, Landsat 4, was launched in July 1982 but is malfunctioning. A replacement for Landsat 4 is scheduled to be launched in March 1984.

Landsat "senses" the earth's surface and sends the data back to earth in a form which can be processed into photographic images or computer-compatible tapes. Landsat 4 carries two instruments: the multispectral scanner and the thematic mapper.[2] The multispectral scanner, which was one of the instruments carried on the previous Landsats, is considered the operational sensor. The thematic mapper is a more advanced sensor but is considered experimental.

Data transmitted from Landsat are received by the Goddard Space Flight Center in Maryland and by 10 foreign ground stations which are operated under cooperative agreements with the U.S. government.[3] The data received at the Goddard Space Flight Center are transferred to the Department of the Interior's Earth Resources Observation Systems Data Center in South Dakota where they are processed, stored, and sold as photographic images or computer-compatible tapes.

Landsat data are used by numerous federal and state agencies, foreign countries, university researchers, private businesses, and individuals. The following table shows the percent of Landsat

---

[2]The multispectral scanner monitors materials on the earth's surface--water, crops, and forests for example--by measuring the light waves which they reflect. The thematic mapper is a more sophisticated sensor which monitors the earth's surface in greater detail than the multispectral scanner.

[3]In calendar year 1983, each of the following countries operated one ground station: Argentina, Australia, Brazil, Canada, India, Japan, South Africa, and Thailand. In addition, the European Space Agency operated two ground stations.

products sold at the Earth Resources Observation Systems Data Center to each of the user groups for fiscal year 1983.

FY 1983 Landsat Purchases From the Earth Resources Observation Systems Data Center

Customer	Products	Dollar
	----------Percent----------	
Federal government[a]	47	75
State/local government		
Academic	4	3
Industrial	10	9
Individual	3	1
Non-U.S.	34	11
Total[b]	100	100

[a]Federal government purchases may be higher than shown since some of the other categories of customers may include contractors for federal agencies.

[b]Figures do not add due to rounding.

Purchases at the Data Center amounted to about $7 million in fiscal year 1983. The prices of Landsat products are designed to recover operating but not building or launching costs. As of August 1983, the prices for photographic images ranged from $26 to $235; the prices for computer-compatible tapes ranged from $650 to $2,800. For the first 9 months of fiscal year 1983, the latest period for which information was available, Landsat operating costs amounted to about $22 million.

Landsat data have a variety of uses, including mapmaking, mineral exploration, crop estimation, and wildlife habitat assessment. More detailed information on the ways federal, private, and foreign entities use Landsat data is provided in the following chapters.

The weather satellites

The U.S. weather satellite systems were first authorized in 1961 when the Congress directed the Department of Commerce to establish a satellite system that would continuously observe and report on worldwide environmental conditions. The government has launched and operated numerous weather satellites in the years since then. At present, the government has four civilian operational weather satellites in orbit--two polar orbiters and two geostationary satellites.

The two polar orbiting satellites circle the earth a total of four times daily to provide global coverage of cloud patterns, surface temperatures, atmospheric humidity, and other environmental data. The two geostationary satellites continually view North and South America and the Atlantic and Pacific Oceans as they orbit the earth above the equator at the same rate the earth turns. The information provided by the geostationary satellites includes cloud motion and wind data, precipitation estimates, and frost data. The satellites are valuable in making daily weather forecasts, in researching the environment, and in detecting and tracking severe storms.

Both groups of satellites use a variety of weather and environmental sensors to obtain the required data. These data are transmitted to two command and data acquisition stations in Wallops Island, Virginia, and Gilmore Creek, Alaska. Because the polar orbiting satellites regularly move beyond transmitting range from these stations, arrangements have been made with the French Government to receive some data at their command and data acquisition station at Lannion, France. These data are then relayed to the United States. In addition to the command and data acquisition stations, there are more than 800 direct readout stations around the world, owned mostly by foreign governments, which receive data at no cost from the polar orbiting or geostationary satellite sensors.

Geostationary satellite images can also be obtained by telephone link. To receive satellite data by this method, a user must acquire appropriate telephone communications and terminal display equipment and pay both an initial connection fee and an annual service fee. The images themselves are provided at no cost.

Historical and analyzed data from both polar orbiting and geostationary satellites are obtained by purchasing the data from NOAA's Satellite Data Services Division or by subscription to NOAA's Weather Facsimile System. This system transmits National Weather Service forecasts and other data via the geostationary satellites.

The capabilities of the polar orbiting and geostationary satellites go beyond sensing weather information from the earth's surface. For example, geostationary satellites carry a data collection system to collect and relay environmental data observed by a variety of remotely located platforms, such as river and tide gauges, buoys, ships, airplanes, and automatic weather stations. The polar orbiting satellites have a similar capability through a French-produced system which not only collects data from moving platforms but also provides information on where the platform was located at the time the data were received by the spacecraft. The newer of the two polar orbiting satellites also has the capability to monitor emergency radio broadcasts from ships or planes through a receiver called Search and Rescue Satellite Aided Tracking.

The federal government is the largest user of weather satellite data. NOAA's National Weather Service, the primary

recipient, uses satellite data to issue warnings about hurricanes, tornadoes, and severe storms; to gather environmental data for daily weather forecasts; and for research. The second largest federal user is the Department of Defense, which uses data from the civil polar orbiters to supplement its own Defense Meteorological Satellite Program. Weather satellite data are also disseminated abroad through a United Nations-sponsored system for the free, international exchange of weather data.

Other users of weather satellite data include state and local governments; university researchers; and private companies and individuals, such as the news media, airlines, and farmers. Chapter 5 of this report provides more detailed information on the users of weather satellite data.

STATUS OF THE ADMINISTRATION'S PROPOSED SALE OF THE SATELLITES

The proposal that Landsat be transferred to the private sector first received presidential endorsement in 1979 during the Carter administration. Following a lengthy review of the nation's space policy, President Carter decided to give NOAA responsibility for operating Landsat and announced the goal of eventually transferring it to the private sector. However, the administration also affirmed its intention to ensure continuity of Landsat data through the 1980's by launching three additional satellites in the Landsat series.

The Reagan administration terminated the government's commitment to ensuring Landsat data continuity through the 1980's because it believed that commercialization can occur more quickly. Instead of launching three more Landsats, the current administration intends to launch only one more. In addition, on July 13, 1981, President Reagan requested the Cabinet Council on Commerce and Trade, chaired by the Secretary of Commerce, to determine the best method of transferring Landsat to the private sector and to assess the advisability of transferring the weather satellites to private ownership. In December 1982 the Council recommended the transfer of Landsat and the weather satellites. President Reagan announced his endorsement of this recommendation on March 8, 1983. In congressional testimony, the Secretary of Commerce said that the administration wants to commercialize Landsat because it believes that the private sector can develop a market for Landsat data better than the government and help the United States retain its international lead in this technology. Commercialization of the weather satellites was proposed to allow a private satellite owner an assured source of revenue while the Landsat market was being developed.

In June 1983, the Secretary of Commerce chartered the Source Evaluation Board on Civil and Remote Sensing to draft a request for proposals (RFP). The Board issued a draft RFP in October 1983 to obtain industry input. The draft RFP would have allowed private firms to bid for one or more of the three systems:

Landsat, the polar orbiting weather satellites, and the geostationary weather satellites. In November 1983, however, the Congress enacted Public Law 98-166, which prohibited the use of funds by the Source Evaluation Board to develop or issue an RFP for the sale or lease of the weather satellites. In response, the Board cancelled plans to issue an RFP for the weather satellites. The final RFP for Landsat was issued on January 3, 1984. Responses to the RFP are due by February 29, 1984.

The objective of the RFP is to establish as quickly as possible a commercial land-observing satellite program which is subject to the least possible government regulation. Offerors are required to submit proposals to build and operate a satellite system to begin operating in 1987, after the last government-built Landsat stops operating. Offerors are also encouraged to buy or lease the government's system for its lifetime. This system includes (1) Landsat 4 and its successor satellite scheduled for launch in March 1984, (2) satellite command, control, and other functions at the Goddard Space Flight Center, (3) ground or other systems for satellite tracking and communications, and (4) data processing and distribution at the Earth Resources Observation Systems Data Center.

According to officials of the Source Evaluation Board, the market for Landsat data is not strong enough to make operation of Landsat profitable at this time. The RFP states that the government is willing to provide financial support, such as loans or loan guarantees, during the early years of private operation and invites offerors to indicate what form of assistance they would prefer, but the government's ultimate objective is to purchase data, over the counter, from a self-sustaining commercial operation. The RFP also indicates that the government is willing to negotiate with a private operator for launch services.

The RFP requires an offeror to specify the type and cost of data and services which it will provide after the transfer. The RFP does not set a limit on the prices that a private operator could charge but does indicate that volume of federal data purchases will depend on data cost. After responses to the RFP have been received and evaluated, the Department of Commerce will select the preferred offeror and propose legislation to the Congress to authorize the commercialization of Landsat. If the legislation is passed, Commerce will contract with the successful offeror for a commercial Landsat system. The Congress can refuse to authorize the commercialization or may pass legislation which requires commercial operations different from those proposed by the selected offeror. Any operating requirement imposed in legislation would control the terms of a contract between Commerce and the commercial operator.

Any legislation authorizing the commercialization of Landsat must balance the financial interests of the private operator against the concerns of Landsat users that unregulated commercial operations will adversely affect their interests. Potential

private operators will in turn consider whether legislatively or administratively established terms and conditions make private Landsat operation economically attractive.

OBJECTIVES, SCOPE, AND METHODOLOGY

As requested by Chairman Brooks and Senators Mathias, Stennis, and Zorinsky, we identified the principal federal, international, and private users of satellite data and their uses of the data and discussed with them which conditions the users believed should be included in the contract transferring the satellites to the private sector. In our discussions with users we used a structured interview approach. Different sets of questions were developed for each of the user groups. Each user within each group was asked the same questions. Their responses have been tabulated in the report. In accordance with the requestors' instructions, we did not obtain agency comments on the report. The audit work on this assignment was done between May and September 1983 and, with the exception of not obtaining agency comments, was performed in accordance with generally accepted government auditing standards.

To obtain information on the federal uses of Landsat and weather satellite data we spoke with officials from 23 agencies. These agencies were in the Departments of Agriculture, the Interior, Commerce, Energy, Labor, Transportation; or were independent agencies like the Environmental Protection Agency, NASA, and the Smithsonian Institution. These users represent most of the federal civilian agencies which made significant use of Landsat and weather satellite data in 1982. See appendix I for a description of how these federal agencies use the satellites.

Information on the international implications of the sale was gathered by interviewing officials from 3 federal agencies, 5 international assistance organizations, and 11 foreign countries. The federal agencies contacted were the Department of State and the major suppliers of satellite data to other countries: the Agency for International Development and the Department of Commerce. Representatives from the World Meteorological Organization and other United Nations' agencies, World Bank, Inter-American Development Bank, and Asian Institute of Technology were interviewed because their organizations have funded projects involving the use of Landsat or weather satellite data. Finally, we visited foreign ministry, space agency, or meteorological officials in Argentina, Barbados, Brazil, France, Germany, India, Italy, Japan, Peru, Thailand, and the United Kingdom. Selection of these countries was made following discussions with officials from the Agency for International Development, NOAA's National Environmental Satellite Data and Information Service, and the National Weather Service. Countries were selected to include representative industrialized and developing countries in various geographical locations that use Landsat and weather satellite data.

We spoke with officials of 28 private and state government organizations selected after discussions with NOAA officials to achieve a representative cross section of nonfederal users.[4] The organizations we contacted are in industries or consumer groups which are among the largest users of satellite data. The users included large and small private weather services, large and small oil exploration service companies, television weather services, data processing companies, a state government, a university, a public utility, and an airline. These groups were selected to include a diversity of satellite data users in a variety of geographical locations. The views on commercialization we obtained were those of organization officials and may not represent formal positions of the organizations themselves. A total of 2,980 nonfederal organizations bought Landsat data from the Earth Resources Observation Systems Data Center in fiscal year 1982. (See ch. 5 for the number of nonfederal users of the various weather satellite data and services.) We also reviewed the Department of Commerce's RFP to determine the extent to which it addressed concerns raised by users about commercialization.

---

[4]Fourteen of the organizations used only Landsat data, 12 used only weather satellite data, and 2 used both.

CHAPTER 2

COMMENTS FROM FEDERAL AGENCY OFFICIALS ON THE COMMERCIALIZATION OF LANDSAT

Most of the federal Landsat users believed that the cost of Landsat data would probably increase under private operation, and almost all believed that increases would cause them to curtail or even stop using Landsat data. Federal users were also concerned that a private operator's efforts to cut costs might result in a reduction in the type and quality of data and services and in remote sensing research and development. The only potential benefit which was mentioned by more than two users was that a private owner would probably improve the marketing of Landsat data. Virtually all of the federal users believed that the sales contract should include terms and conditions that would protect their interests.[1]

The commercialization process has not proceeded far enough to determine how federal costs will be affected or how the character of land remote sensing data may change. However, the RFP for Landsat does address many of the concerns raised by federal users.

BACKGROUND ON FEDERAL USERS OF LANDSAT DATA

Twelve federal civilian departments or independent agencies[2] purchased Landsat data from the Earth Resources Observation Systems Data Center in calendar year 1983:

Department of Agriculture
Department of the Army, Corps of Engineers (Civil Works)
Department of Commerce
Department of Energy
Department of the Interior
Department of Justice
Department of Labor
Department of Transportation
Environmental Protection Agency
National Aeronautics and Space Administration
National Science Foundation
Smithsonian Institution

---

[1]This chapter discusses all federal uses of Landsat except for national security and international assistance. International uses of Landsat are discussed in chapter 3 of this report. National security uses are discussed in our classified report entitled National Security Implications of Commercializing Landsat and Weather Satellites (GAO/C-RCED-84-1, Feb. 1, 1984).

[2]Excluding national security and international assistance agencies.

According to Data Center records these agencies spent about $2.7 million on Landsat products in calendar year 1983 through August 17.[3]

We spoke with program managers from 18 units[4] in seven departments and agencies. These departments and agencies included the largest, regular federal Landsat users. The managers we contacted use Landsat data to support projects which range from estimating worldwide crop production to predicting the course of forest fires. Examples of a few of the uses of Landsat data follow. (See app. I for individual descriptions of the ways federal agencies use Landsat data.)

--The Geological Survey uses Landsat data to assist in activities such as monitoring coastal shoreline changes, assessing the effects of floods and other natural disasters, and producing a national land use/land cover map series.

--The Fish and Wildlife Service uses Landsat data for planning National Wildlife Refuge activities.

--The Foreign Agricultural Service uses Landsat data to help estimate foreign crop production.

--The Bureau of Land Management uses Landsat data to map vast tracts of public lands and for resource inventories.

--The Corps of Engineers uses Landsat data for purposes such as studying the impact different flood levels could have on cities and communities.

---

[3]Data Center records understate federal agency purchases by not including purchases made on the agencies' behalf by contractors.

[4]The Department of Agriculture's Foreign Agricultural Service, Statistical Research Service, Soil Conservation Service, Agricultural Research Service, and Forest Service; the Department of the Army's Corps of Engineers; the Department of the Interior's Geological Survey, Bureau of Land Management, Bureau of Reclamation, Fish and Wildlife Service, National Park Service, Bureau of Indian Affairs, Bureau of Mines, and Office of Surface Mining Reclamation and Enforcement; the Department of Labor's Mine Safety and Health Administration; the Department of Energy; the Environmental Protection Agency; and the National Aeronautics and Space Administration.

38-036 O - 84 - 47

FEDERAL USERS' CONCERNS ABOUT POTENTIAL INCREASES IN THE COST OF LANDSAT DATA

The possibility of increases in the cost of satellite data was the principal concern of most federal users of Landsat data we contacted. Landsat users in 14 of the 18 agencies said that cost increases were likely if the satellite was sold to the private sector. Users believed that a private owner would charge more for Landsat data because the current prices are too low to fully recover costs. NOAA has priced Landsat data to recover operating costs; a commercial operator would charge prices designed to recover the costs of building and launching Landsat as well as operating it. Under federal operation Landsat costs have been high. As of March 31, 1983, the federal government had spent about $477 million to build, launch, and operate Landsat 4; to build a replacement for Landsat 4; and for ground systems.

Users in 16 agencies we contacted believed that an increase in the cost of Landsat data would either prevent them from continuing to buy the data or reduce the amount they could buy. Users in seven agencies said that no satisfactory alternative to Landsat data exists. For example, a Bureau of Land Management official said that Landsat plays a key role in helping the Bureau manage federal lands. According to the official, satellite data is irreplaceable for vast, relatively inaccessible areas such as parts of Alaska.

FEDERAL USERS' CONCERNS ABOUT DATA, SERVICES, AND RESEARCH

Landsat users in 14 of the 18 agencies expressed concern about the type or quality of data and services they would receive from a private owner. These users believed that selling Landsat would result in poorer service, including interruptions or delays in data delivery. Another major concern was that certain types of data used by the agencies might no longer be available. Limited data availability was seen as resulting from the private owner's desire to discontinue unprofitable data types. Seven of the users believed that the products they now buy would be discontinued since they are likely to be low-selling items. In a related issue, users were concerned that a private owner might not continue archiving data for future use since this would probably not be profitable. Some of the users said that archived data was very useful in supporting their agencies' programs.

Officials of seven of the agencies were concerned that the quality of data they received might deteriorate. Users cited inexperience and increased emphasis on operational economies as reasons for possible reductions in data quality.

Seven users believed that research and development would be slowed under private ownership. These users believed that the federal government should continue to perform research and development for Landsat. For example, a Forest Service official said that a private firm might perform some research, but the government would have to do research in areas where commercial profits are unavailable.

TERMS AND CONDITIONS SUGGESTED BY FEDERAL USERS

Officials from 17 of the 18 Landsat-using federal agencies we contacted believed that if Landsat is sold, the federal government should include specific terms and conditions in the sales contract to protect the government's interests. Users from 16 of the 18 agencies supported a provision that would state the type of data that must be collected by the private owner of Landsat. Users from 15 of the agencies believed that standards for data quality should be required in the sales contract. Users in 13 agencies advocated provisions to ensure the timeliness of data delivery, the frequency of data collection, the continuation of research and development, and the establishment of a federal board to oversee the private owner's management of Landsat. All of these provisions were viewed as protecting the agencies' continued access to the type and quality of data needed to support their programs.

RFP TREATMENT OF FEDERAL USER CONCERNS

Full performance characteristics for the commercial Landsat system will not be established until a contract is reached between the government and a private operator. In addition, the costs of Landsat products and the amount of the federal subsidy to the commercial operator will not be known until a contract is signed. However, the RFP does require an offeror to orbit a sensor which provides data equal to or better than the current Landsat operational sensor. In addition, an offeror must describe methods for improving data coverage and timeliness and for ensuring that data quality is not reduced.

The RFP indicates that it is the administration's policy to continue federal research and development. It states that:

> "It is the U.S. Government's strong belief that an aggressive, continuing Federal R & D effort in advanced remote sensing technology is critical to maintaining a U.S. leadership position in civil space technology, as well as to advancing the understanding of changes to global earth processes and their long-term impacts."

In addition, the RFP indicates that the government will continue to archive Landsat data which a commercial operator does not want to inventory.

The RFP also states that the government will have authority to oversee the operations of the commercial land sensing system, including authority to correct deficiencies that might affect operations. According to Source Evaluation Board officials, a federal interagency board will be established to advise the Department of Commerce, which will administer the contract with the commercial operator, on the operator's performance.

CHAPTER 3

INTERNATIONAL IMPLICATIONS OF COMMERCIALIZING LANDSAT

Landsat is used extensively by other countries. These countries are concerned about how commercialization would affect the cost and accessibility of Landsat data. The RFP would permit major changes in the international distribution of Landsat information.

HOW OTHER COUNTRIES OBTAIN LANDSAT DATA

Countries obtain Landsat data in several ways. First, countries purchase data directly from the Department of the Interior's Earth Resources Observation Systems Data Center. According to the Data Center's records, foreign users bought 34 percent of the Landsat tapes and photographic images sold at the center in fiscal year 1983. Receipts from foreign users represented 11 percent of the Center's $7 million sales during the same period.

Second, countries can receive direct Landsat broadcasts. In 1983, foreign countries and the European Space Agency received the data directly from Landsat at 10 ground stations. Ground stations are operated under agreements with the United States, requiring them to pay a $600,000 annual fee and a fee for each Landsat product distributed. These countries also sell the data received by their ground stations to customers in other countries. In 1982, the latest year for which data were available, foreign ground stations received revenues of $2.5 million from distributing about 59,000 Landsat tapes and images.

In addition, foreign countries obtain Landsat data and technical assistance through cooperative activities with federal government agencies. The largest federal user of Landsat data for international projects--the Agency for International Development--budgeted about $500,000 for Landsat data in fiscal year 1983. Other federal agencies that use Landsat to aid in various international efforts include the U.S. Geological Survey, which has sponsored Landsat training courses for the international user community; and the Bureau of Land Management, which has cooperated with other nations on projects involving Landsat data. In addition, the Bureau of Reclamation helped Mexico use Landsat to measure salinity in the Colorado River.

Finally, foreign countries obtain Landsat data through projects funded by international organizations such as the World Bank, the United Nations, and the Inter-American Development Bank.

HOW OTHER COUNTRIES USE LANDSAT

We spoke with government officials responsible for space and remote sensing programs in 10 countries about how Landsat data is used.[1] Nine of these countries operate their own Landsat receiving stations or are members of the European Space Agency, which operates two receiving stations.[2] In addition, we spoke with officials of several international organizations that use Landsat data: the World Bank, the Inter-American Development Bank, the Asian Institute of Technology, and some United Nations' agencies. Generally, these officials told us that:

--Landsat has demonstrated value in a number of areas but is used mostly on a research and development or demonstration basis rather than an operational basis since program managers are still learning how to use it.

--The uses of Landsat data are expected to increase in number and variety as users gain experience and satellite technology advances.

--A commercial market for Landsat data is years away.

--Investments made by developing countries in acquiring the capability to receive and use Landsat data represent significant commitments of their governments' resources.

--Landsat has unique advantages over nonsatellite survey techniques for obtaining broad-scale geographic information.

In the countries we visited, Landsat has been used for a variety of purposes, including mapmaking and inventorying and monitoring natural resources. These Landsat uses are particularly important for the developing countries where less is known about the land and its resources than in the more technically advanced nations. Some examples of Landsat's uses follow:

--Brazilian officials said that Landsat had proven especially valuable for monitoring sugar cane--an important crop used both as food and in manufacturing synthetic fuels. Brazilian space agency officials said that the satellite data were needed because Brazil's large land area made the use of aerial photography for surveying the crop impractical.

---

[1]Argentina, Brazil, the Federal Republic of Germany, France, India, Italy, Japan, Peru, Thailand, and the United Kingdom.

[2]Of the countries we visited, only Peru does not operate a Landsat ground station or is not a member of the European Space Agency.

--Peru has acquired Landsat data from Brazil and the United States to produce its first nationwide topographic map. Peruvian officials said that the nature and location of the nation's natural resources are not fully known because about two-thirds of the nation has never been accurately mapped. The officials said that mapmaking through aerial photography is too expensive and that flying in remote regions of Peru is too dangerous. The officials added that the speed at which Landsat provides information is especially important in a country like Peru, where natural disasters such as earthquakes, landslides, droughts, and floods can rapidly change roads, rivers, and agricultural conditions.

--Thai officials told us that increasing population has caused more and more land to come under cultivation. The impact of this expanded farming was not clear until Landsat images showed deforestation occurring at an alarming rate. Ground surveys and aerial photography had not disclosed the full dimensions of the problem. After seeing the Landsat pictures, the Thai Government strengthened controls on the clearing of forests.

--In India, Landsat's images of shrinking lakes provided graphic evidence of the effects of recent droughts and contributed to government decisions to provide relief to affected areas.

The more industrialized countries use Landsat data for a variety of purposes, including mapping, urban planning, agriculture, and research. For example, the National Remote Sensing Center in Farnborough, England, provides data to governmental entities, commerical organizations, and academic institutions. Governmental entities have accounted for 53 percent of the data sales from this center in recent years.

The European countries we visited believe that while Landsat data are very useful, a commercial market will develop in the next 5 to 15 years only as users gain experience and technology advances.

Foreign officials also told us of some future uses of Landsat:

--Brazil hopes to use Landsat on an operational basis for agricultural crop surveys and improved identification of deforested areas.

--Peru wants to use Landsat for land-use monitoring, monitoring marijuana and coca leaf production, monitoring the effects of floods and droughts, and identifying landslides.

FOREIGN COUNTRIES' CONCERNS ABOUT THE COMMERCIALIZATION OF LANDSAT

Officials of the countries we visited were not opposed to the commercialization of Landsat per se but were concerned about possible changes that private ownership might bring. Specifically, they expressed concern about the potential for

--data sales policies contrary to their economic or national security interests;

--termination of direct satellite transmission to their ground stations or changes in the satellite signal, requiring expensive ground station alterations; and

--increased prices forcing reductions in data purchases.

Data sales policy

The United States has traditionally followed a policy of making Landsat data available to everyone, including the country over which it was sensed, on equal terms. Foreign countries, in turn, are required by their agreements with the United States to distribute data acquired by their Landsat ground stations in the same manner. This data distribution policy has muted criticism by countries about surveillance within their boundaries. Representatives of the developing countries we visited believed that their governments would object if a commercial satellite operator changed this policy. For example, they said that if Landsat data on natural resources in their own countries were available to others but not to themselves, they would be placed at an unfair economic disadvantage. They believed that this type of sales policy might be adopted to increase profits. In addition, they were concerned that as sensors on board the satellites become more sophisticated, the satellites could be used to acquire and distribute military intelligence harmful to their national interests.

Representatives of the Indian Space Research Organization said that one country's use of remotely sensed data from another country raises issues of national sovereignty. They cited a paper prepared for a 1982 United Nations conference on "The Exploration and Peaceful Uses of Outer Space" in which the Indian government said:

> "India has always maintained that surveillance and remote sensing are but two faces of the same coin. . . . This very contentious issue arises out of conflicting national needs and interests which lead to deep mistrust and mutual suspicion of each other's motives among contending nations.

. . . . .

> "Clearly . . . there is a need for timely and unrestricted supply of data from the sensing state to the sensed state. But dissemination of data to third countries should not take place without following accepted and agreed procedures."

Indian officials said that a policy which did not give India equal access to all data acquired on India might lead to complaints by the Indian Government.

In a message delivered to the same United Nations conference, the President of Brazil expressed concern about the possibility that remote sensing could be used against the interests of a sensed country:

> " . . . [remote sensing from space] affects traditional concepts of security, violating the notion of national privacy and . . . marching towards the violation of individual privacy. Remote sensing impinges on the sovereignty of States over their natural resources and it may prejudice the capacity of countries of negotiating the sale of their agricultural products at fair and equitable prices. This is an instrument both valuable and dangerous."

The developed countries have also endorsed open distribution of satellite data. Leaders of several European nations, Japan, and the United States, meeting at Williamsburg, Virginia, in May 1983, approved the following statement of policy:

> "In view of the inherently global benefits of remote sensing, extensive international participation and the strong interest expressed by numerous countries in the United Nations and other international fora, the Summit members recognize the important broader international context within which Summit member remote sensing activities are conducted. In this regard, throughout the above activities, the members of the Economic Summit . . . support the need to assure timely, public nondiscriminatory data dissemination and to seek continued availability of satellite data."

Transmission to foreign ground stations

Officials from several countries were also concerned that a private sector satellite owner would for commercial reasons stop broadcasting to foreign ground stations. Representatives of the developing countries, in particular, believed that their governments had made major investments in equipment, software, and training to receive and use Landsat data and would react negatively to the loss of direct reception. For example, Thai officials reported that about half of the annual budget of their National

Research Council, the principal government agency for sponsoring scientific research, is used for operating a Landsat ground station and processing Landsat data. The officials said that Thailand had recently spent about $10 million constructing the Landsat receiving station and buying equipment, an amount which they consider a major outlay for scientific purposes. Thai officials also said that developing countries would find it very difficult to understand a shutoff of data to their ground stations in view of their significant investments. Thai officials said that Thailand provides a benefit to the entire Southeast Asian region by making data available to other countries at less than its own costs to receive and process them.

The President of Argentina's space agency reiterated to us a position taken by eight Latin American countries represented on the United Nation's Committee on the Peaceful Uses of Outer Space. These countries took the position that nations operating remote sensing satellites should assure countries operating ground stations of continued access to data and assistance in making ground station modifications required by technical changes in the satellites. Representatives of Brazil, one of the countries adopting this position, told us that Brazil had spent about $40 million over 10 years to receive and use Landsat data.

Another concern frequently expressed by foreign officials was that commercial operation of Landsat might result in sharp price increases which would force them to limit their acquisition of data. Foreign government officials generally said that funds for Landsat data were limited, especially since most Landsat uses were in the research and development area. Representatives of several countries said that recent increases in the price of Landsat products had already reduced sales.

In summary, it was clear from our discussions with foreign officials that they regarded Landsat as an important tool for resource management and other purposes and were concerned about disruptions that commercial ownership might bring. Officials in several countries we visited said that the United States had built considerable goodwill abroad and provided effective foreign economic aid by supplying Landsat data worldwide at relatively low prices.

The RFP for Landsat does not address foreign concerns

The RFP does not fully address the concerns raised by foreign Landsat users. The RFP does not require a private operator to continue present relationships with foreign ground stations. Subject to federal government approval, a private operator could terminate agreements with a foreign Landsat ground station operator. In addition, the RFP does not require the private operator to retain the current U.S. policy of equal data distribution. The private operator could sell data on a country's resources to outsiders for their exclusive use. The RFP does not indicate the

criteria the government would apply to requests by a private operator to terminate transmission of data to foreign ground stations or revise the U.S. government's traditional policy of equal data distribution. The private satellite operator could set prices for foreign customers at its discretion.

MATTERS FOR CONSIDERATION BY THE CONGRESS

International reaction to a commercial Landsat system which quickly stopped broadcasting directly to foreign ground stations and denied a country information developed from remote sensing over its national territory is likely to be negative. In deciding on legislation to authorize the transfer of Landsat to the private sector, the Congress should consider whether a private Landsat operator should be required to

--continue present arrangements for broadcasting data to foreign ground stations under terms and time frames specified by the Congress and

--continue the traditional U.S. government policy of providing a sensed country equal access to data obtained on its own territories and activities.

CHAPTER 4

COMMENTS FROM NONFEDERAL USERS OF LANDSAT

Thirteen of the 16 nonfederal users of Landsat data we contacted were opposed to commercializing the current Landsat system at the present time.[1] Most of these believed that further market and technological developments are necessary to make the system commercially viable. Most users believed that a single company would not have the resources necessary to operate the current Landsat system. The majority of the users were concerned that a private company's inability to meet expenses would negatively affect data prices, continuity and availability of data, and investment in research and development. Six users--including those in the value-added service business[2]--were also concerned about the private owner having a monopoly of satellite-sensed land data.

Four of the 16 Landsat users cited potential benefits from commercialization, such as improvements in quality and marketing of data and services. Users also made suggestions for terms and conditions the government should include if commercialization takes place.

BACKGROUND ON NONFEDERAL USERS OF LANDSAT DATA

Nonfederal users purchase Landsat images and computer-compatible tapes from the Earth Resources Observation Systems Data Center in Sioux Falls, South Dakota. However, some of the users acquire additional data directly from foreign ground stations and through trades with other users. The following table shows the number of nonfederal U.S. customers by group at the Data Center in calendar year 1982 (the latest year for which information was available).

---

[1]See chapter 1 for details on the nonfederal users we interviewed. Also, the views we obtained on commercialization were those of organization officials and may not represent formal positions of the organizations themselves.

[2]A value-added service is any service that is added to the raw data after the data are processed and formatted by the government for public dissemination. Such services would include making those products more useful to end users by enhancing, analyzing, and interpreting the standard satellite film or computer tape products.

Nonfederal Users of Data Center FY 1982

Nonfederal users	Number
Colleges/universities[a]	323
State and local governments[b]	73
Industry	1,041
Other or unclassified	1,543
Total	2,980

[a]Since the University of Alaska acts as a distribution center for other academic institutions, the actual number of college or university users may be higher.

[b]Includes an unknown number of foreign embassy purchasers.

The following table shows the number and dollar amounts of image and digital items sold to nonfederal U.S. users by the Data Center in fiscal years 1981 to 1983.

Summary of Landsat
Data Sales to Nonfederal U.S. Users FY 1981-83

	Image items		Digital items		
FY	No.	Dollar amount	No.	Dollar amount	Total dollar amount
1981	51,511	$758,617	2,176	$439,972	$1,198,589
1982	39,109	777,914	2,487	612,580	1,390,494
1983	9,269	471,543	585	329,660	983,685[a]

[a]Includes thematic mapper and other new products, totaling $182,482, which are not included as multispectral scanner image or ditigal items.

Landsat data are used in a variety of ways in the nonfederal sector. For example:

--Energy exploration companies use Landsat data to develop reconnaissance maps which are used in oil, gas, and mineral exploration operations.

--Value-added service companies use the data to provide various products and services, e.g., geological and

engineering studies, resource maps, and complete computer systems for processing and displaying Landsat data.

--State governments use Landsat data for mapping and surveying agricultural lands, marine environments, and other natural resources.

--Universities use satellite data to aid in solving engineering, geological, agricultural, and natural resource problems and as a teaching aid.

NONFEDERAL USERS' CONCERNS ABOUT COMMERCIALIZATION OF LANDSAT

Most users opposed the immediate commercialization of the current Landsat system. Eleven users believed that a private company would not have the resources to make the current system commercially viable and would raise Landsat data prices significantly to defray the system's high operational costs. Thirteen were also concerned that a private company's attempt to cut its operational costs would adversely affect availability or continuity of data and investment in Landsat research and development. Twelve of the 16 users believed that since a private company would not invest in the costly, high-risk research and development necessary to advance the system's technology, commercialization would jeopardize potential future Landsat applications and the U.S. position as world leader in land remote sensing. Half of the users said that the system was not now commercially viable and that attempting to commercialize it would retard its development.

Six users--including value-added service businesses--were concerned that a monopoly would be created if a single company owned and operated the system. These users and six others were concerned that a private operator could exercise its proprietary control of the Landsat system to discriminate in its distribution of the data and charge unreasonable prices. This control could jeopardize the existence of companies in the value-added industry, most of which are small businesses.

The table on page 24 summarizes the nonfederal users' opinions and concerns.

Potential benefits cited by nonfederal Landsat users

The majority of the users could not see any benefit to selling Landsat. However, four users believed that transferring the system to the private sector could result in a savings to the government. Four users also believed that a private company would improve on the quality and timeliness of service of the Earth Resources Observation Systems Data Center.

Summary of Nonfederal Landsat Users' Opinions and Concerns Regarding Commercialization

User's organization[a]	Opinion on immediate commercialization of the entire Landsat system	Would commercializating Landsat create problems in the following areas?			
		Monopoly	Discriminatory/ unreasonable pricing	Continuity and quality of data or service	Decrease in research and development
American Soc. of Photogrammetry	Opposed	No	Yes	Yes	Yes
Arco Oil & Gas Co.	Opposed	Yes	Yes	No	Yes
Amoco Production Co.					
Bechtold Satellite Technology Corp.	Opposed	Yes	Yes	Yes	No
Cartwright Aerial Surveys	Not opposed	No	Yes	Yes	Yes
Earth Resources Data Analysis Systems	Not opposed	Yes	Yes	Yes	No
Earth Satellite Corp.	Opposed[b]	Yes	Yes	No	Yes
An exploration geologist	Opposed	No	No	Yes	Yes
The GEOSAT Comm., Inc.	Opposed	No	No	Yes	Yes
Metrics, Inc.	Not Opposed	No	No	No	No
Mobil Research & Development Corp.	Opposed	No	Yes	Yes	Yes
Pecten International Co.	Opposed	No	Yes	Yes	No
State of Florida Department of Transportation, Topographic Bureau	Opposed	Yes	Yes	Yes	Yes
Sun Exploration & Production Co.	Opposed	No	Yes	Yes	Yes
Terra-Mar	Opposed	No	No	Yes	Yes
University of Florida	Opposed	No	Yes	Yes	Yes

[a]The views expressed were those of organization officials and may not represent formal positions of the organizations themselves.

[b]Opposed if Landsat operator could enter the valued added business, which the RFP permits.

NONFEDERAL USERS' SUGGESTIONS FOR COMMERCIALIZATION TERMS AND CONDITIONS

Ten users recommended that the government ensure the continuity of long-term, high-risk land remote sensing research and development. The users believed that strong government support is necessary to stimulate development of new technology in the field. A few users expressed concern that if the United States did not maintain a viable system, foreign satellite owners might control the land remote sensing market.

Eight users also recommended that controls be established --e.g., price regulations and performance standards for quality of data and service--if a single company owns and operates Landsat.

Seven users recommended that the commercialization of the Landsat system should be a staged process commencing with the ground segment. For example, some suggested that the data distribution functions carried out by the Earth Resources Observation Systems Data Center might be turned over to the private sector first. They believed that if the government continues operating Landsat's space segment and performing high-risk research and development, the private sector could develop (1) a viable market for Landsat products and (2) "next generation" computers to keep in step with sensor technology. The users believed that during the transition period the value-added industry would play an important role in marketing Landsat products. One user also believed that as Landsat technology advances, a range of industries would develop to provide launch, reception, and dissemination services aimed at meeting the needs of the market.

How the RFP addresses nonfederal users' concerns

The RFP addresses some of the concerns raised by nonfederal domestic users of Landsat. As discussed in chapter 2, the RFP indicates that the government will continue to perform research and development on remote sensing from space. In addition, the RFP requires a minimum technical capability for a commercial Landsat operation and requires the private operator to describe the performance features of its system. However, the RFP does not permit a phased approach to the commercialization of Landsat, and it permits the private operator to enter the value-added business.

MATTERS FOR CONSIDERATION BY THE CONGRESS

Fundamental purposes of the RFP are to rapidly divest the government of its land remote sensing operations and to encourage the commercial development of land remote sensing with minimum government supervision. Therefore, the RFP calls for the immediate takeover of the entire Landsat system, satellite and ground operations included, and does not establish special safeguards for the protection of value-added businesses. Therefore, in

considering legislation to commercialize Landsat, the Congress should consider two questions:

--Should a phased approach to the private operation of Landsat, beginning with the data distribution functions currently carried on by NOAA, be an option to controlling the whole system?

--Should protection be provided to firms in the value-added business to enable them to compete with a private Landsat operator? For example, legislation might require the Landsat operator to make data available to all value-added firms on the same terms and as soon as the data are ready for analysis by the operator itself.

38-036 O - 84 - 48

CHAPTER 5

DOMESTIC AND FOREIGN USERS' CONCERNS ABOUT COMMERCIALIZATION OF THE WEATHER SATELLITES

Foreign governments, federal agencies, and other U.S. organizations use weather satellite data chiefly for monitoring and forecasting weather, particularly severe and potentially dangerous weather. The data are also used to route ships and airplanes, make agricultural projections, and for research. Most foreign nations participate in the United Nations' World Meteorological Organization, which arranges for the free international exchange of weather information, including satellite data. The United States, as well as foreign nations, benefits from this exchange.

Although Public Law 98-166 prohibited the commercialization of the weather satellites, we are reporting the information we collected on these satellites at the request of Members of Congress who asked for this review.

FEDERAL USERS OF WEATHER SATELLITE DATA

All of the federal users of weather satellites we contacted were concerned about the impact of commercialization on the price of weather satellite data. Most were also concerned about service. The draft RFP issued in October 1983 recognized several of these concerns. However, the transfer process did not proceed far enough to determine the impact of commercialization on prices or whether commercialization agreements would have ensured contractor performance satisfactory to all federal users. To obtain the views of federal users of weather satellites, we spoke with officials from seven agencies: the Bureau of Land Management, Bureau of Reclamation, Coast Guard, Federal Aviation Administration, National Weather Service, Environmental Research Laboratories in NOAA, and the Smithsonian Institution. (See app. I for individual descriptions of the ways federal agencies use weather satellite data.)

Background on federal users of weather satellite data

Federal agencies obtain imagery, measurements of the environment, and other data from the weather satellites. The following table shows various ways federal users[1] obtained satellite data in fiscal year 1983.

---

[1]Excludes national security agencies.

Federal department	Direct broadcast[a] receiving stations	Telephone transmission subscribers	Data collection systems platforms		Archived data[b] product deliveries
			G[c]	P[d]	
Agriculture			199		770
Commerce	17	56	436	96	14,077
Interior			1,443		47
Transportation	4	25		10	159
NASA	5	6			9,820
Other	1	4	85	17	8
Total	27	91	2,163	123	24,881

[a]Direct, real-time satellite transmissions of images, environmental data, and search and rescue distress signals and delayed transmissions of processed data.

[b]Includes pictures, tapes, and other products, such as charts.

[c]Geostationary satellites.

[d]Polar orbiting satellites. Figures show number of platform years. For example, two buoys used for 6 months each equal 1 platform year.

Federal users pay NOAA only for archived data[2] and pay a French firm for use of the data collection system on board the polar orbiting weather satellites. However, each agency buys its own equipment to receive and use the satellite data and data collection platforms, such as buoys and other remote sensors.

The federal agencies we contacted use the satellite data in various activities. The largest user of weather satellite data, NOAA's National Weather Service, uses the data to provide weather forecasts to the general public and to issue warnings against such destructive natural events as hurricanes, tornadoes, and floods. Other federal applications include protecting life and property through forecasting hazardous weather for pilots, monitoring icebergs, and locating aviation or boating accident victims; managing public resources under jurisdiction of the federal government, such as fire protection activities on lands managed by the Bureau of Land Management; monitoring the condition of the environment, such as detecting solar disturbances by the NOAA Space Environment Services Center and collecting weather information from remote locations; and advancing scientific knowledge about the atmosphere, oceans, and lands, such as the Smithsonian Institution's monitoring of volcanic eruptions.

[2]A small connection and yearly maintenance fee is also collected for a hookup allowing a user to receive telephone line transmission of geostationary satellite data. The data are free.

Concerns of federal users

All of the federal users of weather satellites we contacted had some reservations about the possible consequences of selling the satellites to the private sector. In general, the concerns focused on (1) increased costs of satellite data and (2) decreased data and services under private ownership. All federal users expected costs for satellite data to increase and expected problems with the data and services provided by a private owner. Officials in six of the seven agencies we contacted also believed satellite research and development might suffer.

Federal officials mentioned several reasons for these concerns about commercialization. Four federal users attributed possible cost increases and changes to or discontinuation of data or services (types of data collected, data archives, and methods for providing data) to the need for a private owner to make a profit. Three believed the administrative process of buying satellite data from a private firm would be more costly. Two also believed that additional costs for data processing equipment and software would result from changes to the format of the data provided to federal agencies. Five users expected poorer service (timeliness and data quality problems), particularly during a transition period, because a private firm would be less responsive to the needs of federal agencies and not have the technical skills and expertise or working relationships with federal agencies.

Federal officials in all of the seven federal agencies we contacted believed that specific terms and conditions were needed on the quality and timeliness of data delivered to federal users. They explained that such terms and conditions were needed to prevent deterioration of quality and timeliness or provide incentives for high quality services. Officials of the National Weather Service responsible for issuing forecasts of hurricanes and severe storms were especially concerned that the sale of the weather satellites be made on terms which assured their continued access to timely, useful data.

Federal officials in four agencies believed that advances in weather satellite technology might be slowed because of private ownership. Weather Service officials, for example, believed that a private operator would not be as familiar with National Weather Service needs as a government operator.

RFP treatment of
federal users' concerns

The RFP proposed by the Department of Commerce addressed many of the concerns expressed by federal users of weather satellites. The RFP required the private operator to provide present services such as direct broadcasting, data collection services, and relaying search and rescue distress signals. The government was to receive all satellite data from the private operator. Federal agencies would have continued to receive, free of charge, the

services they now receive from the National Weather Service. The RFP specified what items were to be delivered, in what manner, and at what times.

The government was to continue present services such as the telephone line transmission of geostationary satellite data, archives, and free international exchange of satellite data. Federal research and development programs were to continue, and test flights of new sensors and equipment on operational satellites were anticipated. For example, the search and rescue equipment on the most recent polar weather satellite is part of an international cooperative research and development program. The government wanted similar arrangements for flights aboard commercial satellites.

One concern of federal users of weather satellites was not satisfied by the RFP. Some cost increases for data and services would have been likely because the data collection systems were to be fully commercialized services. Currently, users of the polar orbiters' data collection system service pay a French firm for processing data. NOAA processes and provides the data from the geostationary satellites' data collection system free of charge. Under commercialization, federal users would have been expected to pay for such services.

FOREIGN USERS OF WEATHER SATELLITE DATA

How other countries receive U.S. weather satellite data

U.S. weather satellite data is shared with other countries in several ways: through a United Nation's exchange system, via direct satellite transmissions of sensor readings and other information, and by relaying transmissions of data collection platforms located in oceans and rivers. The most extensive method of satellite data distribution involves the United Nations' World Meteorological Organization. Most nations participate in the Organization's Global Telecommunications System, a communications system for sharing weather information worldwide in a program called the World Weather Watch. The United States and other nations that operate weather satellites include satellite data in the system. U.S. weather satellite data are also transmitted directly to ground stations in other nations. As of February 1983, NOAA reported that 120 nations owned more than 800 ground stations for the direct reception of U.S. weather satellite data. Foreign countries also use the satellites' data collection systems.

How other countries use U.S. weather satellite data

The U.S. weather satellites are important to other countries for predicting severe weather, for improving the accuracy of longer term weather forecasting, and for supplying weather

information for areas not covered by more traditional data sources. One of the most critical uses of the weather satellites is in the Caribbean where a geostationary satellite provides information for predicting and tracking life-threatening hurricanes. The Director of the Barbados weather service said that without direct readout from the satellite he could not provide adequate hurricane warnings. The Director pointed out that time for preparation before a hurricane is critical for saving lives and property. He also said that hurricane warnings have more credibility with the general population when satellite imagery can be viewed on television.

Satellite data are also important for more general weather forecasting. The Director of the weather service in Barbados said that the polar orbiting satellite is essential for weather forecasts in the Caribbean. In general, the greater the number of reporting points for temperature, wind speed, and other environmental phenomena, the more accurate a weather forecast will be. In recent years, there have been too few ships in the Atlantic, east of the Caribbean, acting as reporting points, so that Barbados and other Caribbean nations depend on the satellite data. According to the Director of the weather service in Brazil, the satellites are crucial in the Southern Hemisphere to track fronts and for the quantitative evaluation of fronts. Weather officials in Japan and Thailand told us that the U.S. weather satellites made important contributions to longer term forecasts and to monitoring ocean areas.

The satellites serve several other useful purposes, such as providing hydrographic data, contributing data to international weather research projects, aiding international search and rescue missions, and conducting crop inventories. For example:

--Brazilian weather officials said that without the transmission via the geostationary weather satellites of information from data collection platforms on the rivers, it would be difficult to learn about flooding and droughts in remote regions of the country.

--The World Meteorological Organization operates research programs to promote better understanding of the environment. The U.S. weather satellites provided data for the First Global Atmospheric Research Program of 1979, a coordinated effort of several World Meteorological Organization members to solve some of the major questions about the atmosphere for long-term weather prediction.

--The latest U.S. polar orbiting satellite, launched in March 1983, has the capability to locate emergency broadcasts of aircraft and oceangoing vessels in trouble. An example of the international cooperation involved in satellite search and rescue efforts occurred in 1982 when a Soviet weather satellite picked up the emergency transmitter signal of a downed aircraft in

Canada. The Soviets relayed the location of the aircraft via the U.S. Coast Guard.

--The United Nations' Food and Agriculture Organization uses the U.S. polar orbiter satellites for broad-scale views of natural resources in short time periods. The Organization's Remote Sensing Center provides technical assistance and training for many nations using these data.

--The Agency for International Development uses the weather satellites for a disaster early warning system which indicates possible food shortages triggered by climatic changes. This enhanced capacity to identify and evaluate disaster conditions provides greater lead time for planning food assistance strategies. The early warning information can be provided 30 to 60 days prior to the harvest of grain crops or 3 to 6 months prior to an actual food shortage. According to Agency for International Development officials, the better prepared a country is for disaster, the less probability there is of death, suffering, and property damage.

The United States benefits from the international sharing of weather information

Weather data have been shared freely among nations for more than a century. Besides ground and upper air observations obtained through the World Meteorological Organization system, the United States can receive direct readouts from other nations' weather satellites. Western Europe, Japan, and India have geostationary satellites and the Soviet Union has a polar orbiting satellite. The United States can obtain data directly from each of them. The European, Japanese, and United States satellites share a common Weather Facsimile transmission frequency allowing for the sharing of weather data.

Foreign nations have also contributed sensors and technical support for U.S. polar orbiting satellites. The United Kingdom provides the stratospheric sounding unit, a temperature-reading device on board the polar orbiters, at no cost to the United States. France and Canada jointly provide the search and rescue instrument. France provides the data collection system on board the polar orbiting satellites at no cost to the United States. The French space agency also acts as a backup to NASA after the launch of a polar orbiter. The French agency has the capability to receive soundings and take command of the satellite.

The United States benefits from free international exchange of weather data by getting

--worldwide information needed for more accurate longer range predictions of U.S. weather,

--overseas weather information to support its worldwide commercial and defense interests, and

--data it could otherwise acquire only by spending additional funds for observations in foreign areas and by receiving observations that might be impossible to make without foreign cooperation.

Concerns of foreign users

The administration's March 1983 decision to proceed with the commercialization of the weather satellites caused various countries to express concern about its possible consequences. In addition, representatives of the foreign weather services we met with had concerns. The concerns centered mainly around (1) charges for satellite data to the World Meteorological Organization, (2) the termination of free transmission of compatible data to foreign ground stations, and (3) disruptions in international cooperation.

The United Kingdom's Department of Industry prepared a position paper on the proposed commercialization, urging continued international cooperation and free data exchange. The United Kingdom paper stated that:

"The UK considers that any scheme for commercialization of the provision of meteorological satellites in the USA should take account of existing and potential international agreements to provide instruments as contributions towards the US polar-orbiting satellite system. There are doubts regarding the feasibility of such agreements under the new system. These uncertainties are already causing difficulties and delays in securing financial authority for UK participation in the proposed Advanced Microwave Sounding Unit."

. . . . .

"The UK strongly recommends that any internal rearrangements within the USA should safeguard the existing principle that no charge be made for meteorological observations provided to other national meteorological services. This should extend to data directly broadcast by meteorological satellites and the derived data (e.g. temperatures, winds) exchanged through normal meteorological telecommunications channels. No contrary decision should be made without a full examination of the likely consequences of charges being made for all meteorological observations on a world-wide basis."

The Canadian Government prepared a paper indicating concern about the sale as follows:

> "Canada's data collection activity, especially in the north, at least equates with the U.S. contribution of satellite acquired data. Thus, on a bilateral basis, both countries make essential contributions to weather prediction in North America. It is our hope that the free exchange of weather information will continue between Canada and the USA, and on a global basis."

In June 1983, the World Meteorological Organization held its quadrennial conference in Geneva. The Organization reaffirmed the principle that "data and products available within the World Weather Watch system should be exchanged freely and without charges between members. . . ." Another principle stated that "meteorological satellites, both polar orbiting and geostationary, in their observation, data collection and dissemination roles, are of fundamental importance for the operation of the WWW [World Weather Watch]."

The RFP would have continued international arrangements for use of the weather satellites

The cancelled RFP for the weather satellites addressed most foreign concerns about the weather satellites. The RFP would have required that the U.S. government review and approve or disapprove decisions of the private operator on matters and issues involving foreign policy and international obligations and that:

--The private operator must continue the functions of the foreign sensors provided by France, Canada, and the United Kingdom, or replace those instruments.

--The private operator provide the same volume and quality of data to the World Meteorological Organization network via NOAA as is currently provided.

--The private operator continue the current volume and quality of weather satellite data to foreign ground stations via direct readout.

--The U.S. government continue to archive the data.

Despite these RFP provisions, representatives of weather services in Argentina, Barbados, and Brazil told us that commercialization reduced the prospects for continued, long-term, free exchange of weather information and made international cooperation more difficult. These officials said that continued free access to data in the future would be less certain with the

commercial operation of the satellites. They said they preferred continued operation by a government agency.

NONFEDERAL USERS OF WEATHER SATELLITE DATA

Ten of the 14 nonfederal weather satellite users we contacted were opposed to commercialization of these satellites at this time.[3] Even those nonfederal users that were not opposed to commercialization had several concerns which they believed should be addressed by the government before transferring the systems to the private sector. Nearly all of the users, whether or not they opposed commercialization, were concerned about the danger of a private owner having a monopoly on the supply of weather satellite data with a resulting negative impact on prices, service, and research. Some users indicated that commercialization, with proper government regulation, could benefit both public and private users.

Background on nonfederal users of weather satellite data

Nonfederal users obtain weather satellite data from either the geostationary or polar orbiting satellites. Users obtain real-time data from the satellites if they have their own receiving stations, referred to as direct readout stations. Users obtain near real-time geostationary satellite data via telephone line. Archived data are obtained from NOAA's Satellite Data Services Division or by subscription to NOAA's Weather Facsimile system. Nonfederal entities also use the weather satellites' data collection systems. The following table shows the number of nonfederal users of the various forms of weather satellite data.

---

[3]The views we obtained on commercialization were those of organization officials and may not represent formal positions of the organizations themselves.

Nonfederal Users of Weather Satellite Data

	Number of nonfederal users
Direct readout stations	208 (as of Jan. 1, 1983)
Subscribers to geostationary satellite telephone line transmission[a]	73 (as of Jan. 17, 1983)
Archived data buyers	724 (from Oct. 1, 1982, to Aug. 19, 1983)
Weather facsimile subscribers	69 (as of May 31, 1983)
Data collection system subscribers	311 (as of Aug. 1, 1983)

[a]These are primary subscribers; an unknown number of other users receive a secondary transmission of data from the primary subscribers.

Nonfederal users pay the government only for the ability to receive telephone line transmissions of geostationary satellite data and archived data. To obtain the geostationary satellite data, a user pays an initial fee of $1,000 and a yearly service fee of $100. For archived data, user fees, which run up to $175 for an image and $154 for a computer tape, depending on the product purchased. The following table shows the numbers and dollar amounts of archived computer tapes and photographic products sold by NOAA to nonfederal U.S. users in fiscal years 1981 through August 19, 1983.

Summary of NOAA's Archived Weather Satellite Data Sales FY 1981-83

	Photographic products		Computer tapes		
FY	No.	Dollar amount	No.	Dollar amount	Total dollar amount
1981	13,125	$71,524	671	$49,649	$121,173
1982	10,389	109,253	467	61,432	170,685
1983 (to Aug. 19)	7,974	93,678	475	64,656	158,334

Weather satellite data are used in the nonfederal sector in a wide variety of ways by a wide variety of users. For example:

--State and local governments use satellite data to issue storm and freeze warnings to their residents to protect lives, homes, farms, and businesses.

--Television and radio stations use satellite data in preparing weather forecasts which are broadcast to the public.

--Private companies use weather satellite data for numerous purposes, such as to route airplanes and transoceanic ships, plan construction of offshore oil exploration projects, develop agricultural crop production estimates, plan agricultural irrigation and pesticide spraying activities, and predict demand for natural gas and electrical power.

--Colleges and universities use satellite data in performing basic and applied research for agriculture, water management, data processing, and other projects.

--Private individuals use satellite data (via their own receiving stations) to obtain up-to-the-minute weather information for personal use.

Concerns of nonfederal users

As the table on page 38 shows, all 14 nonfederal users we spoke with expressed some concern about the proposed commercialization of the weather satellite systems. Nearly all users were concerned that commercialization might create a monopoly for the single, private owner of the entire satellite system. Users were concerned that the private owner would not only have complete control of the "raw" satellite data but, if unchecked, would eventually have a monopoly over the value-added service market.

Many of the users' other concerns--unreasonable and discriminatory data prices, discriminatory data access, and decreases in quality of data and service--were directly related to the potential for monopoly. These users said that the creation of a monopoly with power to set discriminatory or unreasonable prices and discriminatory sale policies violated the principles of free enterprise and open competition. They also explained that decreases in quality of data and service could have disastrous effects; for example, if satellite data are disrupted or of such poor quality that a freeze in a citrus region or a hurricane off the coast is not accurately forecast, lives and millions of dollars in property could be lost. Four users expressed further concern that if a monopoly existed, the government and taxpayers would incur costs to regulate and audit the private owner in addition to the costs the government would have to pay to receive the data.

Four of the 14 users we contacted said that government regulation could control the problem that a monopoly on satellite data could cause. They believed that, even if it had a monopoly, the private owner would charge reasonable prices and provide acceptable service because to do otherwise would severely limit sales

Summary of Nonfederal Weather Satellite Users' Opinions and Concerns Regarding Commercialization

User's organization[a]	Opinion regarding commercialization	Would commercializing weather satellites create problems in the following areas? Monopoly	Discriminatory unreasonable pricing	Discriminatory access to data	Continuity/ quality of data or service	Additional cost to government/ taxpayers	Decrease in research and development
Earth Satellite Corp.	Not opposed	Yes	Yes	Yes	No	No	Yes
Eastern Airlines	Opposed	Yes	Yes	Yes	Yes	[illegible]	Yes
Environmental Satellite Data, Inc.	Opposed	Yes	Yes	Yes	Yes	No	Yes
Florida Weather Service, Inc.	Opposed	Yes	Yes	Yes	Yes	Yes	Yes

[a]The views expressed were those of organization officials and may not represent formal positions of the organizations themselves.

and profits. One user believed that a private owner could not adequately serve all end users throughout the nation and, therefore, would not monopolize the value-added industry.

Examples of other areas of concern follow:

--Ten users expressed concern that under private ownership, weather satellite research and development would suffer. They believed that a private owner would not have the resources or incentives to undertake the expensive, high-risk research and development necessary for continued technological advances in satellite sensing and data processing. One user questioned whether the federal government would or should continue to do expensive research and development only to have the results turned over to a single, private company.

--Twelve users believed that weather information (including satellite data) is a public good and that providing this information should therefore be a governmental function. They also told us they were satisfied with the data and service provided by the government; they viewed commercialization as resulting in few benefits and many potential problems to the government and users.

--Twelve users also were concerned that the public investtment in the satellites would not be recovered in a sale and that commercialization would increase government costs. Taxpayers, they told us, have spent millions of dollars to develop the satellite systems to their present status. These users believed that commercialization would undoubtedly lead to taxpayers paying, directly or indirectly, for the data. They believed that having taxpayers pay a private company's profit margin for data coming from the taxpayers' own investment would not be fair.

Potential benefits cited by nonfederal weather satellite users

Six of the nonfederal users we contacted said that private ownership of the weather satellites might provide some benefits because a private owner's profit motive would result in lower costs and better service to customers. According to these users, a private owner would be better able to

--quickly respond to the individual needs of users,

--quickly implement advances in satellite and data processing technology,

--efficiently and effectively operate the satellite systems,

--improve the marketing of data products, and

--save the government and taxpayers money in the long run.

One user believed that commercialization would be a first step toward streamlining and reducing the National Weather Service's operations. This user believed that the private sector is better able to provide localized weather information and services to the public and, furthermore, that forecasters currently employed by the National Weather Service would be better utilized if they were employed by private companies providing such local weather services.

Nonfederal users' suggestions for commercialization terms and conditions

The table on page 41 summarizes the nonfederal users' suggestions for terms and conditions the government should have required if commercialization of the weather satellites had occurred. Most users indicated that these suggested terms and conditions should have been clearly defined and explained in the government's request for proposals for the weather satellite systems.

Summary of Nonfederal Users' Suggestions for Terms and Conditions for Commercialization of Weather Satellites

Nonfederal user's organization[a]	Ensure nondiscriminatory/ reasonable prices	Ensure equal access to data	Establish performance standards[b]	Prohibit owner from value-added industry	Regulate similar to public utility
Earth Satellite Corp.	Yes	Yes	Yes	Yes	No
Eastern Airlines	Yes	Yes	Yes	No	Yes
Environmental Satellite Data, Inc.	Yes	Yes	Yes	Yes	No
Global Weather Dynamics, Inc.	Yes	Yes	No	Yes	Yes
Gordon Barnes Weather Sevice	Yes	Yes	Yes	No	Yes
Gulf Coast Weather Service and WTVT Weather Service	Yes	Yes	Yes	No	Yes
Harris Corp.	Yes	Yes	Yes	Yes	No
Nowcasting, Inc.	Yes	Yes	Yes	Yes	Yes
Oceanroutes, Inc.	Yes	Yes	Yes	Yes	No
Pacific Gas and Elec. Co.	Yes	Yes	Yes	No	Yes
Robert Ryan, Meteorologist	Yes	Yes	Yes	No	Yes
University of Florida	Yes	Yes	Yes	No	No

[a]Two users did not express any views on sales terms because they said that they were opposed to commercialization on any terms. Also, the views expressed were those of organization officials and may not represent formal positions of the organizations themselves.

[b]This column includes performance standards for continuity and quality of data and service, fulfillment of international agreements, fulfillment of federal agencies' and national security requirements, and research and development requirements.

As the table shows, nearly all nonfederal users who offered suggestions told us that the government should

--ensure nondiscriminatory and reasonable data prices for all users,

--ensure equal access to data by all users, and

--establish performance standards which the private owner must meet.

Six users believed that the private owner should be prohibited from performing value-added services. They explained that a private owner with complete control of the data could destroy all competitors in the value-added industry. On the other hand, some of the users said that barring the owner from the value-added industry would lead to many potential private owners not bidding for the weather satellite systems. Seven users told us that the satellite owner should be regulated by the government in the same manner as public utilities.

How the RFP addressed nonfederal users concerns

The cancelled weather satellite RFP addressed most of the concerns raised by nonfederal domestic users of weather satellites. The RFP stated that the private operator was to provide all satellite data to the U.S. government, which would have continued to process and distribute that data and its products to government agencies and private sector organizations. The RFP indicated that the government would have continued current services to the private sector, such as telephone line transmission of geostationary satellite data and archiving data, and required the private operator to continue direct broadcasting of sensor data and weather facsimile information to privately owned receiving stations. A private owner would have been expected to meet the quality standards already in use for current weather satellite systems. The government would have continued to do research and development on weather satellite technology.

On the other hand, the private operator would have been permitted to enter the value-added business for weather data and charge a fee for the use of the weather satellites' data collection systems. The communications channels on these systems are rapidly becoming fully subscribed. Present users of these systems might have faced price increases under commercial operation.

APPENDIX I

HOW FEDERAL AGENCIES USE LANDSAT AND THE WEATHER SATELLITES

DEPARTMENT OF AGRICULTURE

Foreign Agricultural Service

The Foreign Agricultural Service monitors and forecasts crop production on a global basis and disseminates the information to the general public. The crop forecasts are based on a variety of information, such as U.S. embassy reports, press reports, foreign government publications, trade and weather reports, and land and weather satellite data. The Service's primary means of estimating foreign crop production is through onsite inspections by U.S. embassy personnel. Satellite data are used as a supplement to refine the estimates and make them more reliable. In certain countries, however, satellite data are the primary source of information because the travel of U.S. embassy personnel is restricted or the area of coverage is too large to use embassy personnel. For instance, the Soviet Union restricts onsite inspections; China and Brazil have extensive crop areas.

Service crop production analysts told us that Landsat is a useful tool for estimating crop production because it provides a relatively high-resolution image of crops. The weather satellites are also useful to the Service because they provide continuous time comparisons of the same area. Service officials told us that Landsat is not expected to replace ground observation as the primary information-gathering tool in the foreseeable future because the science of interpreting Landsat images is not precise. Vegetation is shown on images as "red," and the intensity of the color indicates the potential yield of the vegetation. Uncertainty exits, however, in estimating the yield based on the color intensity. Officials said that the Foreign Agricultural Service does not plan to increase its use of satellite data.

Statistical Reporting Service

The Statistical Reporting Service is responsible for preparing domestic agricultural statistics, including estimates of domestic crop production. The Service, like the Foreign Agricultural Service, uses onsite farm inspections as its primary tool for estimating crop production. Over the years, the Service has conducted or participated in a number of studies to assess the usefulness of Landsat. Generally, the studies' results have shown that Landsat is an effective tool for classifying land into various categories, such as rangeland, cultivated lands, and irrigated lands. Currently, the Service is using Landsat data on an experimental basis in conjunction with the traditional ground sources to estimate major crops in Arkansas, Colorado, Illinois, Iowa,

Kansas, Missouri, and Oklahoma. The Service plans to expand coverage to other states if funds can be obtained for such purposes. The Research Division Director told us that he believes Landsat is a valuable tool in crop estimating and the data provided often result in adjustments to estimates derived from traditional sources.

Soil Conservation Service

The Soil Conservation Service is responsible for developing and carrying out a national soil and water conservation program. Generally, the Service carries out its program through onsite, labor-intensive investigations by field office personnel. However, the Service uses Landsat on an experimental basis in four states as an aid to field personnel engaged in soil surveys and in two states as an aid in conducting land-cover studies. The Service makes soil surveys to identify and catalog specific types of soils throughout the nation. Landsat is used to identify soils with similar composition. Field personnel then take soil samples for analysis to determine whether the soils are identical. Land-cover studies involve identifying how the land is being used, such as for crops or as pasture, forest, or urban areas.

Although Landsat is currently only being used to a limited extent, the Service believes Landsat holds considerable promise in conducting soil surveys, resource inventories, and watershed analysis. A Service official told us that Landsat will become an important tool as high technology is substituted for the high cost of labor.

Agricultural Research Service

The Agricultural Research Service is the primary research arm of the Department of Agriculture. It uses Landsat to examine how remote sensing technology can be used to provide information about the ecological balance of agricultural areas. In addition, the Service is developing a computer program to eliminate atmospheric interference in Landsat images.

The Service conducts basic and applied research in support of the operational programs of other departmental agencies, such as the Foreign Agricultural Service and the Statistical Reporting Service. Examples of research efforts involving weather satellite data include

--determining water use rates by plants and crops,

--determining aridity indexes of land areas, and

--developing a computer program to eliminate cloud cover from satellite images.

A Service official told us that the Service plans to increase its use of Landsat data for assessing crop conditions and related variables. He also stated that weather satellite data hold considerable promise and that much of the Service's remote sensing research is evolving in that direction.

Forest Service

The Forest Service promotes and manages national forests. Its responsibilities include protecting and improving the quality of air, water, soil, and natural beauty of the forests and to assure balanced uses of forest products by private enterprise.

The Service currently uses Landsat satellite data on an experimental basis to inventory the renewable resources of Alaska and to conduct nationwide land-use surveys. Service officials believe that Landsat's potential is great because of the vast areas that can be covered at relatively low cost for mapping, surveying, and land management. For example, with Landsat data, nationwide, land-use surveys are now possible annually instead of every 10 years.

The Service uses the geostationary satellites' data collection system to collect data on wind, temperature, humidity, soil temperature, and moisture from its Remote Automated Weather Stations to prepare input for a national fire-rating system. The data collection system is less expensive than transmitting information by telephone line, the system it is replacing. The fire rating gives an indication of likely fire danger areas for planning purposes, i.e., for staging and moving people to fight fires. According to the Service's National Fire Planning Specialist, the Service is dependent on the Remote Automated Weather Stations' data for improving the accuracy of its fire danger model.

If the Service's use of Landsat in land management and resource assessment is successful, it plans to expand its use of satellite data into areas such as locating the outbreak of various forest pests and in mapping.

DEPARTMENT OF THE ARMY

Corps of Engineers (Civil Works)

The Corps of Engineers uses both the Landsat and weather satellite systems to support its natural disaster preparedness mission. Landsat data are used to, among other things,

--determine land cover as an aid in estimating the runoff potential of watersheds,

--produce economic studies of the impact different flood levels would have on cities and communities, and

--aid in planning mitigation efforts for presidentially declared major disaster areas.

According to Corps officials, these and other activities require the frequency and breadth of coverage which Landsat offers.

The Corps uses the geostationary satellites' data collection platforms and weather facsimile communication systems to obtain information on natural disasters. Satellite data are particularly important in flood control, which requires near real-time data.

DEPARTMENT OF COMMERCE

National Weather Service

The Department of Commerce's National Weather Service is the primary federal user of weather satellite data. The Service uses satellite data to provide general weather forecasts and warnings of severe weather such as hurricanes, tornadoes, and floods. According to Service officials, the weather satellites are particularly valuable for forecasting severe weather and for making long-term weather forecasts. The geostationary satellites are uniquely suited to detecting the formation of severe storms and hurricanes and tracking the movements of hurricanes through the Atlantic Ocean and coastal areas of the United States. The polar orbiting satellites are particularly useful in producing long-term U.S. forecasts because they provide data not otherwise available on the Pacific Ocean, where most of the nation's weather originates.

The Service uses two types of data from the geostationary satellites: visual images and quantitative environmental data. The visual images are supplied by two specialized instruments which remotely sense the earth's surface. The images have several uses, including locating actual or potential severe storms, following cloud motion, and determining wind speed and direction. Quantitative environmental data is provided by other sensors and by the geostationary satellites' data collection system which collects and relays environmental data obtained by remotely located platforms, such as seismology and tide guage platforms, data buoys, river and rain guages, aircraft, and automatic weather stations. For example, the seismology and tide guage platforms detect tsunamis (a very large ocean wave caused by an underwater earthquake or volcanic eruption) and provide early warning information to the Service's Tsunami Warning System Program. Data buoys provide measurements of ocean weather in areas away from coastal weather forecasting facilities or outside of shipping lanes. River and rain guages provide a near-instantaneous source of data on rainfall and runoff that is used in flood forecasting. A variety of other data platforms supply a continuous source of information to help the Service provide weather forecasts and severe weather warnings to the public.

The National Weather Service uses both quantitative data and image data from the polar-orbiting satellites. The quantitative data are used to improve the base for the Service's numerical weather prediction models. The data are obtained from a variety of sensors as well as through the data collection system. The data collection system is a French-produced system capable of collecting data from remotely located platforms and recording the location of those platforms at the time data were received from them. The system provides information such as the direction of ocean currents, rainfall amounts, surface winds and pressures, and subsurface ocean temperatures. Image data are obtained through other sensors and are used for a variety of purposes, such as

--producing global cloud maps to aid in analyzing weather patterns,

--analyzing ice conditions over ocean areas and the Great Lakes, and

--estimating snow pack in watersheds and predicting spring melt.

Environmental Research Laboratories

The Environmental Research Laboratories use weather satellites in various programs, such as analyzing convective (summertime) clouds and the precipitation processes in them, improving weather forecasting, studying cases of severe weather, monitoring solar variations not detectable from the ground, planning hurricane research flights, evaluating monsoons, studying ice conditions, and providing sea surface temperature maps to aid in understanding climate.

Most Environmental Research Laboratories expect to increase their use of satellite data, especially as technology advances. Some future uses include studying x-ray images of the sun to better forecast geomagnetic disturbances and constructing global wind circulation models.

DEPARTMENT OF ENERGY

The Department of Energy, through contracts with the National Laboratories and other research establishments, uses Landsat data in an increasing number of research applications. Specificaliy, Landsat data have been used to site energy-generating facilities, develop explorational techniques for energy resources, and characterize potential nuclear waste repository sites. Satellite images are used to locate geographical areas such as salt domes and granite formations suitable for dumping nuclear waste.

The Department of Energy will continue to perform research on the possible uses of Landsat in both energy and environmental research applications. An Energy official stated that a growth rate in the use of Landsat data of up to 20 percent per year for the next 5 years is possible. This estimate is dependent upon continuity and reliability in providing Landsat services.

ENVIRONMENTAL PROTECTION AGENCY

The Environmental Protection Agency has experimented with Landsat data to monitor air and water quality. For example, Landsat data have been used to classify land uses for monitoring air quality and to monitor the acidity of lakes. The Agency uses Landsat data experimentally because of resolution limitations. For small areas, the Agency believes that aerial photography is better than satellite data because it offers better resolution and can be obtained faster than satellite data. The Agency does not expect to increase its use of satellite data without improvement in the data resolution.

DEPARTMENT OF THE INTERIOR

United States Geological Survey

Current U.S. Geological Survey uses of Landsat data include (1) mapping of geologic structures to investigate likely occurrences of minerals and fossil fuels and to assess geological hazards, (2) geologic analysis in support of nuclear disposal program, (3) surface water inventories in the conterminous United States and Alaska, (4) national land-use/land-cover mapping, (5) preparing image maps in poorly mapped regions of Antarctica, the Middle East, and other regions to support international cooperative programs, (6) monitoring coastal shoreline changes, (7) detecting and monitoring oil slicks, (8) assessing and monitoring water quality and turbidity, (9) monitoring snow cover and melt in watersheds and hydroelectric dams for use in predicting runoff calculations, and (10) assessing the impact of floods and other natural disasters.

As uses of satellite data become more routine and integrated into the Geological Survey's programs, usage is expected to increase. With possible advancements in satellite sensor technology, telecommunications, computer processing technologies, and information extraction methods, it is expected that use of satellite data will increase many times over its present use, both operationally and in research.

Bureau of Land Management

The Bureau of Land Management uses both Landsat and weather satellite data in managing over 300 million acres of public lands. Weather satellite data are used in wildfire management for

lightning detection (lightning causes 60 percent of all major fires on public lands), mapping of types of burnable material, and calculating likely fire intensity and spread. These data help management make a decision on suppressing the fire or permitting it to burn itself out. Landsat data are also used in resource inventories (environmental assessments of oil and gas leases and mining), boundary location, trespass and easement determination (settlement of disputed boundaries, illegal easements, mining trespassers), geological mapping (glacier ice deposits, bedrock documentation, and minerals potential), and renewable resource condition assessment (monitoring rangeland for overgrazing, estimating numbers of grazing animals, determining whether to lease grazing lands).

Bureau officials expect to expand their use of satellite data in such areas as updating inventories, supporting evolving range-monitoring programs, creating geographic data bases for the Bureau's Alaska lands, monitoring dam safety, and collecting data for more accurate river and streamflow forecasts.

Bureau of Reclamation

The Bureau of Reclamation uses both weather satellite and Landsat data in (1) developing cloud seeding technology for increasing the nation's fresh water supplies, (2) surveying for wind energy sites, (3) investigating cathodic protection methods (pipe corrosion), (4) studying water evaporation on lakes, and (4) monitoring oil spill movements. In addition, the Bureau uses satellite data for (1) assessing uses of lands which may affect or change water resources in the area, analyzing geological structures (faults) which may affect the safety of a dam, canal, or other water structure, (2) measuring water quality and surface area of waters over large geographic areas, and (3) measuring the use of irrigation waters.

The Bureau expects its future uses of Landsat data to increase as satellite capabilities are developed and to continue ongoing programs in the remote sensing area.

Fish and Wildlife Service

The Fish and Wildlife Service uses satellites mostly as an auxilary data source for habitat mapping for national wildlife refuge planning, and for water resource project impact evaluations. For example, satellite data are used to monitor snow melt on Arctic goose breeding grounds to predict nesting success and regulate bird hunting. The Service's officials said that the agency will increase its use of satellites if improvements are made in resolution. Future uses include updating the National Wetlands inventory and continuing ongoing applications.

APPENDIX I

National Park Service

The National Park Service uses Landsat data to survey land cover, land uses, and geology for resource management and planning. For instance, one major application is for fire fuels modeling and fire behavior modeling. From these data, fire hazard maps are created and aid in determining whether a fire should be suppressed or allowed to burn. Landsat data are also used to determine how commercial activities, such as mining and animal grazing, affect land areas and to assess the habitat of endangered species, such as the grizzly bear. Other uses include evaluating the effects of man-made interference with water resources in the Everglades and for archeological investigations. In addition to continuing present programs, the Service expects increases in satellite use, including updating data bases on every large park every 10 to 15 years, monitoring how facilities (such as powerplants) in national parks use coal and how parks are affected by its use, and updating the quality of park maps to include natural history and trail guides.

Bureau of Indian Affairs

The Bureau of Indian Affairs uses Landsat data on an experimental basis to provide current land-use and land-cover information on Indian lands. The pilot project is to determine potential irrigable lands and to develop a rangeland trend and condition monitoring system. The Bureau expects its use of satellite data to increase in the future. In addition to land-use and land-cover applications, future uses of satellite data include determining the extent of natural resources on Indian lands, such as forests, rangeland, water, fish, wildlife, and minerals. The Bureau also plans a pilot study to determine the usefulness of using weather satellite data for monitoring and assessing drought conditions.

Bureau of Mines

The Bureau of Mines has used Landsat data on an experimental basis to detect the expansion of mines, monitor waste dumping to ensure proper disposal of waste from mines, and study the wilderness studies.

The Bureau has found Landsat especially useful in detecting faults which can cause mine cave-ins. Once faults are identified, the Bureau alerts mining companies so that steps can be taken to avoid mining accidents, loss of life, and production. Also, the Bureau provides information to the Mine Safety and Health Administration within the Department of Labor for use in safety and health enforcement activities.

Landsat use is expected to expand as new geographic areas are examined and other areas are reexamined to detect geological changes. Computerized evaluation of ground hazards will be a

APPENDIX I

major development. Instead of manually examining images to identify faults, computers will be used in the future to analyze Landsat data. Long-term goals include developing hazards maps in order to forecast potential problems in mined-out areas and monitoring waste piles and dams.

Office of Surface Mining
Reclamation and Enforcement

The Office of Surface Mining Reclamation and Enforcement uses Landsat data to make decisions on issuing mining permits. Landsat imagery is used to detect alluvial areas and determine the potential success of revegetation. Alluvial valley floors are geographical areas that are naturally watered with no need for irrigation and are protected to retain crop productivity. The Office expects its future use of Landsat to increase if the quality of data improves. For example, the Office is responsible for detecting, controlling, and extinguishing mine fires. Landsat's infrared capability could be used in this effort if the current image resolution were improved. Officials of the Office said that increased precision of Landsat images would make it possible to examine more land surface features, decreasing the need for more expensive data collection methods.

DEPARTMENT OF LABOR

Mine Safety and Health Administration

The Mine Safety and Health Administration uses remote sensing data to help prevent or reduce mine accidents and occupational diseases. Used in conjunction with high- and low-altitude aerial photography and topographic maps, Landsat can detect faults which can cause mine cave-ins. Landsat images provide views of a large area that cannot be duplicated with similar resolution by other means and are very useful in studying regional geography. The Administration has found Landsat images especially useful in detecting faults located in bedded deposits, such as coal mines,but not as useful in hard rock deposits. However, neither Landsat images nor aerial photography alone is capable of providing the entire condition of a geographic area and the Administration must verify this information with onsite observation. With the improvements made to Landsat through the addition of the thematic mapper, the Administration expects to become better at detecting faults.

The Administration is currently trying to update its Landsat images of current mining areas with the use of new products from Landsat 4. The end-product will be linear maps that can be used to design mine roof-control plans or highlight possible fault problems which mining companies can use to help decide where to place future mines.

Most mining areas have already been covered with Landsat imagery, and since geographical features do not change rapidly, future use of satellites will remain constant for the next 5 years. However, a project may be developed to aid the Bureau of Indian Affairs in monitoring mine waste impoundments and waste refuse piles. The project, if implemented, will be used to ensure that nonusable rock excavated from coal mines and deposited into bodies of water (mine waste impoundments) or accumulated into dry piles (refuse piles) do not endanger the safety of the surrounding community or environment.

DEPARTMENT OF TRANSPORTATION

Coast Guard

The Coast Guard uses weather satellites for (1) search and rescue--saving people and property distressed at sea, (2) marine environmental protection--minimizing the damage caused by pollutants, such as oil spills, (3) ice operations--operating the nation's icebreaking vessels for such purposes as facilitating maritime transportation and supporting U.S. polar installations, and (4) the International Ice Patrol--providing an iceberg warning service in the area of the Grand Banks of Newfoundland. It receives imagery and radio signals from the polar orbiting meteorological satellites and uses NOAA and Navy products, such as the Weekly Sea Current Chart, derived from the polar orbiting and geostationary weather satellites. In addition, the Coast Guard is participating in an international demonstration program to investigate using signals relayed from emergency distress radios at sea by the polar orbiting meteorological satellite. The Coast Guard has also used Landsat data in monitoring oil spills.

The Coast Guard expects the use of weather satellites for search and rescue satellite-aided tracking to become fully operational in the future. It also expects to use satellite data to monitor merchant vessel traffic and permit year-round trafficability in Western Arctic waters.

Federal Aviation Administration

The Federal Aviation Administration uses weather satellites in preparing preflight weather briefings to pilots and hazardous weather advisories to help route aircraft around a storm. National Weather Service meteorologists assigned to Federal Aviation Administration air route traffic control centers and Federal Aviation Administration personnel at flight service stations use images from the geostationary weather satellites to prepare the weather advisories and the weather briefings. Data from National Weather Service radar and other Weather Service products, such as maps of surface and upper level winds, are also used. The Federal Aviation Administration considers the satellite pictures to be critical to generating the weather advisories and briefings, believing that program objectives could not be achieved completely without the satellite data.

The Administration expects to continue its use of geostationary data but in the future will receive satellite data directly at its air route traffic control centers, rather than indirectly through the National Weather Service as is done now.

NATIONAL AERONAUTICS AND SPACE ADMINISTRATION

The National Aeronautics and Space Administration (NASA) uses the weather satellites and Landsat in its Earth Science and Applications Research program. NASA integrates the data from these operational systems and other sytems, such as its research and development satellites for its programs. NASA also flies experimental equipment on operational satellites, such as the thematic mapper on Landsat and search and rescue equipment on the most recent polar orbiting weather satellite. NASA works with other federal agencies, state governments, and foreign groups. For example, NASA, NOAA, and the Department of Agriculture have worked jointly on agricultural uses of remote sensing technology. NASA, NOAA, and the Departments of Defense (Air Force) and Transportation (Coast Guard) are working jointly on an international demonstration program for using a satellite system to aid in the search and rescue of aircraft and ships in distress. NASA also has separate agreements for joint participation by Canada and France in the program.

SMITHSONIAN INSTITUTION

The Smithsonian Institution uses weather satellite images to monitor volcanic activity. The Smithsonian created a Scientific Event Alert Network to serve the scientific community by gathering and disseminating information on volcanic activity, earthquakes, and meteorites. Information is gathered from a variety of sources, including scientists, government officials, interested amateurs, and the news media. Satellite images are acquired through interagency cooperation with NOAA. Satellite data add to both the number of eruptions reported and the quality of information about eruptions. For example, satellite data help Indonesia to monitor many dangerous volcanoes in a large, densely populated country with limited transportation and communications by giving a nearly instantaneous overview of explosive volcanoes.

CHAPTER TEN

MATERIALS PROCESSING IN SPACE*

By Marcia S. Smith
Specialist in Aerospace and Energy Systems

I. INTRODUCTION

Interest in the possibility of processing and manufacturing materials in the near zero gravity environment of space has existed for some time. The first space processing experiments were performed on three Apollo flights (14, 16 and 17), and continued on Skylab, the Apollo-Soyuz Test Project, and a number of sounding rocket launches in the SPAR (Space Processing Applications Rocket) program.

The concept of materials processing in space is based on the fact that in space, such processing can be accomplished without the force of gravity interfering with the procedure. Gravity is ever present on Earth, and its effects can be nullified for only a few seconds using drop towers or "zero-g" aircraft flights. The lack of gravity would allow production of new materials, such as mixtures of metals which can be made in space but not on Earth because the metals have different densities which cause them to settle into layers rather than remaining mixed. Without gravity, droplets of one metal will remain suspended in another of differing density for long periods of time.

Another potentially promising area is crystal growth. On Earth, the growth of homogenous crystals from solutions of melts is hindered by mixing effects caused by convection currents driven by gravity. In the absence of gravity, it has been shown both theoretically and experimentally that crystals can be grown with highly uniform compositions and properties.

NASA's Outlook for Space study concluded in 1976 that space processing and manufacturing were promising areas of endeavor for the future, involving use not only of the space shuttle/Spacelab combination, but of "longer duration stays in some sort of space station facility" as well.[1] NASA's Office of Space Transportation Systems subsequently contracted for two studies of the potential for space industrialization, including space manufacturing, in September 1976.

Both studies were completed in April 1978. The first, by Rockwell International, concerned identification of potential goals for space industrialization and development and assessment of evolutionary program options for realization of those goals, definition of program

*A number of terms are used to describe the production and/or processing of materials in space including materials processing, space processing and space manufacturing. Although there are shades of differences in meaning, the terms are used interchangeably in this chapter.

[1] NASA. Outlook for Space. Washington, NASA, 1976. NASA SP-386. p. 96.

Reproduced from Smith, Marcia S. Materials processing in space. In Congressional Research Service. United States Civilian Space Programs: 1958-1978; report prepared for the Subcommittee on Space Science and Applications of the Committee on Science and Technology, U.S. House of Representatives. Volume 1. Washington, For sale by the Supt. of Docs., G.P.O., 1981. p. 807-829.

support demands, evaluation and definition of leading program options, and development of recommendations for program implementation. The second study, performed by Science Applications, Inc., identified future opportunities for space industrialization, quantified their potential benefits, developed and analyzed evolutionary program options required to take advantage of these opportunities, and defined the framework of international governmental, industrial, legal and economic constraints within which space industrialization would evolve. The results of these studies are discussed as appropriate in the sections which follow.

II. CONGRESSIONAL INTEREST

Congress has shown considerable interest in the potential of space manufacturing, both through hearings and the introduction of bills to stimulate private sector involvement in such research.

The Senate Committee on Aeronautical and Space Sciences (which was abolished in 1976 and its functions transferred to the Commerce, Science and Transportation Committee) and the House Science and Technology Committee (formerly Committee on Science and Astronautics) have each held hearings either on space manufacturing specifically, or more generally on the topics of space industrialization or future space programs. Hearings of special note include: Senate—*Space Shuttle Payloads* (Part 2, October 31, 1973), and *Space Processing* (June 17, 1976); House—*Future Space Programs 1975* (July 22, 23, 24, 29, 30, 1975), *Space Industrialization* (September 29, 1977), and *Future Space Programs* (January 24, 25, 26, 1978). All these documents are available from the Government Printing Office.

Legislation has also been introduced bearing on the potential of space manufacturing. Specific legislation to create a Space Industrialization Corporation to provide a funding scheme for meritorious projects has been introduced in the House,[2] and the space policy bills introduced in the Senate [3] include language to promote greater industry involvement in space exploitation, especially space manufacturing.

III. ORGANIZATION WITHIN NASA

In the early part of 1969, NASA established a Materials Sciences and Manufacturing in Space program under the Advanced Missions Program Office of the Office of Manned Space Flight. At the end of the Apollo program, the Office of Manned Space Flight divested itself of all responsibility for payloads to concentrate on development and operation of the space shuttle, and the materials sciences program was therefore transferred to the newly created Office of Applications on April 1, 1973. At this time, its name was changed to the Space Processing Program and placed under the Special Programs Division of the Office of Applications.

---

[2] H.R. 2337, introduced on Feb. 22, 1979 by Congressman Don Fuqua, Chairman of the House Committee on Science and Technology.

[3] S. 212, introduced by Senator Harrison Schmitt, ranking minority member of the Senate Commerce, Science and Transportation Subcommittee on Science, Technology and Space on Jan. 24, 1979; S. 244, introduced by Senator Adlai Stevenson III, chairman of that subcommittee, on Jan. 29, 1979.

In January, 1978, the Office of Applications was renamed the Office of Space and Terrestrial Applications and the space processing program was raised to a division level and its title changed once again, this time to the Materials Processing Space Division.

IV. RESULTS FROM PAST EXPERIMENTS

There already have been several experiments concerning materials processing in space both in the United States and abroad. In the United States, experiments were conducted during the Apollo, Skylab and Apollo-Soyuz programs, and using sounding rockets (the SPAR program). The European Space Agency (ESA) has conducted several sounding rocket experiments for space processing and appear very interested in continuing such experiments on the space shuttle. Germany, a member of ESA and largest single contributor to Spacelab, is carrying on a substantial unilateral materials processing in space program. The Soviet Union has conducted a wide variety of space processing experiments, first in 1969 on Soyuz 6 (welding experiments), and again on their manned space station series, Salyut. Recent Russian manned space flights to Salyut 6 have increased their experience with space processing substantially, leading NASA associate administrator for space and terrestrial applications, Anthony Calio, to report to Congress in March 1979 that "The Soviets now have a data base that will not be available in the U.S. program until 1982." [4] The scope of this study, however, does not permit detailed examination of these foreign programs.

A. Apollo 14, 16 and 17

Three U.S. lunar Apollo flights carried early space processing experiments: Apollo 14 (launched January 31, 1971), Apollo 16 (launched April 16, 1972), and Apollo 17 (launched December 7, 1972). The following information on the experiments and their results is taken primarily from the *Apollo Program Summary Report* published by NASA's Johnson Space Center in 1975 (JSC–09423).

1. Composite Casting

Apollo 14 carried composite casting experiments. Composite casting refers to the casting of a material from a mixture of a liquid matrix and solid particles. The Apollo experiments were designed to demonstrate whether or not mixtures of materials having different specific gravities would remain mixed in the liquid state and during freezing in the low gravity environment of a spacecraft. Eighteen samples were provided for the Apollo 14 flight (although only eleven were processed due to time constraints) consisting of fibers, microspheres and gas in an indium-bismuth matrix, or paraffin and sodium-acetate trihydrate.[5]

Sealed metal capsules containing these materials were inserted into an electric furance, heated for a prescribed time and then cooled by placing the capsule onto a heat sink device (some samples were also

[4] Anthony Calio. Prepared Statement to Senate Commerce, Science and Transportation Subcommittee on Science, Technology and Space. Mar. 2, 1979, p. 30.
[5] G. Seibert. Material Sciences in Space. Pt. 1: Review of Space Experiments to Date. ESA Journal, vol. 2, 1978: 8.

shaken to mix the materials). The capsules processed in space were compared with mixtures processed on Earth under otherwise similar conditions. Although a limited range of materials were studied under non-instrumented conditions which were not closely controlled, the demonstrations showed that unique material structures were produced.

2. Heat Flow and Convection

Apollo 14 and Apollo 17 carried three heat flow and convection experiments: a flow pattern experiment to investigate convection caused by surface tension gradients resulting from heating a thin layer of liquid; a radial heating experiment to obtain information on heat flow in a confined gas under low-gravity conditions; and a lineal (or zonal) heating experiment to investigate heat transfer in confined liquids in low gravity.

a. Flow Pattern.—On Apollo 14, the flow pattern cell consisted of a shallow aluminum dish uniformly heated from the bottom to establish a thermal gradient across a thin layer of heavy oil (Krytox) which contained aluminum powder to allow flow patterns to be observed and recorded by a 16 millimeter camera operating at one frame per second. The Apollo 17 experiment was the same except that baffles were added around the periphery of the pan to maintain the liquid level at a uniform depth (in one experiment at 2 millimeters, in another at 4 millimeters).

The Apollo 14 experiment demonstrated conclusively that surface tension alone, without gravity, could generate cellular convection. Apollo 17 confirmed these results, and demonstrated that convection at the 4 millimeter depth showed more regular and larger cells than at the 2 millimeter depth. Convection in 2 millimeter depth solution was less orderly and symmetrical than patterns obtained with ground-based unit, but were more orderly and symmetrical than observed with the Apollo 14 experiment, where a constant depth could not be maintained because of wetting of the cell liner.

b. Radial and Lineal Heating.—The radial heating experiments consisted of a cylindrical dish containing either carbon dioxide gas (Apollo 14) or argon gas (Apollo 17) covered with a glass window coated with a liquid crystal material that changed color when heated. The cell was divided into quadrants with each sector sensitive to different temperature ranges. Changing color patterns, denoting temperature distribution, were recorded by camera.

The lineal heating experiment on Apollo 14 consisted of two glass tubes with cylindrical heating elements surrounding the center of the tubes, with one tube containing distilled water, and the other a 20% sugar solution to produce a fluid with approximately twice the viscosity of pure water. Temperature changes were sensed by liquid crystal strips located along the central axes and walls of the tubes. Color patterns were monitored as heat flowed from the centrally heated region to the ends of the tubes. On Apollo 17, a single glass tube containing Krytox oil was used, and the liquid was heated by a disc heater at one end of the tube rather than a centrally located heater. Temperature changes again were monitored by liquid-crystal strips immersed in the fluid.

In these experiments, scientists expected that conduction and radiation would be the only modes of heat transfer because the driving force for convection would be absent, but the Apollo 14 experimental data showed that temperature changes were occurring faster than could be attributed to conduction and radiation alone. The Apollo 17 results observed no significant convection, and the conclusion was drawn that the Apollo 14 results were caused by motions of the heat flow and convection unit and spacecraft, not by a new, unknown process.

3. Fluid Electrophoresis.—Electrophoresis, a method of separating molecules in a solution by applying an electrical current, is considered a potentially promising area of space processing because of its possible application to separating and purifying valuable biological products, especially isoenzymes.

The electrophoresis experiment on Apollo 14 consisted of an electric system, three electrophoresis cells, and a system to circulate the electrolyte through the cells, all contained in a metal case. Each cell was filled with a different solution: a red and blue dye mixture, hemoglobin, and salmon sperm deoxyribonucleic acid (DNA) in an aqueous solution of boric acid. The red and blue dyes separated as expected, but no action was observed in the hemoglobin or DNA tubes; on return to Earth it was found that the hemoglobin and DNA had been consumed by bacterial action. The resolution of the dye separation was found to be much better in space than on Earth in similar apparatus, and the shape and sharpness of the advancing boundary of separated material was improved in space by the lack of remixing due to convection currents.

Following on the Apollo 14 failures with hemoglobin and DNA, the Apollo 16 experiments used two different particle sizes of polystyrene latex (0.2 and 0.8 micrometer diameter) to simulate the size and density of living cells without the problem of bacterial attack. One cell contained a mixture of the two sizes, one contained only large particles and the third contained only small particles. Electro-osmosis (the movement of liquid with respect to a fixed solid as a result of an applied electric field) occurred resulting in bullet shaped samples. Electro-osmosis had been predicted and the experiment designed to minimize the effect of this occurrence, but its presence, coupled with the formation of large bubbles near the positive electrode, reduced the effectiveness of the demonstration. Data did clearly show the stability of the bands which developed and the sharpness of the particle fronts. The 0.2 and 0.8 micrometer particles combined in one of the cells did not separate into distinct bands as had been expected, but the bands were distorted into the shape of two bullet-shaped surfaces nested together. The leading band in the two cells containing the 0.2/0.8 micrometer mix and only the 0.8 micrometer particles was significantly more pointed than in the cell containing only 0.2 micrometer particles.

B. Skylab

The U.S. space station Skylab hosted three three-man crews from 1973 to 1974 that performed twenty-one materials processing experiments, shown in Table 10-1 (there were fourteen experiments, seven

of which were performed twice). Three experiments were performed by the Skylab 2 crew (the first manned mission) in the Materials Processing Facility (designated M 512), while a fourth experiment had to be omitted at the last minute to make room for repair equipment for the workshop (which had been damaged during launch, see Chapter Six). This experiment would have investigated gallium arsenide crystal growth.

The remaining eleven experiments were performed in the Multipurpose Furnace System (M 518), with all eleven performed once by the Skylab 3 crew and seven repeated by Skylab 4. (Originally, the Skylab 3 crew was not scheduled to perform any materials processing experiments, but they had enough available time that they were allowed to go ahead with the Multipurpose Furnace Experiments.)[6]

Results from the Skylab experiments have been published in *Proceedings, Third Space Processing Symposium: Skylab Results* (Volumes 1 and 2, NASA, Marshall Space Flight Center, June 1974 M–74–5), which served as the primary source for information in this section.

1. M 512 and M 518 Processing Facilities

The M 512 processing facility was located in the Multiple Docking Adapter and was comprised of a work chamber, a control panel, an electron beam gun, and storage boxes for experiment modules and an-

[6] Michael L. Yaffee. Skylab Science Data Found Promising. Aviation Week and Space Technology, Feb. 18, 1974 : 56.

cillary equipment. It was mounted on a honeycomb panel which also served as a heat radiator.

The work chamber could be vented to space, thereby providing an evacuated chamber when required. The chamber was illuminated and had windows so the experiments could be observed while in process by the crew and photographed by a fixed motion picture camera. The work chamber included a mount which accommodated each experiment in turn and doubled as a heat sink with a predetermined and calibrated thermal impedance. An electric connector was located near the mount for power and signals for all experiments except those using the M 518 furnace.

The electron beam gun, with an output of 2 kilowatts, was used to melt specimens in the Metals Melting and Sphere Forming experiments. The gun was powered by batteries so was independent of Skylab's power system.

The M 518 Multipurpose Furnace was installed in the M 512 chember when in use. It could produce temperatures as high as 1000°C, could hold the temperature constant for preset lengths of time for specific experiments, and cool at constant programmed rates, resulting in a predictable but not constant rate of solidification of the molten samples. It required 200 watts of power which were drawn from the spacecraft power supply.

2. Experiments With the M 512 Material Processing Facility

a. M 551: Metal Melting Experiment.—This experiment used the electron beam gun for cut-through, full and partial penetration melts of aluminum, stainless steel and tantalum to study the effects that occur during welding in space. Welding in space may be important if large space structures are to be constructed in the future. The experiment proved that such welding is feasible, and found that the welds made in space contained small, equiaxed grains compared with large, elongated grains in samples processed under otherwise similar conditions on Earth.

b. M 552: Exothermic Brazing.—This experiment investigated the potential of brazing as a method of joining tubes for assembly, repair and maintenance in space, and to study the spreading, mixing and capillary action of molten braze material in near zero gravity. Four specimens were processed, each consisting of a tube, sleeve, inserts (spacers) and silver-copper-lithium braze rings. Two of the samples contained pure nickel tubes and sleeves, while the other were type 304 L stainless steel. A radioactive isotope (110-Silver) was added to one of the nickel specimens to assist in analysis of capillary flow. The experiment was very successful, producing excellent braze joints with less porosity and finer microstructure than could be achieved on Earth.

c. M 553: Sphere Forming Experiment.—To study the effects of weightlessness on containerless solidification processes, twenty samples of pure nickel and three nickel alloys (containing copper, tin, or silver) were mounted on a disk which revolved in front of the electron beam gun. The materials melted and then resolidified one by one. Some separated from the disk and resolidified while free floating in the chamber. The solidified samples provided a detailed record of the freezing process, and two of the nickel alloy samples formed large internal

voids by an as yet unexplained spontaneous vaporization process during the initial stages of cooling.

3. Experiments Using the M 518 Multipurpose Furnace System

a. M 556: Crystal Growth by Vapor Transport.—Experiment M 556 was designed to study the quality of crystals grown by chemical vapor transport in the near zero gravity environment of Skylab compared with Earth-grown crystals. Six transport experiments employing different concentrations of transport agent (germanium tetraiodide) and two temperature gradients were performed on germanium selenide and germanium telluride crystals which are compound semiconductors. The experiments showed that there is considerable improvement with the space processed crystals in terms of surface perfection, crystalline homogeneity and defect density. Scientists also observed greater mass transport rates than had been expected (in measuring the amount of crystal material deposited from the vapor in a given time at different pressures, the space experiment deposited up to ten times as much material as had been predicted) indicating that existing transport models are incomplete. The experiment showed that larger and more perfect crystals could be grown in space (in the case of germanium selenide, one crystal grew six times larger than expected).

b. M 557: Immiscible Alloy Composition.—This experiment was designed to study the effects of near zero gravity on the processing of immiscible materials. Three cartridges, each containing three separate experiment ampoules, were processed simultaneously and compared with similar specimens processed in one-g. The first two cartridges (containing ampoules of gold-germanium, and lead-zinc-antimony) were processed in the isothermal section of the furnace while the third (lead-tin-indium) was processed in the gradient region. In all of the cases, the space processed specimens showed better homogenization and microstructural appearances than in prior Earth-based experiments. The electronic behavior of the space processed specimens was comparable to that of the one-g samples, however.

c. M 558: Radioactive Tracer Diffusion.—Experiment M 558 was designed to detect any disturbances of pure diffusion behavior that might be caused by spacecraft motion. Radioactive atoms of zinc–65 were allowed to diffuse through rods of zinc metal melted in the Multipurpose Furnace. Ground processed samples are mixed by convection, so that the radioactive zinc is evenly distributed through the sample. In the space experiment, the distribution accurately reproduced mathematical predictions based on the theory of pure diffusion.

d. M 559: Influence of Gravity-Free Solidification on Microsegregation.—Three germanium crystals, doped with gallium, antimony or boron, were melted and directionally resolidified using the Multipurpose Furnace. Results from the gallium-doped germanium crystal showed that microsegregation in space is reduced by two to five-fold in the bulk and eight-fold near the surface, while macrosegregation is reduced six-fold in the bulk. Improved homogeneity can be exploited to produce solid state electronic devices with more predictable and uniform performance.

e. M 560: Seeded, Containerless Solidification of Indium Antimonide.—Indium antimonide crystals were contained in a cylinder such

that one end was held in a closely fitting container and the other extended into an enlarged cavity. The cavity was heated while the other end of the cylinder remained cool. A drop of molten material formed on the end of each sample in its cavity and was retained by surface tension and adhesion. The sample was then solidified directionally by lowering the cavity temperature and letting heat leak away through the remaining solid part of the crystal. It had been expected that the crystals would retain the shape of the molten drops from which they solidified, but they did not. The reasons are not well understood, but it could only have occurred if the diameter of the molten drop remained larger than the diameter of the solid. In addition, approximately 30% of the surface consisted of flat facets oriented in planes defined by the underlying crystal structure, and the number of imperfections in the crystals decreased steadily as growth proceeded.

The experiment demonstrated that "forces intrinsic to the solidification process itself determine the shape of a single crystal solidified from a melt under zero-g. Moreover, these forces apparently favor the formation of crystals with flat facets and few imperfections—both very desirable characteristics in crystals for electronics, because most solid-state devices employ flat wafers and suffer degradation in performance from crystal imperfections." [7]

f. M561: Preparation of Silicon Carbide Whisker Reinforced Silver Composite Material in Weightless Environment.—This Japanese experiment was designed to produce void free matrices of silver, reinforced with oriented whiskers of silicon carbide. The results indicated the influences of buoyancy and thermal convection in the samples processed on the ground versus those processed in space where those forces do not exist. The space grown crystals showed a uniform distribution of hardness values and did not have any floating whiskers, although voids were not completely eliminated from the samples because the springs provided to keep them under pressure weakened when the samples were heated.

g. M 562: Steady State Growth and Segregation Under Zero Gravity: Indium Antimonide.—Similar to experiment M 559, M 562 used three indium antimonide crystals (one intrinsic, one doped with tin, and the third doped with tellurium) to study steady state diffusion during crystal growth in near zero gravity. Approximately half of each sample was melted and then resolidified directionally, beginning from the interface between the melt and the original crystal. The region near the initial regrowth interface revealed no dopant inhomogeneties across the entire diameter of the crystal, showing the advantage of performing such processes in space. The experiment identified the origin of segregation discontinuities associated with facet growth, the mode of nucleation and propagation of rotational twin boundaries, and the specific effect of mechanical-shock perturbations on segregation.

h. M 563: Directional Solidification of Indium Antimonide and Gallium Antimonide Alloys.—This experiment was designed to study how weightlessness affects directional solidification of binary semiconductor alloys, and to grow mixed crystals of indium antimonide

[7] James H. Bredt and Brian O. Montgomery. New Challenges for Industry. Astronautics and Aeronautics, May 1975 : 28.

and gallium antimonide from a convectionless melt to improve perfection. By varying the proportions in such alloys, their semiconductor properties can be adjusted to values optimized for various application. In this experiment, however, conditions for the growth of single crystals were not achieved and the materials consequently did not solidify as homogenous alloys.

i. M 564: Halide Eutectic Growth.—Experiment M 564 was designed to produce oriented rod structures of sodium fluoride in a sodium chloride-sodium fluoride eutectic. The end product was expected to have fiber-optic properties useful for infrared image transmission if continuous fibers could be produced. Continuous fibers were produced in the space based samples (compared to discontinuous fibers in the Earth-processed samples), and this was attributed to the absence of convection currents in the liquid during solidification.

j. M. 565: Silver Samples Melted in Space.—This Belgian experiment was designed to study the behavior of porous material when melted and resolidified in near zero gravity. Very fine porous structures are desired for filtration and absorption. Two types of samples were used: perforated discs and a fibre compact. Most of the original porosity disappeared during the melting stage, which scientists believe could be avoided by using different heating and pressure conditions or using samples with closed pores in future experiments.

k. M 566: Copper-Aluminum Eutectic.—Portions of three copper-aluminum specimens were melted and resolidified, resulting in data which showed that the aligned eutectic in space grown specimens had fewer defects: an improvement of 12% in average defect spacing and a decrease in 20% in the average fault density.

C. Apollo-Soyuz Test Project

Although the focus of the 1975 Apollo-Soyuz Test Project was to demonstrate the possibility of linking two spaceships from different nations in space (the U.S. Apollo with the Russian Soyuz, see Chapter Six), the mission also carried a variety of scientific experiments. Two biological materials processing experiments were conducted, along with seven U.S. solid materials processing experiments. Summaries of the ASTP experiments and their results have been published in detail in *Apollo-Soyuz Test Project: Summary Science Report* (NASA SP–412, 1977) from which the following information is summarized.

1. Biological Materials Processing (Electrophoresis)

Two electrophoresis experiments were conducted on ASTP, the first (Electrophoresis Technology Experiment) was American, while the second (Electrophoresis Experiment) was German.

The U.S. experiment was based on previous experiments conducted on Apollo 14 and 16 and designed to demonstrate the static column (zonal) method of electrophoresis. A closed tube filled with buffer solution was used with an electric field aligned along the tube into which the sample was introduced as a frozen pellet near one end. After a period of time to allow the sample pellet to melt, the electric field was turned on and the sample was transported along the tube to separate its faster and slower moving components. At the end of the separation run, the solution in the entire tube was frozen to immobilize the

sample fractions and returned to Earth for analysis. Five different mixtures were processed: mixture of rabbit, human and horse fixed red blood cells; human peripheral blood lymphocytes; human fetal kidney cells; fixed rabbit and human red blood cells; and fresh rabbit and human red blood cells. The last two were processed by isotachophoresis, a variant of electrophoresis in which different buffer solutions are used ahead of and behind the sample in the tube.

The experiment was designed to demonstrate requirements for application of electrophoresis on future space flights: preservation of cell viability before processing; processing; and preservation of viability after processing.

Zonal electrophoresis was accomplished by separating the fixed red blood cells species from their mixture, although the lympocytes did not electrophorese successfully (possibly because the cells lost viability due to pH fluctuations). The isotachophoresis experiments were only partially successful because only frontal boundaries developed. The kidney cell separation experiments, which were important to scientists interested in increasing supplies of urokinase [8] were successful.

The German experiment was designed to demonstrate the free-flow method of electrophoresis in a near zero gravity environment. In this procedure, the buffer solution flows continuously through a rectangular duct and the cell mixture is continuously inserted into the flow. Rather than being aligned in the same direction of the flow, in this method the electric field is perpendicular to flow so that the cells separate laterally as they pass downstream. Four mixtures were processed: rat bone marrow cells; fixed rabbit and human red blood cells; rat spleen cells; and rat lymph node cells with human red blood cells as markers. Separated streams were detected by a photo-optical system and data stored on magnetic tape.

The photo-optical detection system developed an anomaly during flight, so that the ultraviolet lamps in the detector system were 42 percent brighter than they were supposed to be, resulting in reduced data. Despite this development, results from the German experiments showed that electrophoresis was accomplished with a tenfold increase in the throughput rate and with at least as sharp cell separation as is achievable on Earth.

2. Solid Materials Processing Experiments

Six U.S. high temperature and one low temperature solid materials processing experiments were performed on ASTP. The six high temperature experiments involved the use of a Multipurpose Electric Furnace, an advanced version of the furnace used on the Skylab workshop. Improvements included capability of providing higher temperatures (nominally 1423°K) with no increase in the power requirement, and the ability to allow controlled, variable rate cooldown, including addition of a helium injection rapid cooldown system which reduced the time needed to cool the samples from 20 hours to three. Each experiment involved a set of three stainless steel cartridges, with each cartridge containing from one to three samples. All three cartridges were processed at the same time.

a. Surface Tension Induced Convection.—This experiment was designed to detect possible convection due to surface tension gradients

[8] Urokinase is an enzyme which can dissolve blood clots.

resulting from compositional gradients in a sample of pure lead interfaced to an alloy of lead and 0.05 atomic percent gold. Two diffusion temperatures were used (923°K and 723°K), and results showed that incomplete mixing occurred in a pattern not explainable by diffusion. Possible causes for this include small amounts of convection induced by spacecraft motion, fluid motions caused by the density change of lead during freezing, or segregation effects due to gold's differing solubilities in liquid and solid lead.

b. Monotectic and Syntectic Alloys.—In this experiment two materials (aluminum antimonide and lead-zinc) were melted and solidified to observe the effects of these processes in near-zero gravity. Aluminum antimonide has potential application as a solar cell material, but difficulties have been encountered in producing the material on Earth because of difficulty in achieving chemical homogeneity and because the material is highly reactive with moisture. The latter was thought to be the result of secondary phases which occur in Earth-processing, and data from the space processing experiments showed considerably less of the undesirable secondary phase. Major improvements in macroscopic and microscopic homogeneity were also achieved.

The lead-zinc experiment was designed to show phase segregation effects in near-zero gravity conditions. The two elements are immiscible in the liquid state and separate rapidly upon melting because of their large density differences. It was expected that they could be successfully kept mixed in space. The experiment produced unexpected results however. The materials separated into two macroscopic regions—one zinc, and one lead with a zinc bubble in it. No difficulties were encountered in processing the materials, with requisite temperatures achieved as scheduled, leading scientists to conclude that the temperature needed for the alloying to occur must be higher than what had been previously thought.

c. Interface Marking in Crystals.—The third high temperature solid materials processing experiment was designed to explore crystal growth and impurity segregation characteristics in a directionally solidifying material. Gallium-doped germanium single crystals were partially melted and then regrown while current pulses were transmitted across the travelling solid/melt interface at four second intervals to provide identifiable marks enabling determination of growth rates. The rate of crystal growth was the same for the space processed sample as for those processed under similar temperature conditions on Earth. The segregation results showed that the dopant concentration increased as the interface travelled over approximately 1.5 centimeters, but with continuing growth, the dopant concentration decreased, rather than achieving a steady-state value. The Principal Investigator for the experiments concluded that this unexpected behavior was a result of the geometry of the growth system, rather than a result of the near zero gravity environment.

d. Zero-G Processing of Magnets.—The fourth experiment involved investigation of the potential for enhancing magnetic coercive strength of two materials: an alloy of manganese and bismuth, and an alloy of copper, cobalt and cerium. The manganese-bismuth alloy contained very fine needles of the magnetic compound MnBi in a bismuth metal matrix and achieved significantly improved coercive strength at low

temperatures. The cobalt-cerium alloy reacted with its containing crucible, so experimental results were inconclusive.

e. Crystal Growth from Vapor Phase.—Following on the Skylab experiments with crystal growth from the vapor phase involving germanium selenide and germanium telluride using germanium tetraiodide as a transport agent, this ASTP experiment extended the investigations to new materials. Three experiments were performed using three chemical compounds, two transport agents, and one inert gas. Results showed improvement of the space grown crystals over Earth-grown crystals in terms of chemical and crystalline homogeneity, surface morphology, and bulk perfection. Measurements of the rate of crystal growth confirmed results of the Skylab experiments.

f. Halide Eutectic Growth.—Another follow-on to Skylab investigations, this experiment was designed to grow continuous fibers of lithium floride in a matrix of sodium chloride to demonstrate the advantages of space processing for producing infrared-transmitting fiber optics. The experiment was successful, producing lithium fluoride crystals with improved transmittance over a wider wavelength range with better image quality than had been obtained on Earth.

g. Crystal Growth.—This was the one low temperature experiment (it did not involve use of the multipurpose furnace), and was designed to demonstrate the growth of crystals by diffusion of appropriate reactant toward each other through pure water at ambient spacecraft cabin temperature. On Earth, the most successful growth process based on this principle involves using a gel to support the growing crystals and suppress convection. This method results in reduced diffusion rates and multiple nucleation of crystals in the gel, which usually prevents the growth of large single crystals. Without the force of gravity, it was reasoned that the gel would not be required to support the growing crystals, so pure water was used instead. Three crystals were grown: calcium tartrate, calcium carbonate, and lead sulfide. The crystals obtained were of a size and quality comparable to the best grown on Earth in the same length of time; the best results were obtained with calcium tartrate and the least successful with lead sulfide.

D. Space Processing Applications Rockets (SPAR)

The SPAR program began in 1975 and through the end of 1978 had launched a total of five Black Brant VC sounding rockets from the White Sands Missile Range in New Mexico. Each flight provides approximately five minutes of weightlessness (see Chapter Five for a discussion of sounding rockets). Four more SPAR flights are planned, two in 1979 and two in 1980. SPAR flights are designed to provide basic information about materials processing during the hiatus in U.S. manned space flight.

SPAR I, launched on December 11, 1975, carried nine experiments, all of which functioned correctly, entitled: space solidification of Pb-Sb (lead antimonide) eutectic; feasibility of producing closed-cell metal foams in a zero-gravity environment from sputter-deposited insert gas-bearing metals and alloys; uniform dispersions of crystallization processing; liquid mixing; direct observation of solidification

as a function of gravity levels; casting dispersion-strengthened composites at zero gravity; thermal migration of bubbles and their interaction with modification interfaces; contained polycrystalline solidification in low gravity; and preparation of a special alloy under zero gravity for magnetic hard superconductors.

The six experiments on SPAR II, launched May 17, 1976, also worked correctly. Three of the experiments were repeats from SPAR I (space solification of lead antimonide eutectic; feasibility of producing closed cell metal foams in a zero gravity environment from sputter deposited inert gas-bearing metals and alloys; casting dispersion strengthened composites at zero gravity) and there were three new experiments (direct observation of dendrite remelting and macrosegregation in casting; agglomeration in immisible liquids; and solidification behavior on aluminum-indium alloys under zero gravity conditions.)

On December 14, 1976, SPAR III was launched and continued the success of the series with all five experiments functioning properly: liquid mixing; interaction of bubbles with solidification interfaces; epitaxial growth of single crystal film; containerless processing of beryllium; and contact and coalescence of viscous bodies.

In 1977, the SPAR program encountered its first failure. At the beginning of the program it had been decided to launch SPAR missions at the rate of two to three per year. Although all experiments on the first three flights functioned correctly, by the time of the fourth launch on June 21, 1977, problems developed and none of the four experiments worked. (The four experiments carried on SPAR IV which did not function were: Uniform Dispersion by Crystallization Processing, Contained Polycrystalline Solidification in Low-g, Containerless Processing of Amorphous Ferromagnetic Materials, and Containerless Processing Technology.) NASA associate administrator for space and terrestrial applications, Anthony Calio, reported to Congress in September 1978 that these anomalies were the result of experiment and equipment developers taking technical risks because they were constrained to flight dates selected in the early stages of their work.[9] As a result, the fifth SPAR flight, originally scheduled for launch in the fall of 1977, was postponed for almost a year so that no experiment would be flown until its technical and scientific readiness had been verified.

SPAR V was flown on September 11, 1978 carrying four experiments, all of which functioned correctly. SPAR V carried the following experiments (two of which were repeated from SPAR IV): Uniform Dispersion by Crystallization Processing, Dendrite Remelting and Macrosegregation, Agglomeration in Immiscible Liquids, and Contained Polycrystalline Solidification in Low-g.

V. FUTURE PROGRAMS

SPAR flights are expected to continue through 1980, after which a Materials Experiment Assembly (MEA) will be used on early shuttle

[9] Dr. Anthony Calio. U.S. Congress. House. Committee on Science and Technology. Subcommittee on Space Science and Applications. 1980 NASA Authorization (Program Review). Hearings. 95th Congress, 2d session, Sept. 25, 26, 27, 1978. Washington, U.S. Government Printing Office, 1978. p. 176.

flights to perform similar experiments. MEA is a self contained experimental package with its own power source and heat rejection capability so that only simple interfaces with the shuttle will be necessary. SPAR payload apparatus will be installed in the MEA to perform the experiments. NASA has identified several areas for early materials processing studies, as shown in Table 10–2.

Rockwell International performed a study under contract to NASA's Office of Space Transportation Systems from September 1976 through April 1978 to identify potential goals for space industrialization in general, including the development and assessment of evolutionary program options for realizing those goals and definition of program support demands, evaluation and definition of leading program options, and development of recommendations for program implementation.[10]

The report concluded that there are a number of attractive opportunities in the area of manufacturing products in space, shown in Table 10–3. To accomplish the goals set forth in the report, Rockwell proposes that the space shuttle be used to continue experiments which will prove basic space processing concepts, followed by free-flying Space Processing Facilities (SPF). Each SPF would consist of a solar cell power array and a modified external tank from the shuttle (see Chapter Seven) left in orbit by an earlier shuttle mission. The SPF itself would be automated, but would require servicing by the shuttle.

Weighing 68,000 kilograms, the SPF would have a continuous power level of 300 kilowatts available from nickel-hydrogen batteries (charged by solar cell array.) The space shuttle would make regular visits to the SPF, providing raw materials for the manufacturing operations and retrieving materials already processed. The facility would be used primarily for zone refining and crystal growth, and would have fiifteen furnaces producing 750 boules of finished product every sixty days, or 4,500 boules per year weighing 21,150 kilograms. Rockwell suggests deployment of ten SPF's, requiring thirty shuttle flights per year for servicing.[11]

Ultimately, if materials processing in space proves economically viable, longer duration manned or unmanned facilities could be constructed. One such concept now being discussed is a Space Manufacturing Facility involving permanent manned space habitats for a variety of uses, including space manufacturing. Dr. Gerard O'Neill of Princeton University has been a leading advocate of such facilities placed at one of the Lagrange coordinates where the gravitational forces of the Earth and Moon balance each other out. He has specifically recommended that such a space manufacturing facility be used to manufacture satellite power stations for placement in geosynchronous Earth orbit for electric power production and transmission in Earth (see Chapter Fifteen).

TABLE 10-2

NASA CANDIDATE AREAS FOR EARLY MATERIALS PROCESSING IN SPACE EXPERIMENTS *

AREA OF RESEARCH	TASK	APPLICATION
Infrared Detector Materials	Study problems associated with compositional control required to satisfy advanced remote sensing needs.	Infrared imaging systems for military surveillance, earth sensing applications, law enforcement, scientific instrumentation, medical diagnosis.
Inertial Confinement Fusion Targets	Study problems associated with geometrical control to produce more efficient implosion conditions in large size, hydrogen filled glass shells.	Short range applications in fusion research for weapons and power generation programs. Long range possibilities for energy production.
Containerless Processing	Development of fundamental physical understanding of positionirg force fields and the utility for new materials processing.	Scientific studies of reactive materials, development of glass shell production methods, control of purity in glasses.
Floating Zone Experiments	Study melt surface and flows related to surface tension gradients in the floating zone configuration.	Separate and quantify fluid flow effects in earth-based floating zone processes as well as study new configurations for space experiments.
Heat Pipe Technology	Development of high temperature heat pipes to provide advanced control capabilities of the thermal environment of materials processing in space.	Establish controlled isothermal and very high temperature-gradient capabilities to grow solid-solution semiconductor crystals from the melt under stabilizing conditions.
Space Vacuum Research	Identification of extra high vacuum characteristics associated with orbiting molecular wake shield environment.	Extend range of important experimental parameters to perform vacuum science experiments and also to identify utility of this new environment for materials processing.
Bioprocessing Studies	Study of heat and mass transport problems limiting separation and synthesis of biomaterials in earth-based technologies.	Improve efficiency of ground-based bioprocessing methods and identify candidate techniques which take unique advantage of weightless conditions.

VI. VIABILITY OF PROGRAM

The question of whether a materials processing in space program is viable depends on a variety of factors, including whether industry will be interested in the processes or materials so produced, and whether such materials will be economic for use by the general public.

A. INDUSTRY INTEREST

The ultimate commercial viability of materials processing in space may depend on whether industry is interested either in the processes themselves or the materials manufactured in space. To date, little re-

search appears to have been done to determine just exactly what industrial interest in this area might be, in the United States or abroad.

One survey was conducted by Arthur M. Dula, a patent attorney, and Ann Roebke, an industrial anthropologist in 1977 which surveyed 378 companies selected from the Fortune 500 list of American industries and the Fortune 300 list of American service industries. Twenty percent of the companies responded, while another seven percent stated either that their company had no connection with the space program or had a policy against responding to questionnaires. The survey showed that although 30% of those responding were aware of and interested in communications satellites (see Volume II) and satellite power stations (see Chapter Fifteen), less than a tenth of them were interested in materials processing in space such as pharmaceuticals, ultra-pure chemicals or crystal growth.[12]

Dula and Roebke found that a large majority of respondents did not consider tax treatment of space investment expenses and manufacturing profit important in determining whether their company would participate in space industrialization, although the issue of patent rights was considered extremely important. The survey results showed that a large majority of the respondents would either not consider or adversely consider space research if the Government retained patent rights and granted the company only royalty free licenses. Conversely, the respondents indicated that if the Government waived claims to patent rights on space-related discoveries, they would be encouraged towards participating in space industrialization.

Science Applications Inc. (SAI) performed a study under contract to NASA from September 1976 through April 1978 to identify future opportunities for space industrialization, quantify their potential benefits, develop and analyze evolutionary program options required to take advantage of these opportunities, and to define the framework of international governmental, industrial, legal and economic constraints within which space industrialization must evolve.

In considering the economic feasibility of space manufacturing, SAI contacted nine non-aerospace product manufacturers who, according to SAI, had little or no previous contact with space processing or manufacturing concepts: Arthur D. Little, Inc.; Ball Brothers Research Corporation; Shell Oil Company; Talley Industries, Inc.; U.S. Polymeric Corporation; Arvin Industries, Inc.; Olin Chemicals Corporation; Union Carbide Corporation; and a ninth contact who was an individual investor and past company president. Each company was provided with general information about space processing and manufacturing and the study SAI was performing for NASA, and then queried about their perspective of the market for space products.[13]

Survey results showed that the "domestic industrial world is not aware of the real import of the NASA Space Shuttle or of NASA activities in Space Industrialization." Specific comments from the in-

[13] Science Applications Inc. Space Industrialization. Huntsville, Ala., Apr. 15. 1978. Volumes 1–4. SAI–79–602–HU. SAI–79–603–HU. SAI–79–604–HU. and SAI–79–605–HU. NASA Contract NAS8–32197. The information for this section is taken from Volume 3—Space Industrialization: World and Domestic Implications. pp. 70–75.

dustrial companies included: "The products are poorly defined at this time"; "The markets are too indefinite yet"; "The risks are very large relative to the capital outlay required"; and "The return on investment period is too long."

Despite these rather negative views, the respondents state that they thought their companies would become involved in space industrialization if their competitors did. They also commented that the prospects for space industrialization were "interesting," and that an appropriate risk-reducing or risk-sharing policy on the part of the Federal Government would stimulate private industrial interest. Better communication between NASA and themselves was cited as an area where work was needed, and the respondents felt that it was NASA's responsibility to establish improved communication since it had the service to sell to them.

SAI concluded that to generate industry interest in space manufacturing, NASA should: (1) establish better communications with domestic industry by means of an interface organization, a space industrialization newsletter with background and current information, and continual feedback from domestic industry; (2) establish a means of sharing costs and risks of space industrialization research and development; (3) reduce space transportation cost; and (4) make space industrialization research relevant to potential products.[14]

In 1977, the President of Battelle Memorial Institute, Dr. Sherwood Fawcett, suggested one method for establishing more government/industry cooperation in the field of materials processing in space. Emphasizing that before industry can invest stockholder's money in a new product or procedure, firm Government policies on costs, liability and proprietary rights are needed. Dr. Fawcett suggested establishment of a Space Industrialization Trust Fund by the Federal Government.[15]

As proposed by Dr. Fawcett, the Trust Fund would sponsor research and development programs to be performed by or for a U.S. company. The company would certify that a project would lead to a new product or process which would utilize the space environment, have a potential of generating new income and public benefits through its utilization, and whose results would be used by the company if the work was successful. All information and intellectual property generated would be protected and licensed by the Government with payment of royalities to the Trust Fund up to the cost of the project plus interest. This money would then go to finance other projects. According to Fawcett, the Trust Fund concept would provide "an enormous incentive and stimulant to private industry. The public is benefited because the 'winners' pay back with interest and the 'losers' provide information which enable a future winner to be made."[16]

NASA has established a Commercial Space Processing Development Office at Marshall Space Flight Center to study legal, institutional and economic issues involved in private sector space processing activities.

B. Economic Viability

Assuming that industry does exhibit an interest in material processing in space, the question of whether products so produced will be economically viable on Earth will still remain an issue. It has been reported [17] that NASA, Dow Chemical Company and Polysciences Inc. have reached an agreement on marketing latex spheres produced on the first materials processing shuttle flight in the early 1980's (these spheres are now used primarily for calibrating electron microscopes, although larger sizes which can be made in space could be used in sizing blood particles and aiding the treatment of certain lesions of the eye). The companies would reimburse NASA for the manufacturing services and market the spheres themselves to determine how such products might fare in actual market demonstration.

The National Academy of Sciences' report on the scientific and technological aspects of materials processing in space (discussed in the next section) states that the study group did not discover "any examples of economically justifiable processes for producing materials in space and [the Committee] recommends that this area of material technology not be emphasized in NASA's program." [18]

By contrast, the study discussed in the previous section by Science Applications, Inc. (SAI) showed a large market for some space produced materials. SAI noted, however, that "It is important to realize that these analyses were made in order to get some data on what the future potential might be. As this implies, the expected answer was anticipated to be nothing more than a "ballpark" number. Thus no claims are made relative to the viability of any specific products called out here . . . With a sufficient reduction in launch costs to Low Earth Orbit (LEO), say $5 to $50 per pound, it is quite probable that these market projections will (in the aggregate) prove much too conservative." [19]

In testimony before the House Science and Technology Committee in January 1978, G. Harry Stine, a member of the study team, revealed some of the study's conclusions.[20] While cautioning that there were many unknown variables which might change the forecasts included in the report, Mr. Stine reported that, for example, the potential market for space-produced perishable cutting tools in the year 2000 was estimated to range from $280 million to $2.8 billion. For space-produced bearing materials, he reported an estimated market of from $69 million to $690 million in the year 2000.

These attempts to quantify commercial prospects, and therefore economic viability, for materials processing in space must be considered speculative in nature since there are so many unknowns, especially economically, for the United States between now and the year 2000.

C. National Academy of Sciences Report

In the fall of 1978, the National Academy of Sciences' Space Applications Board released a study entitled "Materials Processing in Space," prepared under contract to NASA, which investigated materials processing in space from a science and technology viewpoint.[21]

1. Need for Preflight Investigations

The study emphasized that space based procedures must rely on data from previously conducted Earth-based experiments, and that without strong basic knowledge of the behavior of materials on the surface of the planet, little new will be learned in space. The question of whether NASA has provided adequate support for preflight investigations had been raised previously by space processing researchers.[22]

While criticizing the early NASA space processing program for poorly conceived and designed experiments from which weak conclusions were drawn and, in some cases, over-publicized, the report stated that "there is opportunity for meaningful science and technology developed from experiment in space *provided that problems proposed for investigation in space have from the outset a sound base in terrestrial science or technology and that the proposed experiments address scientific or technical problems and are not motivated primarily to take advantage of flight opportunities or capability of space facilities.*" (page 5, emphasis theirs).

2. Advantages of Near Zero Gravity Environment

The Academy Committee looked at all the variables which it could identify in space and found that the only advantage to materials processing in space was the near zero gravity condition,[23] concluding that other aspects of the space environment (temperature, ambient vacuum and radiation) either had no effect on materials or their effects could be duplicated on Earth. The Committee identified four areas in which a near-zero gravity environment would be useful in experimentation: the possibility of reducing or practically eliminating buoyancy-driven natural convection for substantial periods of time; the possibility of testing experimentally the basic assumptions necessary in theoretical models of systems in which complicated patterns of fluid density variation are inherent; the possibility of reducing or practically eliminating the settling of particles for substantial periods of time; and the possibility of levitating and isolating larger samples for containerless processing.

To gain a perspective on the overall viability of a materials processing in space program, the Committee chose one technology, that of growing semiconductor crystals in space for commercial use, for detailed examination. As outlined in a previous section of this chapter, a number of crystal growth experiments had been performed during

---

[21] Originally the Academy had planned to do two materials processing in space studies, the first on the scientific and technological aspects, the second looking at the commercial aspects of the field (proprietary rights, etc.). As of December 1980, the second study on commercial aspects had been deferred indefinitely.

[22] NASA Seeks Industry Space Processors. Aviation Week and Space Technology, Jan. 26, 1976, p. 55.

[23] Some gravitational acceleration is caused by human movement within a spacecraft, movement caused by thrusters used to maintain correct orbital attitude, and the like. Therefore in an earth-orbital space station one encounters "near-zero gravity" rather than zero gravity.

the Skylab missions. Although the Committee agreed that the results obtained on Skylab showing that crystals of superior characteristics could be produced in space were valid, the Committee stated that "these results are not sufficient to permit concluding whether growth in space of crystals for commercial electronic devices is or is not viable." (page 37) The materials used in the Skylab vapor-growth experiments (germanium-selenide (GeSe) and germanium-telluride (GeTe) are not expected to be used in practical electronic devices, according to the report, nor is the growth technique used expected to be used for growing those materials that do have significant practical applications. Another material, indium antimonide (InSb), was also considered commercially unimportant by the Committee since it is used only in a small number of specialized infrared detectors, and the growth method (directional solidification in a closed tube) is not used for production of commercial electronic devices. Therefore the Committee concluded that it was "impossible to extrapolate the results of the InSb, GeSe, or GeTe experiments to specific materials or processes used or planned for use commercially or to predict any specific advantages of processing those materials in a low-g environment." (page 38)

In the early 1970's, space-based electrophoresis was represented as being of considerable potential benefit in the production of vaccines,[24] although more recently focus has shifted to the production of isoenzymes such as urokinase. This field received very little support from the Academy, based on the thesis that electrophoresis studies on the ground did not yet provide a solid basis for investigations in near zero gravity. Calling the results from the Skylab and ASTP experiments "tenuous," the report suggested that further funding be spent on identifying what role gravity (and other parameters) plays in the electrophoretic process through ground-based studies. "In terms of what is now known, the Committee concludes that there is no pressing need for an enlarged trial of electrophoresis in space." (page 30)

3. Organizational Recommendations

The Committee also issued recommendations on the organizational structure of a materials processing in space program. It suggested that the program be conducted in two phases. During Phase One, which would last for about five years, NASA should make every effort to include other agencies in the planning of appropriate experimental programs which would clearly delineate the potentials and limitations of materials processing in space, and provide NASA with necessary experience in developing facilities of maximum value to the scientific and engineering communities.

Phase Two would see NASA as operator of the space shuttle as a national facility for materials processing, with industry and universities providing requisite funding for experiments rather than NASA. This phase would necessarily develop only if materials processing in space proved to be viable during Phase One, and in the Committee's view, if adequate funding is not supplied by the outside community, Phase Two should be discontinued.

In response to the Academy's recommendation, NASA established a Commercial Space Processing Development Office at its Marshall

[24] For example, see David Keller's statement in: U.S. Congress. Senate. Committee on Aeronautical and Space Sciences. Space Shuttle Payloads, part 2. Hearing, 93d Congress, 1st session, Oct. 31, 1973. Washington, U.S. Government Printing Office, 1973. pp. 91–101.

Space Flight Center to conduct studies of institutional, legal and economic issues involved in private sector space processing activities, and to handle negotiations with any company that might express interest in long-range joint undertakings with NASA.[25]

4. General Conclusions of the NAS/SAB Study

The overall conclusions of the Committee were that the instances in which the low-gravity environment of space is likely to be important for materials processing in space will be few and specific, and that it found no examples of economically justifiable processes for producing materials in space. The Committee recommended that NASA not emphasize materials production (as opposed to processing aspects of the program). The Committee also emphasized that "NASA must keep in mind that one of the proper roles is the development and operation of singular facilities in response to and not independent of the scientific and technological community."

Aviation Week & Space Technology, March 14, 1983

Space Station Pivotal in NASA Future

By Craig Covault

Washington—National Aeronautics and Space Administration space station studies have matured to a point where findings and decisions made over the next eight months could affect the character of the agency for the next 10-20 years. NASA managers forecast station development would substantially change the character of U. S. space operations and the structure of NASA itself.

NASA would like to start a $5-6-billion station development program with significant funding beginning in Fiscal 1986 and continuing at $1 billion a year until an initial operating capability is reached about 1991.

Although participating in detailed station justification studies, the Reagan Administration has not committed to station support. Presidential Science Adviser George Keyworth has characterized the station concept as an "unfortunate step backwards." These indicators do not mean the concept is on a dead end street, however, because many factors, including strong political issues, will be part of the approaching station decision.

The structure of NASA in the era of station development also will be an issue. Even with $1 billion a year in station development funds, many agency managers believe NASA would still be underutilized. Some managers also believe the only way out of this excess overhead is to close one or two NASA centers and possibly consolidate shuttle mission control activity at Kennedy Space Center. A space station may not require a Johnson Space Center massive control center—the concept is for it to handle most of its control activities right on board.

Space station factors important to near-term decision making and long-term NASA planning are:

- Distributed system.
- Justification base.
- Man-tended satellites and platforms.
- Manned science operations.
- Unlikely Defense Dept. participation.
- Commercial participation.
- Science and applications users.
- Corporate reluctance.
- New start timing.
- Station task force strategy.

Space station task force studies show a U. S. station will not look like Skylab or the Soviet Salyut but will be a set of space-based systems, both manned and unmanned. In all cases the "station" would be evolutionary with a small, habitable core functioning as a manned operations base to service spacecraft on platforms distributed either near or some distance away from the habitable section.

No dominant user or justification has been found to warrant a large U. S. station system. The justification must come from an aggregate of users, NASA station task force studies show.

Station task force data also show that the ability of manned crews to tend satellites and platforms within reach of the habital section offers benefits in retrieving commercial products, adjusting instrumentation and replenishing consumables. The "man-tended" approach for a broad series of spacecraft is a key station justification in current studies. It enhances numerous existing missions and enables others to be done for the first time.

Use of man to perform extensive onboard scientific work in a space station has been found to be a minimal justification for most station activity. For life sciences work and some technology work, a manned presence is necessary, but for most science the man can be located re-

motely. "It would be a bit of a swindle to try and persuade people not familiar with the program that science really requires man to be around all of the time," Stephen S. Holt, science representative on the station task force, said. "Telepresence, with man in the loop but not on site, will do fine in many areas."

The outlook is poor for extensive Defense Dept. participation during early station evolution because the department, although actively studying military station uses, has not found high-priority uses for a permanently manned facility and has serious concerns about survivability.

Space task force and contractor study data show both aerospace and nonaerospace industry interest in a space station system, however. There is fairly high interest in a station-based industrial research laboratory that could be used by a number of companies. At least one aerospace company is interested in funding its own station compartment for proprietary work, station task force managers said. Commercial interest, however, is no more dominant than that of any other potential user groups. The companies do not want to put big money up front when station risk is high. They are more interested in paying for facility use, once the government puts facilities in place.

Use of a station as a base from which to tend and replenish large free-flying observatories or Earth-observing platforms has emerged as a strong concept in space station task force studies. Which disciplines benefit first will depend upon whether equatorial or polar basing is selected initially. The plan is to evolve into operations in both orbits.

Some managers believe station user requirements and interests have been hard to assess because the aerospace companies have not yet put their best options on the table for fear of tipping their hand at a point so early in the program that competing companies would benefit from the information. The same reluctance has been part of the reasoning of companies wishing to exploit space for commercial purposes, some managers believe.

Although NASA does not plan to request significant station development money until Fiscal 1986, it is possible a formal space station line item could appear in the Fiscal 1985 budget. In addition, the White House Senior Interagency Group (SIG) for Space has a station working group, and data acquired by that body could lead to an Administration statement on the station within the next year.

Office of Management and Budget remains unconvinced a station is a good idea, however. One OMB view is the most NASA will receive is approval to move ahead with unmanned platforms to be serviced by the shuttle, but not a permanently manned facility.

An approach much different from the space shuttle definition 15 years ago is

being used by NASA station managers. Instead of designing the vehicle and telling the user community to find ways to exploit it, the station approach is to define across-the-board requirements, let those requirements determine the function of individual station elements and then have those functions influence how the hardware is built.

The approach has been difficult to grasp by NASA and contractor managers more familiar with hardware. Part of the requirements data base is being assembled by eight aerospace corporate studies. During their midterm review last January, some companies were graded poorly for trying to tailor requirements too much to fit what they thought would be an appropriate operating mode. The studies are being completed and data compiled by review groups and the Defense Dept.

Next month the station task force will take all those requirements and at either the NASA Langley or Wallops Center will meet for about two weeks merging these requirements into one or two sets of time-phased mission requirements.

"The reason we want to do that is to give us some feel for what are the design drivers for the early and late phases of a potential space station," John Hodge, director of the station task force, said.

"The crucial point is that the design will be incremental, but each increment has to serve a major useful purpose," Daniel H. Herman, deputy to Hodge on the task force, said. "In April we will determine what crucial increments will yield what station functions."

As the mission requirement sets are about to be completed, the NASA centers are just completing their first round of work on about 30 of nearly 300 potential trade studies identifying the work needed to be done to reach certain system goals like electrical power in a space station.

With the mission set and trade study data, the station task force hopes by midsummer to make preliminary conclusions on the functional pieces of the station that will be needed first and how they will fit together. This will not relate to a single habitable facility but to the station system as a whole, manned and unmanned elements.

The station task force describes the definition of capability of each element and its relationship to other elements as "station system architecture."

The first significant version of station architecture is expected by this summer. Hodge hopes that by year's end the station task force will be close to determining

formal U.S. station architecture. Even with those data, the planning will still not be at the design phase. Since the important requirements that will govern the nature of a U.S. station system will remain embedded as individual elements in the trade studies until after the April session, it is not now possible to identify what the system will look like or its major uses.

Hardware Concept

Engineers and planners are used to working the opposite way, with a hardware concept much earlier. In this case that approach will not work.

"It is very difficult to hold these people back," Hodge said.

The definition is proceeding under NASA headquarters control, not at either the Johnson or Marhsall centers, NASA's principal manned flight focal points. This has caused consternation among some managers, especially at Johnson.

Johnson's original space operations center concept involved more of the traditional approach toward system design with a significant amount of early hardware concepts. The station task force has strived, however, to avoid station configurations at this planning stage. Task force members believe the important contribution Johnson has made to the planning effort is a concept of station operations much broader than more tradational Skylab/Salyut station operations concepts.

Marshall also focused on configurations, stressing the use of existing hardware in dispersed platforms operating in the vicinity of a habital module. Marshall's contribution has therefore been the "distributed system" concept.

The distributed system has resulted in use of a concept called "energy proximity," meaning a part of the station operations separate from the habitable module but in an orbit easy to reach from the station base area.

System Development

The distributed system and energy proximity concept will require NASA to develop a teleoperator maneuvering system, a moderately sized propulsion stage that can carry hardware or crewmen to different elements of the distributed system. The device would not be as large as the orbital transfer vehicle eventually necessary to make longer trips between widely separated orbits, or from low orbits to geosynchronous orbit.

Since the teleoperator maneuvering system would be useful for a wide range of shuttle applications in addition to station work, NASA expects to develop it separately from the space station budget.

The agency determined two or three years ago that a true national station concept required operations in both polar and equatorial orbits. Defense intelligence and Earth applications payloads need to fly in polar orbits while most science, commercial and transportation-oriented space missions need the more easily reached equatorial orbits.

A question to be addressed soon, important to the station and NASA's long-range future, is whether to go polar or equatorial with the initial station elements. Station task force members will take three options into the April meetings and hope the requirements data will direct them toward one mission model area. The options are:

- **Equatorial first**—One option would establish operations at about 28.5 deg. equatorial inclination followed by establishment of polar orbit operations. Once station-type operations were in both orbits, a large orbital transfer vehicle (OTV) would be developed as the third sequential element in this operation.

- **Higher-priority OTV**—The second option is establishment of the station first in equatorial orbit, followed by OTV development. Polar operations would follow third. The sooner the OTV is developed, the sooner manned geosynchronous orbit and station-supported planetary missions can be started.

- **Polar priority**—The third option is to develop polar orbit space station facilities first, then equatorial orbit facilities followed by the OTV. This option would emphasize defense intelligence and a wide range of Earth applications missions first.

The concept of satellite servicing and man-tended systems would come much faster with an equatorial system. Space Telescope, for example, would probably be serviced in space over a 20-year period instead of being returned to Earth every

Workforce to Grow

Stevenage, England—British Aerospace Dynamics expects to increase its space-oriented work force from the present 1,600 employees to 1,800 by the end of 1983 and to 2,000 in three to five years to handle the increasing amount of space-related work it is receiving.

The work force already has grown from 1,400 since 1982.

Additional manufacturing and development space is being acquired in Stevenage, although the exact size of the facilities expansion has not yet been determined.

Work is done here and at the company's factory in Bristol. Company officials said there are no plans to expand to other sites. Economics, according to the officials, dictate that as much work as possible be done at existing sites.

five years for maintenance as currently planned.

The current Earth-return maintenance requires two dedicated shuttle flights for each ground servicing. In addition, large telescopes starting out as shuttle payloads would be left in orbit as servicable facilities. The solar optical telescope is a good example.

These are the types of missions helped by a station. A mission type made possible in the first place by such permanent orbital support would be large advanced facilities, such as infrared telescopes that need cryogenic cooling.

The Infrared Astronomical Satellite (IRAS) mission now making new discoveries in deep space has only about a one-year cryogenic helium supply before the spacecraft will cease operations (AWAST Feb. 28 , p. 21). With this rapid cryogenic depletion rate, such spacecraft can never perform the role of ongoing observatory, providing both cost and science benefits. If serviced in space, however, long-life systems can be designed and flown for years at a time.

Spacecraft Refueling

The only serviceable spacecraft currently operating in polar orbit are U. S. Air Force digital imaging reconnaissance spacecraft and an occasional film-based imaging reconnaissance spacecraft. It might be useful to refuel the digital spacecraft and refuel and reload film on the film satellites in the future.

"Basically if we go polar orbit as the first option, it will be an entirely new ball game. There are few serviceable spacecraft in polar," Holt said. "But if you go polar there are a number of Earth and atmospheric viewing instruments that would make a lot of sense being put together as one giant coordinated observatory."

One such concept has been designated System-Z. System-Z would be a large platform that contains a whole battery of Earth viewing instruments on a large serviceable platform. The concept is to have digital-imaging, microwave, radar, oceanographic, atmospheric and other instruments all taking coordinated data. The data products would then flow to a central distribution facility on Earth where multiple-user communities could procure the data.

"The whole emphasis in polar is a large platform instead of a lot of little free flyers being serviced in the way they would at 28.5 deg. orbit inclination," Holt said. In polar orbit the relatively small number of platforms would carry a large number of instruments to be serviced, as opposed to the equatorial orbit, where a relatively large number of spacecraft could be serviced, each carrying more specialized instruments.

Station Support

NASA station planners believe both polar and equatorial orbits will eventually support station activity. The question is where will it be established first.

Other factors that contractors and other groups studying station requirements have been asked to include in their assessments are:

- **Inheritance**—Any station must be capable of allowing a smooth inheritance of hardware from existing programs such as Spacelab.
- **Manned requirements**—Science and research areas that require direct manned participation, such as life sciences and materials processing, must have near-continuous availability of man, not just visitation by man.
- **Technical intervention**—Most disciplines benefit more from manned technical intervention for servicing and construction than they do from manned science interaction.
- **Technical capability**—Manned technical intervention need only be occasional, such as once every several months or years, but the intervention period itself could be lengthy, extending several days or weeks, such as for construction, assembly and checkout of new hardware.
- **Existing spacecraft servicing**—Several new spacecraft coming on line such as Space Telescope, Gamma Ray Observatory and the Advanced X-ray Astronomical Telescope will be available as a "cluster" of spacecraft in need of service at about 28.5-deg. inclination.
- **Platforms**—Free-flying platforms associated with the station are planned for early development but are not yet defined as to how large or what discipline they will involve. Their development will be somewhat contingent upon what type of continuous manned station activity NASA is able to achieve early in the development of the new national space facility. □

NASA Wants a Space Station

Proposals range from a multibillion dollar space city to a low-budget platform; but what do the users want?

"We have a highway to space!" astronaut Thomas K. Mattingly proclaimed after the fourth and final test flight of the space shuttle Columbia. And now that the shuttle is officially ready for use, he added, "we need to build the city"—a permanent space station in low earth orbit.

Mattingly is not alone in that sentiment. The National Aeronautics and Space Administration (NASA) as a whole wants that space station very badly. It would be the agency's next major mission, the heir to Apollo and the shuttle. NASA administrator James M. Beggs suggested it as such in his confirmation hearings last year, and since then has been touting the idea at every opportunity. The agency fought for, and obtained, favorable wording for the idea in the Reagan Administration's new space policy (*Science*, 23 July, p. 331). In May a ten-member task force was organized at NASA headquarters to coordinate further planning. And next year the agency hopes to include more than $10 million for space station development in the fiscal year 1984 budget, which goes to Congress in January. NASA estimates the station will ultimately cost some $3 billion to $5 billion, with the initial modules reaching orbit about 1990.

NASA's fervor for the station stems in part from institutional need. Without some kind of new mission the agency sees itself degenerating into a kind of high-tech trucking company, with nothing much to do but launch payloads for other people. But it also stems from a vision of the space station as the logical next step after the shuttle. Agency officials are fond of pointing out that the space station idea came first. The shuttle was conceived in the 1960's simply as a cheaper way of getting up there and back. Now that the shuttle is operational, says deputy administrator Hans Mark, it is time to go back and finish the original plan.

Unfortunately for NASA, however, it is hard to imagine a worse economic climate for proposing a multibillion-dollar space city—especially since a great many people still see every space endeavor in the image of Apollo: massively expensive projects pursued for little else but national glory and NASA's continued existence. Senator William Proxmire gave Beggs a lecture on the subject in hearings last May: "I am concerned that [the space station] will proceed regardless of the real need for such a program because your agency needs it more than the country needs it."

Among scientists, meanwhile, there is a widespread fear that the space station would be another shuttle, with delays and cost overruns that once again savage NASA's science and applications programs. As one high-ranking House staffer puts it, "I think there will be support for the space station as a long-range goal—if NASA doesn't have to give up everything else to get it."

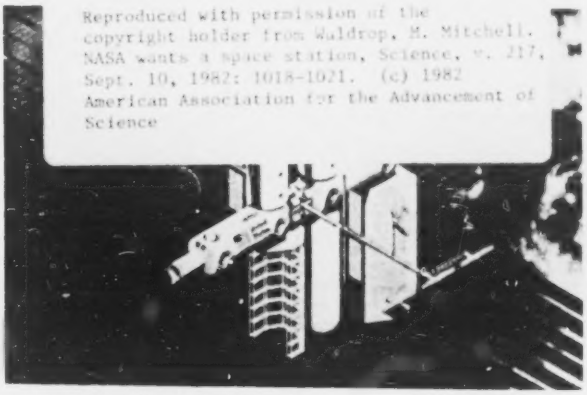
On the other hand, many of these skeptics concede that a modest platform, focused on specific user needs, might prove very useful. It could serve as a research platform in fields such as astronomy, materials science, and remote sensing. With further development it could also serve as a transportation hub for moving communications facilities into geosynchronous orbit, or for launching a new generation of planetary spacecraft. Presidential science adviser George A. Keyworth, who has been highly skeptical of the more ambitious space station concepts, told *Science* that such a low-key, step-by-step approach has a reasonable chance of White House approval.

The question, then, is not whether a space station per se is worth having. A space station should be a tool, not an end in itself. The real question is whether that tool is worth the cost.

The answer seems to be "Yes," although that judgment depends on just how well NASA fits the station hardware to the needs of users. Unfortunately, NASA generated considerable confusion on the matter during the last year, with different segments of the agency advocating very different things.

Broadly speaking, there are two points of view. On the one hand, there are the veteran engineers who remember the glory days of Apollo. They stress the importance of manned operations in space. Their ideas for a space station are epitomized in the Space Operations Center, or SOC, a conceptual design produced by the Johnson Space Center in Houston, Texas. The SOC features habitat and workshop modules for 9 to 12

Reproduced with permission of the copyright holder from Waldrop, M. Mitchell. NASA wants a space station, Science, v. 217, Sept. 10, 1982: 1018-1021. (c) 1982 American Association for the Advancement of Science



The Space Operations Center concept

The design includes solar panels, habitat and workshop modules, construction booms, fuel tanks, and spacecraft hangars. All the modules would be brought up by the shuttle and assembled in space.

0036-8075/82/0910-1018$01.00/0 Copyright © 1982 AAAS

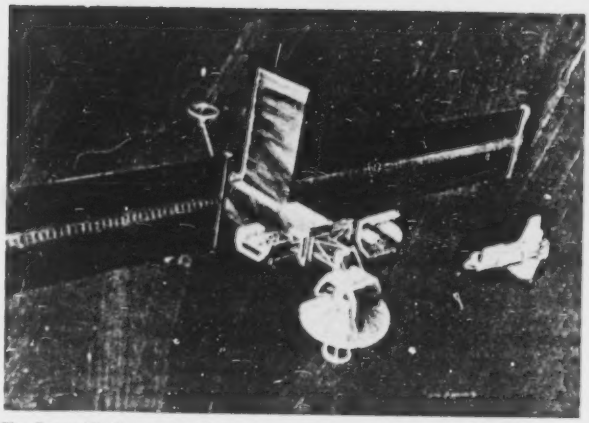
people, construction booms for assembly of antennas and other large space structures, and fuel tanks for a separate Orbital Transfer Vehicle that would take cargo brought up to the station by the shuttle and ferry it into the 35,900-kilometer geosynchronous orbit. SOC would cost about $8 billion over 10 years.

For a while, the Johnson public relations team managed to convince a lot of people that SOC *was* the space station, even though NASA was actually nowhere near a final design. In fact, top agency officials have all but disowned SOC. Space assembly and orbital transfer might be crucial in the 1990's, but in the current economic climate SOC's $8-billion price tag was only giving ammunition to critics of the station. Besides, the emphasis on SOC was obscuring the fact that there are other ways of building a station, ways much more congenial to cost-conscious Washington.

The most prominent example was the Space Platform design produced by Johnson's rivals at Marshall Space Flight Center in Huntsville, Alabama. The platform epitomized the task-oriented point of view of NASA's scientists and applications people. In its simplest, unmanned form, it would be little more than a set of solar panels for power, some internal electronics, and a number of sockets for instrument pallets taken right out of the shuttle payload bay. Manned modules and construction equipment could be added later, if needed. The Huntsville group estimated that the first space platform would cost about $750 million, with replicas costing another $400 million apiece. While such platforms could hardly be called cheap, the Huntsville planners argued that the price would be low enough for NASA to contemplate building several and specializing each to a different purpose.

Back at NASA headquarters, however, Beggs and his associates saw little chance of getting their space station unless they could resolve the confusion and come up with something all the potential users could support. Both the Marshall and the Johnson plans were too specialized, it was felt. Thus, both designs were scrapped, and in May the Space Station Task Force was formed to reconcile the disparate points of view into an all-NASA design.

Task force leader John Hodge seems well aware of NASA's oft-criticized tendency to plunge ahead with hardware development before it thinks much about the users. That impulse prevailed in the shuttle program, he points out, and as a result the agency spent the late 1970's in an embarrassing scramble for customers.



The Space Platform concept

Shown here with the space shuttle in the far background, the platform would essentially just provide power and stabilization for instruments mounted in pallets brought up in the shuttle's payload bay.

It is a prime source of apprehension and skepticism about the station. "So we're trying to take an entirely different approach," he says. "We're saying, To hell with the configurations, what are the requirements over the next 25 years?"

Thus, Hodge is asking eight aerospace companies to take a fresh look at the scientific, commercial, and military missions for a station. Only after the appropriate missions are identified will each of the eight draw up new conceptual designs. "Then you compare them and try to take the best from each," he says. By mid-1983 the results should be in hand and the agency should be ready to begin technology development and trade-off studies.

Some user needs are already fairly clear. A good example is space astronomy. During the past decade, enormous strides have been taken with short-lived satellites such as Uhuru, Einstein, and the Solar Maximum Mission, and the astronomers are hungry for more. Space Telescope, due for launch in 1985, will allow them to study how faint, distant galaxies and quasars began forming in the aftermath of the Big Bang. Solar Optical Telescope (SOT) will ride in the shuttle bay to image the fine structure of flares and sunspots—structure obscured by the atmosphere, but crucial for understanding solar activity, the solar wind, and their impact on the earth. SIRTF, the cryogenically cooled Shuttle Infrared Telescope Facility, will use its freedom from infrared-absorbing water vapor to peer into molecular clouds, where stars are being born, and into the core of our galaxy, where there may be a supermassive black hole (*Science*, 21 May, p. 838).

When the National Academy of Sciences recently made its recommendations on astronomy's needs for the 1980's [the "Field Committee" report (*Science*, 16 April, p. 282)], well over half the programs involved new instruments in space. At the same time, the report strongly endorsed the use of a space platform for astronomy.

"There are few, if any, astronomical missions that would not be better done from a platform than from the shuttle," says committee member Harlan J. Smith, chairman of the astronomy department at the University of Texas, Austin. He points out that instruments mounted in the payload bay will have only about 7 days in orbit before the shuttle's fuel cells run out of power. Then they will have to come home. Compare that to leaving the telescopes on an independent space platform, where they could stay in space for 6 months or a year.

"It's an order of magnitude more exposure time for only a very slight additional cost," says Smith. Thus, more astronomers could use the instruments—astronomers never have enough telescope time—and an instrument like SOT, for example, could monitor the sun continuously for flares and other transient phenomena that it might otherwise miss. Besides, he says, a high-resolution telescope would be more stable on a

platform than on the shuttle, where astronauts would shake it slightly every time they moved.

Each payload could be placed on its own free-flying satellite, of course, just as the Space Telescope will be. But each would then have to have its own hardware for pointing, stabilization, communications, heat dissipation, and photovoltaic power. A platform would centralize those functions. William C. Snoddy, deputy director of program development at Marshall Space Flight Center, estimates that a typical scientific payload could operate for 6 months on Marshall's Space Platform at a cost of roughly $30 million—less than one-third as much as the cost on a free-flyer, and some 30 percent less than the cost on the shuttle. (The $30 million includes a portion of the cost of the platform.) Clustering the payloads would also make it easier for visiting shuttle astronauts to top off the cryogens, make repairs, or replace one set of instruments with another. They could service many payloads at once instead of chasing individual satellites all over the sky.

> The question is not whether a space station per se is worth having. A space station should be a tool, not an end in itself. The real question is whether that tool is worth the cost.

After astronomy, another prime mission for the space station is zero-gravity materials processing. There is already intense interest in both the fundamental science that can be done and in the potential commercial payoff. On the first flight of Spacelab in 1983, for example, the European Space Agency will devote 33 out of 77 experiments to materials science. NASA has an active program centered at Marshall in Huntsville. And private money is beginning to come into the field.

"We want to isolate the effects of gravity so we can better understand fundamental processes," says Lowell K. Zoller, head of the materials science program at Marshall. Six different crystallization processes are used commercially, he points out, and all of them are affected in fundamental ways by gravity. Hundreds of metal alloys have never been made on the earth because the components are immiscible and separate before the melt can cool. There are any number of ideas for making ultrapure materials that never come in contact with a container wall. "We'll need to ferry hundreds of specimens back and forth," says Zoller. "We're really looking forward to the station so we can get a lot of work done instead of one shot at a time."

The most dramatic example of the field's commercial promise is the collaborative effort of McDonnell Douglas Astronautics and the Ortho Pharmaceuticals Corporation division of Johnson & Johnson. During the past 6 years the partners have spent several tens of millions of dollars to develop the techniques of zero-gravity electrophoresis, with the ultimate goal of producing pharmaceuticals commercially in space. Candidates include insulin-secreting beta cells, interferon, epidermal growth factors, growth hormones, and as many as 40 others.

On the fourth shuttle flight a McDonnell Douglas/Ortho test unit verified that zero-gravity electrophoresis yields 400 times the output and up to 5 times the purity as the same process on the ground. The researchers are jubilant. If subsequent tests continue to go well, a production facility could be in orbit by 1987.

"We see some distinct advantages to having it on a space station," says David Richmond, electrophoresis program manager at McDonnell Douglas. Again, the main problem with the shuttle is its time limitation: "You wouldn't build a factory on Earth twelve times as big as you need just so you could run it for only one month of the year," he says. It would be much better to have a continuous process. And McDonnell Douglas finds significant improvements in cost in using the station instead of a free-flying satellite.

In a third field, communications, a space station would have little direct application because the satellites used for television, direct broadcast, business communications, and the like all occupy geosynchronous orbit, 35,900 kilometers up. The shuttle and any space station launched and serviced by the shuttle, is limited to a maximum orbital altitude of about 400 kilometers.

But a space station in low earth orbit could still prove useful in an indirect sense. Burton I. Edelson, formerly senior vice president of COMSAT and now NASA's associate administrator for space science and applications, points out that satellite communications traffic is projected to increase by a factor of about 30 between now and the end of the century. "So we will have to make optimum use of every point in the geostationary arc, and optimum use of every frequency," he says.

One solution would be to cluster very large antennas on a platform in geostationary orbit, he says. This would obviously help with overcrowding. Just as important, the large antennas would no longer have to broadcast to a whole hemisphere. Instead they could transmit spot beams, sending one message to California while—at the same frequency—sending something totally different to New York. "It would provide three times the information-carrying capacity for a given investment," says Edelson.

The problem is that the platform he envisions would have a mass of about 5000 kilograms, five times that of the largest communications satellites today. There is no way to launch such a thing directly. So the shuttle will have to bring it up in several loads, says Edelson, and astronauts will have to assemble it in space. "And then because it is precision equipment it will have to be aligned," he says. "Then it has to be mated to the booster that will take it to geosynchronous orbit." All this will require a staging area, and the logical place for that is a space station.

Back at NASA headquarters, Hodge and his task force are faced with the problem of turning these user requirements, and others, into hardware that satisfies everyone. Astronomers, for example, would clearly be happy with a Huntsville-style platform, while the construction of Edelson's antenna farm would require something very much like a SOC.

Moreover, the initial station, however modest, has to allow for growth. "We cannot envision all that we are going to do," says Hodge. One approach might be to drop the idea of a single space station, and instead imagine it evolving into a cluster of structures. At the center would be construction facilities and a manned, SOC-like module, from which astronauts would go forth to service nearby platforms specialized for such uses as astronomy or materials science.

Another problem—and, at the moment, one of NASA's most potent political problems in selling the station—is making sure that the costs can be kept under control. The station does have one key advantage, say agency officials: it is modular. "We are not in a position where we have to go to the President in a very difficult budget year and say, You

have to spend so much on a space station," says Hans Mark. "You can spend as much or as little as you want. It just depends on the time scale and the degree of urgency."

Meanwhile, Beggs has been sounding out the Europeans about cooperative financing of the station, with some success. And Major General James A. Abrahamson, head of NASA's Office of Space Flight, says that two groups have already been in contact with him about private financing of a platform for zero-gravity materials work.

Still another question is whether the station should be manned. NASA's belief in "Man in Space" often takes on a mystical quality: "I won't believe it's really a space station unless it's got a man on it," says associate deputy administrator Phillip E. Culbertson. On the other hand, as Wilfred Mellors of the European Space Agency points out, "You don't want the man to be there just to take care of the life support system." The presence of humans on a space station would add greatly to its flexibility, but also to its cost and complexity. NASA needs to do some hard thinking about when humans will really be needed in space and when machines can do just as well.

Then there is the question of the military's role on a space station. NASA, which needs all the support it can get on the project, has been courting the Pentagon actively. "It would be inappropriate to say they're highly enthusiastic," says NASA's Mark T. Nolan, a member of the space station task force. It is a very new idea, after all. "But the Air Force has formed a working group in the Space Division and interest is rapidly picking up."

Nobody is planning for the initial station to carry weapons, he adds. The details are classified, but in the near term the military missions on a station would tend to look a lot like the civilian applications: development of large antennas, for example, or satellite repair. So doing both on the same station should not be difficult.

In the longer term, however, the Air Force is very interested in such things as space-based lasers and particle beam weapons. Should they prove workable, and should the Air Force want to deploy them on a space station—and it is not at all clear that such a thing would be sensible—the compatibility problem would become severe, Nolan says. For one thing, private companies such as McDonnell Douglas and Ortho would hardly want to put their production module on a military target. For another, the Pentagon would hardly want to allow visits by foreign nationals, which would seem to preclude international participation in the station. One obvious solution, if the money were available, would be to build separate stations for military and civilian uses.

Does the United States really need a space station? In the last analysis the question is not technical, but political. As political scientist and space historian John Logsdon of George Washington University points out, "The only reason to build a space station is if there is a national decision that space is worthwhile—and that the space station is the best way to do the things you want to do."—M. MITCHELL WALDROP

Current NASA Space Station Planning

By PHILIP E. CULBERTSON
NASA Headquarters

At their confirmation hearings in June 1981, the men President Reagan nominated as administrator and deputy administrator of the National Aeronautics and Space Administration were asked what they thought the next major step in space should be. James M. Beggs, the administrator-designate, responded: a space station. Hans Mark, the deputy administrator-designate, agreed, noting that the space agency would need to work toward a permanent presence in space. Now firmly in charge of NASA, they have directed the agency to undertake planning that will lead to a space-station program for consideration by the administration and Congress as a major new initiative in space. This article reviews the steps taken to fulfill their directive, sketches actions planned for the future, and discusses a number of issues that have arisen as NASA has undertaken this task.

Reproduced from Culbertson, Philip E. Current NASA space station planning. Astronautics and aeronautics, v. 20, Sept. 1982: 36-43, 59 with permission of the copyright holder Aerospace America.

Off and on for nearly twenty years NASA has weighed the many factors involved in operating a permanently manned facility in low Earth orbit (F-1). It has examined many space-station concepts. And in 1973 the agency launched our country's first space station, Skylab, based on Apollo technology. Skylab clustered several major assemblies —workshop, airlock, docking adapter, solar observatory, and command-and-service module (F-1). Three-man crews rendezvoused and docked the Apollo command module with the station on three different occasions, with mission stay times of 28, 59, and 84 days.

Skylab demonstrated what we now take for granted: that man can function effectively in space, essentially at zero-*g*, for extended periods. It dramatically illustrated the usefulness of a crew to make repairs (to the electrical and thermal systems, compensating for damage to both during launch). It also demonstrated the value of a manned scientific laboratory in orbit. Results from eight different solar telescopes mounted on Skylab's Apollo Telescope Mount dramatically advanced our understanding of the Sun.

Two years after Skylab, the idea of a permanent station received in-depth attention: MOSC, the Manned Orbital Systems Concept. Studied under contract to NASA by McDonnell Douglas Astronautics in 1975, it emphasized science and applications for extended-duration missions. The approach taken in this study—focusing on mission requirements before configuration analysis—NASA has adopted today in order to be fully responsive to user thinking. We are now reviewing system characteristics and capabilities. MOSC geared requirements to science and applications. Today, the requirements are broader. They include national security, commercial work, and an "operations" orientation—activities of a functional nature in support of space-based operations, such as servicing automated satellites and launching propulsive stages and spacecraft to higher orbits.

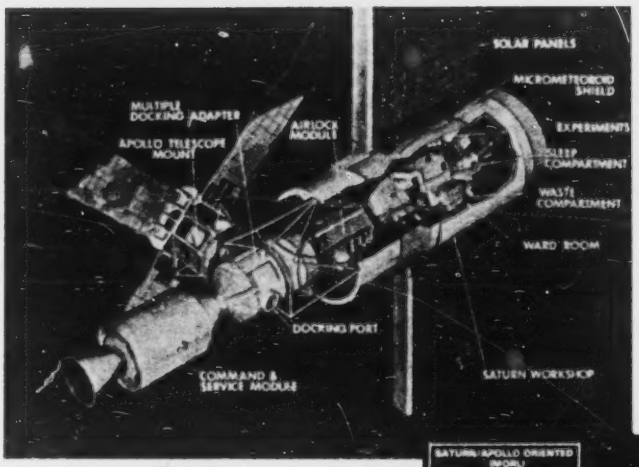
In the 1975 effort, the MOSC study team identified 46 Shuttle payloads as candidates for extended-duration missions, and grouped them into 19 payload combinations (T-1) based on equipment commonality and operational requirements. In turn, these drove MOSC design criteria, which may be summarized as follows—

—Support 720-day missions.

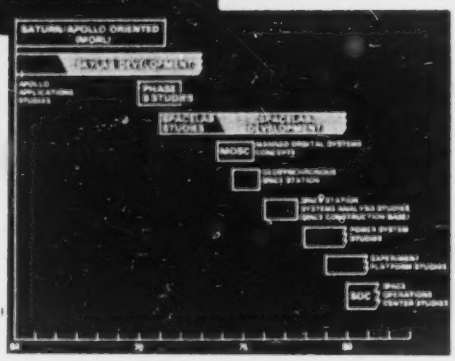
—Up to four specialists per payload combination.

—Payload power of 8 kw (supplemental to 10).

—Altitude/inclination of 230 n.mi./28.5°; 200 n.mi./90°.



F-1 Skylab explored space-station rudiments through five major sections: workshop, airlock, multiple docking adapter, solar observatory using the Apollo Telescope Mount, and command-and-service module. It was one stage in NASA's two-decades-long exploration of permanent manned facilities in space that is mapped below.



—Altitude/inclination-change capability of ±95 n.mi./28.5°.

—Orientation: all attitudes; vehicle pointing to 0.1° accuracy and fine pointing to be achieved by instrument gimbaling.

—Onboard disturbance less than $10^{-5}g$.

—Contamination control equivalent to 100,000-class clean room.

—Data management covering real-time 5-MHz transmission; recovery of hard copy, film tapes, and materials; and closed-circuit TV.

—Real-time communications to payload-control centers.

—Accommodation features: routine two-man EVA, scientific/equipment airlock, payload equipment fully accessible, and modularized payload carriers.

—Operational features: multiple simultaneously active payloads; return of all, part, or none of payload equipment; resupply of payloads and rotation of payload specialists; and double-ended universal docking provisions.

For budgetary reasons the MOSC concept was not pursued.

While we flew Skylab and explored future space-station designs, the Soviet Union systematically pursued development of a permanent manned station. Beginning in 1971, with the launch of Salyut 1, through 1982 with the launch of Salyut 7, it has conducted space-station operations and studies that apparently have yielded both civil and military benefits. Despite certain limitations, the Salyut space station represents an impressive achievement. Salyut 6 (see F-2), launched in 1977 from Tyuratam, conducted successful experiments in remote sensing, biology and medicine, astronomy, and materials processing. It was visited by eleven different crews over its five-year working lifetime. Six crews included cosmonauts from the Soviet Bloc nations. Salyut 6 was deactivated in 1981—its windows were no longer clear—but the Soviets were ready with a more capable craft, Salyut 7, which they launched late this spring.

Though the Soviet Union embarked on the Salyut space station, relying on the existing Soyuz logistics system (a reusable logistics system was to be added later), we believed the U.S. should pursue both a

space station and a new logistics system, but the review of space policy in 1971 concluded that budgetary restraints would require us to choose one or the other. We chose new logistics, a space transportation system. Now, with the development of this transportation system winding down, the time is right for planning for completion of the overall system. Our planning of a space-station program will put the administration and Congress in a position to make an informed decision on the development of such a facility, its timing, and its overall relationship to national goals and requirements in space.

With a national economy under stress, with funds for new discretionary programs severely limited, why should the nation want to commit to a space-station program? Several reasons exist, each compelling.

A U.S. space station in permanent orbit would maintain well into the 1990s our position of leadership among spacefaring nations. As evidenced by the Salyut spacecraft and by the European Space Agency's Ariane expendable launch vehicle, this position no longer can be taken for granted. In conjunction with the Space Shuttle, a station would give us the means to operate efficiently and continuously in space. Like the oceans, space would become a medium in which men and women routinely conduct useful activities. The vast potential of space would be more fully realized and the preeminence of the United States ensured.

PHILIP E. CULBERTSON became NASA associate deputy administrator in November 1981. He serves as senior staff advisor to the administrator and the deputy administrator and directs NASA's efforts to formulate policy, strategy, and planning of a facility to provide a "permanent presence" of the United States in space. From 1979 to November 1981 he served as assistant for the Space Transportation System. Earlier he was deputy associate administrator for space transportation systems (technical), assistant administrator for planning and program integration, director of advanced manned missions, and the NASA representative in the 1979 A-Sat treaty negotiations. Before coming to NASA, Culbertson was with General Dynamics/Convair. He holds B.S. and M.S. degrees in aeronautical engineering from Georgia Tech and the Univ. of Michigan, respectively.

A space station program would stimulate the development of advanced technologies across many disciplines. It would permit entry of the private sector into space by providing a microgravity facility for development and then manufacture of commercial products.

A space station could give a new dimension to the nation's space-science program. An orbiting platform would give space scientists a permanent, dependable, and versatile facility for "man-tended" facilities such as the Space Telescope and, in combination with an orbitally based propulsive stage and an orbital propellant-tank farm, a staging base for instruments and systems needing launch beyond the confines of low Earth orbit.

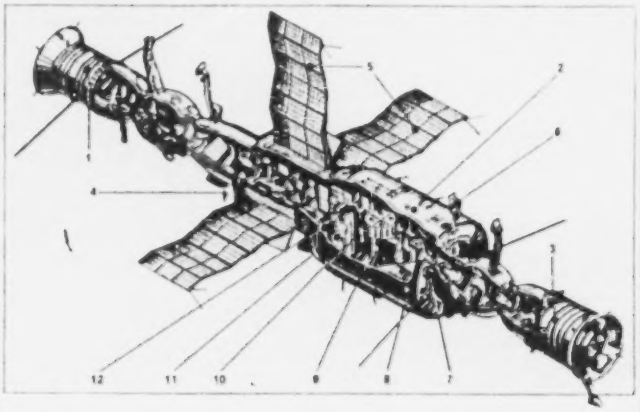
Lastly, a space station would enhance the nation's security. Readers of *Astronautics & Aeronautics* especially are aware of the role of spacecraft for a variety of national-security missions. The use of space is an essential element of our strategic posture. A space station would enhance our ability to perform these missions. At first, the station could be used to test and demonstrate new space-based systems. These systems would be developed by the various elements of our national-security establishment. Flown first aboard a general-purpose space station, they would assure the feasibility and practi-

cality of employing such systems aboard a manned orbiting space station. Later, a space station could be dedicated to national security users and employed operationally.

For the defense communities as well as the civil sectors, the space station would serve as both a laboratory and an operations base. As a laboratory, the station would provide for extended observations of the land and oceans for scientific, commercial, or defense purposes where man's presence for data integration, instrument selection and adjustment, and overall system maintenance is important. The station would enable man to participate in observations aimed in the opposite direction as well: outward to the Sun, the planets, and the stars. As an operations base, the space station could fuel and launch orbitally based propulsive stages, significantly increasing our ability to place satellites in geosynchronous orbit as well as to maneuver in low Earth orbit. The station could serve as a construction base for assembling and erecting large systems such as antennas, imaging systems, and other structures too large for launching directly from the ground. And the space station would serve as a base for maintaining and servicing free-flying unmanned satellites.

NASA's current planning focuses on the space station as a laboratory and an operations base, and on questions of requirements and architecture rather than of configuration. At this early stage of planning, the agency believes the temptation to configure a design must be resisted. Instead, we are examining constraints, systems interdependencies, growth alternatives, and limitations of flexibility.

Architecture implies a plan that defines space-station boundaries, functions, and elements. To assist in our understanding of space-station architecture, NASA is considering the concept outlined in F-3: a manned base coorbiting with several unmanned laboratories, facilities, or small platforms dedicated to specific missions, of a scientific, applications, commercial, or national-security nature. All the platforms would be delivered to orbit by the Shuttle and be Shuttle-retrievable. They would be unmanned but man-tended, either by the Shuttle or from the manned station. This station concept would consist of a docking hub, a power/utility module, and a habitat. A Teleoperator Maneuvering System based at the station would permit servicing of the platforms. In addition, manned laboratories, equipped on the ground for specific purposes, could be delivered to the station by the Shuttle. They would become a part of the station for a time, be operated by the onboard crew, and returned to Earth at the end of a mission. These labs would then be available for modification or re-equipping and reuse.



F-2 Salyut 6 orbital complex took the Soviet Union well down the road toward a permanently manned space station. Features of Salyut 6 are: 1. Soyuz spacecraft. 2. Orbital compartment. 3. Progress transport spacecraft. 4. Command console. 5. Solar panels. 6. Rendezvous antenna. 7. Correction motor. 8. Orientation motor. 9. BST-1M telescope. 10. Exercise treadmill. 11. Shower stall. 12. MKF-6M multispectral camera.

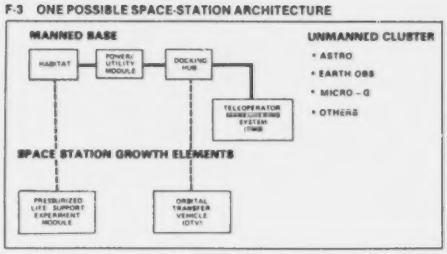
This model architecture is not definitive or fully developed. It is simply a concept employed at NASA until alternative space-station concepts are received from industry. By focusing now on architecture rather than on configuration, we hope to ensure a space station whose foundation is intellectually sound.

Nevertheless, certain characteristics of the space station are known. Whatever the final architecture, it will be Shuttle-launched and -tended. Communi-

cations will be by the Tracking and Data Relay Satellite System. At first the station may be a relatively small facility, modular in nature but expandable. F-4 shows a small facility and a later growth version. Each phase of this evolutionary system must be useful in its own right.

The space station could well be developed in concert with other nations. Under certain conditions, a cooperative space-station venture might be highly beneficial to the United States. The total system need not be manned, nor need each timed phase of the system include manned elements, but man will be an essential element of the system.

F-3 ONE POSSIBLE SPACE-STATION ARCHITECTURE



T-2 SKYLAB'S MAJOR ASSEMBLIES AND FUNCTIONS

Module	Manufacturer	Function	Habitable working volume, m^3/ft^3
Command and service	Rockwell International	Crew ascent and descent.	5.95/210
Multiple docking adapter	Martin Marietta	Docking interface, controls and display, Earth observation, and storage.	32.28/1140
Solar observatory	MSFC[a]	Solar observation, power source, and attitude control.	— —
Airlock and fixed airlock shroud	MDAC-Eastern[b]	Power control and distribution, environmental control, data center, extra-vehicular-activity hatch, and caution and warning unit.	17.66/624
Orbital workshop	MDAC-Western	Primary working and living area, laboratory, power source, and stowage.	295.23/10,426

In response to the directive to plan a space-station program, NASA has established a Space Station Task Force reporting directly to the associate deputy administrator. Consisting of some twenty individuals, in an agency-wide effort independent of but supported by the NASA program offices, it is directed by John D. Hodge, who was one of the early Houston flight directors and more recently served as associate administrator for policy plans and program management at the Department of Transportation. The Space Station Task Force has several mainstream activities:

• *Mission analysis.* The task force has underway several small studies to analyze mission requirements. They are intended to involve the user communities early in planning. Contractor tasks include obtaining the views of the users on how best a space station could fulfill their requirements and what specific station characteristics would best support their needs. The users include the science and applications communities, the commercial world, and national-security agencies. From the analysis of mission requirements, the contractors will derive space station architecture and make preliminary estimates of program costs and schedules.

• *Program-description documents.* As a means of identifying major issues and parameters of a space station program, the task force is preparing a set of documents that will set forth NASA's preliminary views on space-station planning. Patterned after the Space Shuttle "yellow books" of 1969, these documents outline and discuss the central program elements. Several documents or books on missions, system requirements, technology options, system definition, space-station initiation and operation, and station programmatics are planned. Working groups representing each of NASA's programs and centers will contribute to these documents under the overall direction of the task force. From this activity will emerge a solid understanding of a space-station program. Together with the mission-analysis studies, these documents, periodically updated, will constitute basic reference material for follow-on systems definition and development.

• *Management structure.* The task force is reviewing institutional organization and procedures for a space station program. The relative roles of the NASA centers, of Headquarters, and of the contractors need to be carefully considered. Decisions on those roles will have to be made by the NASA administrator, for they involve the future of the agency itself. No final decisions on management structure have been made. They will evolve as the planning matures.

For planning purposes the task force assumes space-station development will begin in 1984 or 1985. This date could be advanced or slipped to ac-

38-036 O - 84 - 52

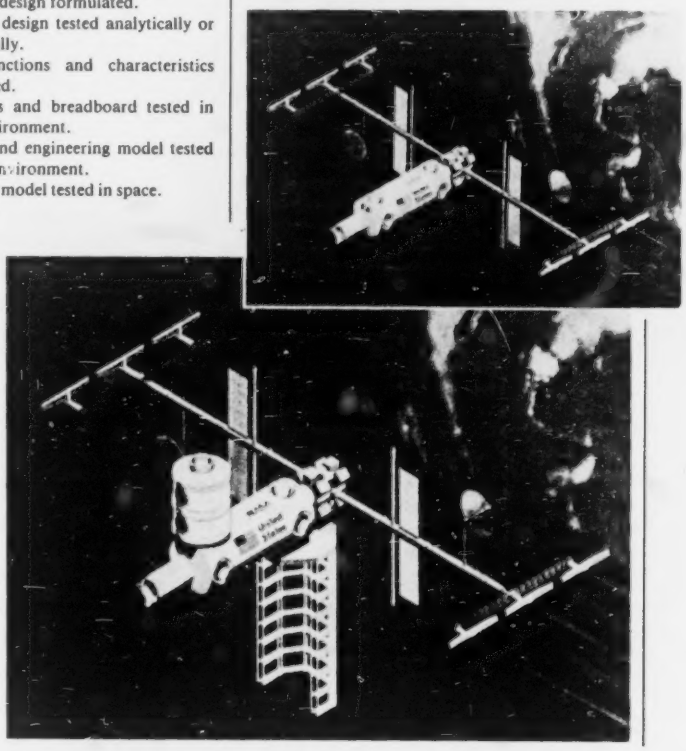
commodate the many factors and forces which influence the start of a major program. The mission-analysis studies now underway should be completed early in 1983. The program-description documents are scheduled to appear next spring. Together, this material would support space-station program definition that could begin late in 1983, assuming program approval.

In conjunction with the Space Station Task Force, NASA has established a Technology Steering Committee under the NASA Office of Aeronautics and Space Technology to assess the state of technology for a space-station program and lay out a development program that, assuming a launch by 1990, will assure technology readiness. The committee has identified the following eight levels of readiness as benchmarks for assessing space-station technologies:

Level 1 Basic principles observed and reported.
Level 2 Conceptual design formulated.
Level 3 Conceptual design tested analytically or experimentally.
Level 4 Critical functions and characteristics demonstrated.
Level 5 Components and breadboard tested in relevant environment.
Level 6 Prototype and engineering model tested in relevant environment.
Level 7 Engineering model tested in space.
Level 8 Operations.

To fulfill its mission, the Technology Steering Committee has established working groups comprised of individuals from the NASA centers and Headquarters for the following areas: data management, environmental control and life support, systems technology, attitude control and stabilization, power, thermal subsystems, propulsion, structures and mechanisms, and communications. The working groups are reviewing activities in their fields and are establishing priority tasks that would provide options for a 1984 or 1985 program start as well as options for performance improvements in a station's evolutionary growth.

As this technology effort has proceeded, the Steering Committee has realized that a number of "themes" (see T-3) cut across the various space-station technologies. They will be carefully considered in the committee's activity.



F-4 A station could begin small, as at top right, but soon evolve by adding sections, as shown below.

In addition to the work of the Space Station Task Force and the Technology Steering Committee, NASA is conducting another set of activities related to a space station. These involve the science community and are intended to ensure that science and applications requirements become an early and integral part of the planning for a space station. Through the Office of Space Science and Applications, NASA has requested a National Academy of Science (NAS) review of possible space-station utilization. Its Space Science Board spent two days this July examining how a permanent facility in low Earth orbit could serve the interests of space science. And through its Space Applications Board (SAB), the NAS later spent two weeks in August similarly examining space applications. The SAB employed ad hoc committees on Earth resources, Earth environment, ocean operations, satellite communications, and materials processing in space. The results of these two summer seminars will be used in on-going mission analyses. They also will add to the already considerable body of knowledge about the scientific potential of a space station.

The science community would be an important user of a space station. So too would the Department of Defense (DOD). Space gives to the national security communities what it gives to others: a unique vantage point from which essential activities can be conducted. A space station would carry out many such activities that otherwise might not occur. The following five national-security candidate mission areas potentially benefiting from a space station derive from a 1981 McDonnell Douglas Astronautics study entitled "Utility Analysis of a Manned Space Platform for Defense Related Missions (Task C)":

Activity	Possible program
Surveillance and reconaissance	IR telescope
Servicing and logistics	IR telescope assembly and space plane
Space command post	High-inclination mission
Data center	High-inclination mission
RDT&E	Sortie-support missions

This same study relates these mission areas to altitude and orbital inclinations (see F-5).

Given approval for a space-station program, NASA expects to develop the space station in cooperation with DOD, just as it expects to cooperate with other user communities. Such cooperation took place in the development of the Space Shuttle. The result was a vehicle of remarkable versatility and utility. We are keeping DOD advised of our space-station planning activities, and we are including defense requirements as part of the package of mission requirements to be fulfilled by a space station. For its part, DOD is participating in the mission analyses.

T-3 SPACE-STATION TECHNOLOGY "THEMES"

Themes	Components
Automation	Requirements
	Data management—
	—Architecture
	—Software and hardware
	—Data bus
	—Fault-tolerant design
	—Redundance management
	Subsystems
Human factors	Habitability—
	—Food
	—Hygiene
	—Human needs
	—Intercom
	Caution and warning
	Life Support—
	—Air
	—Water
	—Temperature and pressure
	Man-machine interaction—
	—Crew-station development
Space operations	Command and control—
	—Monitoring
	—Problem definition
	—Problem resolution
	Satellites service—
	—EVA
	—RMS
	—Teleoperation services and maintenance
	—Repair
Dynamics and control	Structural configuration and analysis design tools—
	—Dynamics
	—Thermal disturbances
	Modular growth distributed control
	Adaptive control
	Analysis and simulation—
	—Large rigid structures
	—Flexible appendages
	—Flexible structure
	Rendezvous and docking
Power and thermal-energy management	High-voltage power generation
	Power storage
	Power distribution
	Power management
	Thermal management
	Heat transport
	Heat dissipation
H_2O_2 scavenge from external tank	Cryo storage and handling
	Attitude control
	Life support
	Fuel cells
System trades	Nickel-cadmium vs. nickel-hydrogen batteries vs. fuel cells
	Closed-loop life support
	Energy storage vs. attitude control

Other participants in mission analysis are the European Space Agency (ESA) and the space agencies of Canada and Japan. They are sponsoring mission analyses of their own. Results of their studies will be shared with NASA, and NASA in turn will give them the comparable U.S. studies.

Cooperative programs with other nations are not new to NASA. Precedents for cooperation on a space-station program abound. The Space Trans-

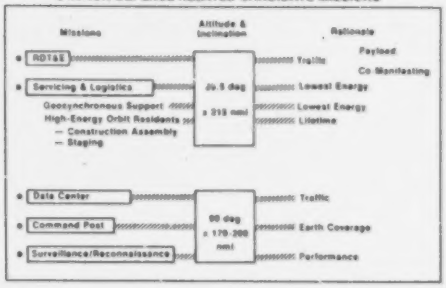
(p. 59)

NASA Space Station Planning
(Continued from page 43)

portation System (STS), for example, includes two key elements manufactured abroad. Canada developed the Remote Manipulator System; ESA, the STS Spacelab scientific module and pallets. NASA believes that, under appropriate conditions, similar arrangements could be made for a space station.

International participation in a space-station program offers benefits to the United States. International participation could lower the cost to us. It would strengthen the link between foreign space programs and the Shuttle and to U.S. space systems in general. It also would widen the technology base of the program.

F-5 ORBITAL ALTITUDE AND INCLINATION FOR SPACE-STATION DEFENSE-RELATED CANDIDATE MISSIONS



Both James Beggs and Hans Mark have spoken positively of international participation in a space-station program. At present NASA is advising potential partners of our planning activity. Results of NASA's mission-analysis studies will be shared with them. At a later date, discussions on systems development work can be expected. These discussions will, of course, be sensitive to concerns about technology transfer and to considerations regarding the exchange of funds. They will also reflect technical and managerial factors which must be considered to assure overall system-development feasibility. It appears, however, that a space station is likely to be a system of many elements, a number of which could be suitable for development outside the U.S.

Development of the entire space-station system will clearly be a challenging technical enterprise. The challenge today will not be in any one area of space technology. There will be no space-station equivalent of the Shuttle's thermal protection system or its reusable high-pressure main engines. The challenge will be to conceive and build a space station that is properly bounded, yet can grow.

Although other NASA programs have grown and evolved before, none started with evolution so significant a major objective, nor has any other evolved in the ways we envision for the space station. Obviously, one dimension of evolution would be size; the space station undoubtedly would start small and get larger over time. Another would be technological sophistication. The station must be able to accommodate new technologies as they become available. A third dimension concerns capabilities. The space station must become more useful, efficient, and versatile with time.

Unlike previous manned spacecraft, the station must have a very long lifetime –to provide a "permanent presence" of man in space. The term does not imply forever, but rather perhaps ten or twenty years. The architecture and systems design for the space station must assume and reflect such longevity. On-orbit maintenance and system upgrading will be required, something we have provided for only to a limited extent in the past.

We have confidence, however, that NASA and its industrial partners can rise to the challenges of growth and longevity, and to other challenges that will emerge as the program progresses. America's record in space is testament to this team. Apollo, Shuttle, Viking, and Voyager were all difficult programs, successfully completed. A space station provides an opportunity to continue this tradition.

The Space Age is now entering its third decade. NASA's programs of science and applications, launch vehicles, and launch services have matured. Spacecraft orbiting Earth and exploring the solar system are commonplace. Soon, access to low Earth orbit will become routine. We are thus close to being able to take full advantage of space.

What is missing, of course, is a system that provides a permanent presence. How much more useful such a presence in space would be. Our research effort in the Antarctic is not intermittent; it is a permanent presence on the polar icecap. The first explorers of our own Western frontier created the opportunity for new uses of the land, but that opportunity was not realized until settlers—farmers and miners—arrived to stay and work.

A permanent presence, whether a base camp in the Antarctic, a settler's farm in the Northwest or Oklahoma territories, or a naval fleet in the Mediterranean, establishes a new dimension: one that reflects determination, broadens opportunity, encourages participation, stimulates new activity, and strengthens the character and vision of the people who made it happen. So too with a space station. It would remain permanently in orbit, enabling us to enjoy the full benefits of space. With the Shuttle flying, it is indeed the next logical step.

Expansion into Space

Moving from Dream to Reality

by Jerry Grey

Reproduced with permission of the copyright holder from Grey, Jerry. Expansion into space: moving from dream to reality. Environment, a publication of the Helen Dwight Reid Educational Foundation, v. 25, Nov. 1983: 7-13, 33-40.

The United States space shuttle, much delayed but nevertheless one of the most significant technological achievements of the century, is now a reality. Its successful maiden flight, launched on April 12, 1981, was the first in six years to carry Americans into space. But what now? The shuttle, after all, is merely a truck, a means for carrying people and cargo into space; it is not an end in itself.

Originally the shuttle was a key building block in an overall space program plan that included orbiting space stations, near-weekly trips to the moon, and even a manned flight to Mars. That perhaps overambitious program fell to the budget-cutters' axe at the beginning of the 1970s, despite the world-shaking success of the Apollo program, which placed men on the moon and brought them safely back to Earth. The only surviving remnant of NASA's glorious space program was a stripped-down shuttle, its budget pared so close to the bone that many design and performance compromises were necessary and delays were inevitable.

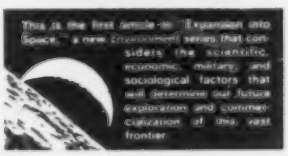
The Soviet Union, meanwhile, was quietly plodding its steady path, far less spectacularly than the Apollo program, but unerringly and unfailingly directed toward its well-defined goals. Those goals, set by the Soviet Union even before the United States formed NASA in 1958, focus on the permanent occupancy of space by Soviet cosmonauts and eventual domination of the entire cosmos by the Soviet Union.

The graceless but highly functional Salyut 6 space station, which finally plunged to Earth in July 1982 with little notice or fanfare (Salyut 7 was already in orbit by then), had been visited and occupied by dozens of cosmonauts from seven Iron Curtain nations for well over three years (1978-1981); they performed thousands of experiments aimed at learning how to utilize this vast new territory for the maximum benefit of the Soviet Union.

What will the next decade bring? Can (and should) we bridge the sizable technological and economic gap between the current generation of rudimentary space stations—Salyut, the American Skylab, and the European Spacelab—and the vast orbiting cities projected by some space visionaries? And perhaps the most important question: what would be the implications of such a move to the future of humankind?

The development of the next generation of space stations, our beachheads in space, is inevitable, not so much for the purpose of political ascendancy that motivated Apollo but for sound economic, security, scientific, and sociological reasons. The growth of these beachheads into full-scale orbiting settlements, along with solar-power satellites, the search for extraterrestrial intelligence, and eventually voyages to the stars—today hardly more than ephemeral dreams—are practical, logical and therefore also inevitable, and will totally change our perception of human existence.

In the midst of what sometimes seems to be a world falling apart around us, we stand on the brink of what could turn out to be the brightest of Earth's golden ages. This article documents not just the dreams but the reality—the knowledge and experience—on which that next great expansion is based, thereby projecting a wholly practical approach to the solution of many of today's knottiest



This is the first article in "Expansion into Space," a new Environment series that considers the scientific, economic, military, and sociological factors that will determine our future exploration and commercialization of this vast frontier.

JERRY GREY, a consulting editor for *Environment*, is the publisher of the aerospace monthly *Astronautics and Aeronautics*. He is currently vice president of the International Astronautical Federation and a consultant on space stations and international space activities to the U.S. Congress's Office of Technology Assessment. Dr. Grey was the deputy secretary for the United Nations' Second Conference on the Exploration and Peaceful Uses of Outer Space. This article is adapted, with permission, from his recent book, *Beachheads in Space: A Blueprint for the Future*, © 1983 by Macmillan, New York.

problems. One of these problems is by far the most important to us all: survival. Space is the key to its solution.

The Foundations

Long before October 4, 1957, when Sputnik 1 beeped its epoch-making way round the Earth and heralded the dawn of the Space Age, men and women were dreaming of travel beyond the Earth and planning the machines that would sustain them in the airless void.

The first concept of a true space station—a satellite orbiting the Earth with people aboard—appeared in the *Atlantic Monthly* in 1869 in a story by Edward Everett Hale called "The Brick Moon." Hale's 200-foot-diameter space station was designed to serve as a navigational aid for sailors. It included such modern features as a space-to-Earth communication system (the moon's inhabitants jumping up and down in Morse code), a resupply system (packages thrown up from Earth), an on-board life-support system (soil to grow crops that could be harvested up to 10 times a year in the cloud-free sunshine), and even such up-to-date characteristics as cost overruns.

In 1903 the famed Russian scientist Konstantin Tsiolkovsky proposed space station concepts using solar energy, artificial gravity, and closed ecological crew life-support systems. The American rocket pioneer Robert H. Goddard, in 1920, was the first to suggest that nonterrestrial materials (from the moon and asteroids) could be used to build large structures in space—a quite modern concept, considered extremely advanced even in the 1980s! Transylvanian Hermann Oberth, in 1923, built on Tsiolkovsky's and Goddard's work, predicting in his book, *Rocket into Interplanetary Space*, almost exactly what manned space platforms would be used for some 60 years later: Earth observations; bases for astronomical studies and other specific experiments; space depots for servicing, refueling, and launching other spacecraft; bases for solar space power plants; and means to evaluate human-life support systems in space. These predictions were remarkable in that Goddard had yet to fly the world's first liquid-propellant rocket (it was launched in 1926).

A Growing Interest

In 1951 Oberth's famous student, Wernher von Braun, proposed a 20-foot-diameter spinning doughnut-shaped space station. Von Braun's designs, later published in the popular press, represented the pinnacle of a quarter century of early space station conceptualization, much of which appeared between the covers of the early science-fiction "pulps." Most of the early space stations were designed to serve much the same functions as Oberth's original conception. But as experience accumulated with unmanned satellites, high-speed rocket flights, and then later with manned orbital flights, the significance of one unique aspect of spaceflight began to gain in recognition: the absence of gravity in an orbiting or free-flying satellite or space station.

There were two distinct facets to this growing interest. The first and primary one, with the idea of manned space flight in mind, was its effects on human physiology and psychology. The second, whose real importance was not recognized until considerably later in the development of spaceflight, was how this wholly new environmental feature might be used to humankind's benefit.

In considering the use of space for various purposes, one must distinguish between employing the vantage point of a platform high above the Earth—a feature used by the satellite

communications industry, weather satellites, navigation satellites, military reconnaissance satellites, astronomical and geodesic satellites, Earth resources satellites, and so on—and using the actual space *environment*; that is, the absence of gravity, the availability of an essentially infinite source of high vacuum, and the presence of undiluted, unobstructed solar energy.

The vantage-point feature was used by the very first satellites: Sputnik 1, whose beeps were heard by the entire world, making it the first "communications satellite," and Explorer 1, which discovered the van Allen radiation belts around the Earth simply because it was the first time an instrument capable of measuring them had been placed there. The space environment, however, although by now the subject of hundreds of experiments in the more recent space stations, has yet to be used for humankind's benefit.

By far the most important aspect of the space environment is what is familiarly known as zero-gravity or, more accurately *microgravity*—which means that an object in a satellite is in a condition of balance between two opposing forces: the inward gravitational pull of the Earth and the familiar outward centrifugal force due to the high speed of an object moving in a circular path. This is the same balance, of course, that keeps a hurtling satellite firmly in its orbit around the Earth.

This condition of microgravity, although its physics and mechanics have been well understood for years, presented many unknowns to those of our space pioneers, who were concerned with whether or not people could ever live and work in space or, for that matter, even survive. But as experience began to fill in the gaps in our knowledge of space flight, the shapes of spacecraft ideas underwent considerable change.

The spinning space station designs of the 1950s slowly gave way to much less complex nonspinning designs, in which crew members would experience microgravity for the full duration of their missions. The transition was accelerated by the consequences of President Kennedy's electrifying May 21, 1961, announcement setting the goal "of landing [a man] on the moon and returning him safely to Earth" by the end of the decade. Not only did it reestablish the United States' faltering prestige in the face of the Soviets' oft-demonstrated superior space capability, but it opened wide the path to ambitious planning for the next decade—the 1970s.

As the Americans and the Soviets accumulated more and more experience through the Mercury, Gemini, and Apollo programs in the United States and the Earth-orbiting Soyuz flights in the Soviet Union, the earlier bugaboos about the ability of people to live and work in space disappeared. By the time Neil Armstrong and Buzz Aldrin had fulfilled President Kennedy's promise in July 1969 by walking on the moon, with crewmate Mike Collins assisting them to guide the Appollo 11 command module to a safe splashdown in the Pacific, we had learned not only how to live and work in space for periods of up to two weeks, but also how to deal successfully with potentially disastrous emergencies, such as the explosion of an oxygen storage tank, which almost wrecked Apollo 13.

In effect, we had learned how to operate in space; now all that was needed was to find something useful to do there. That task was accomplished by both major space powers very early in the 1970s, but not before some serious soul-searching had been undertaken on both sides of the world.

Changing Moods and Missions

Late in the 1960s, as the U.S. space program was accelerating toward its sensational climax, NASA planners were busy conceptualizing their post-Apollo activities. NASA, the National Aeronautics and Space Administration, had been created by the National Aeronautics and Space Act of 1958 in response to the launching of Sputnik. Its mission, according to the law that created it, was research and the development of new space technology.

NASA's plans in pursuit of its congressionally mandated space research and development role, were ambitious: permanent space stations, starting with a 12-person design and then progressing to a 100-person behemoth; a reusable space shuttle to ferry people and cargo back and forth between the Earth's surface and the space stations; regular trips to the moon to establish and operate a permanent scientific lunar base and a lunar orbiting space station; and even a crystallization of Wernher von Braun's 1954 fantasy—a manned expedition to the planet Mars.

In the euphoria following the almost incredibly successful accomplishment of the moon landing, NASA officials proudly announced these plans to what it fully expected to be a cheering Congress and public, and promptly fell flat on their collective faces. For, despite the unquestioned success of Apollo and the unreserved national acclaim NASA received for its accomplishment, the mood of the country had changed almost imperceptibly in the last few years of the 1960s. The proposed expenditure of billions of scarce tax dollars on such esoteric and distant matters as space stations and trips to Mars for a few elite astronauts ran into a solid concrete wall, both in Congress and in an enraged American cit-

izenry. The space stations, the lunar base, and the Mars-flight dream disappeared in the political bloodbath.

But then NASA, a competent agency despite its political naiveté, came up with what later turned out to be a real winner. By early 1970, when NASA's grand plan for the future was in the process of being scuttled by public opposition, the agency cancelled its originally scheduled Apollo 20 moon flight and, instead of a full-fledged space station, announced the Skylab program, two orbiting workshops to be assembled from the leftover Apollo hardware and to be visited by seven crews over a period of two years.

Further budgetary compromises with congressional critics and the Office of Management and Budget subsequently led to an agreement to reprogram the remaining Apollo funds into a scaled-down Skylab effort consisting of only a single orbital workshop to be visited by three crews in 1973–1974. Despite the scale-down, it preserved for NASA at least a vestige of the original space station concept, which our space planners believed to be the next essential step in the conquest of space. Skylab was also needed to keep pace with the Soviets, who were even then obviously headed on a course intended to leap-frog the American moon-landing triumph by establishing a massive space station effort (see box below).

Although a makeshift substitute for even the 12-person space station NASA had originally planned, Skylab nevertheless was equipped to evaluate many of the activities that the full-fledged station had been intended to undertake. In fact, it eventually turned out to be one of the most successful and valuable space activities ever, despite the cloud of antispace feeling in which it was born.

Skylab: Shanty in Space

Skylab, the only real space station ever launched by the United States, proved unequivocally that the general-purpose computer/operator known as a human being is an in-

SOVIET ASCENDANCY

The fundamental motivation of Soviet space policy in the early years was little different than that of the United States: global prestige. The single most significant event that catapulted the Soviet Union into worldwide recognition as a major modern power and stimulated the massive American reaction was undoubtedly the launch of Sputnik 1 in 1957, backed up by the continuing string of successful unmanned and then manned space launches. From then on, it became clear that the principal strategy of the Soviet space program was to beat the Americans at every turn.

This strategy, a consequence of the basic Soviet motivation to develop global prestige as a political weapon to demonstrate the ascendancy of communism, was an outgrowth of the real Soviet military weakness at the end of World War II. At that time our big B-29s were the only aircraft capable of carrying the massive new nuclear bombs that had ended the war with Japan. Since they had no strategic air force at the end of the war, and thus no built-in airplane "constituency," the Soviets recognized the impossibility of reaching early parity with the well-established American lead.

They decided, therefore, to leapfrog the United States by developing the rocket launcher capability needed to carry their heavy nuclear bombs over intercontinental ranges. So when the International Geophysical Year rolled around in 1955, and the United States announced its intent to build (from scratch) a civil rocket and launch a scientific satellite with it, it was relatively easy for the great Russian rocket designer Sergei Korolev to convert the Soviet's existing missile launcher capability into a million-pound-thrust space launch vehicle. This big booster-rocket became the mainstay of the Soviet space program, and is still in limited use today.

According to expert Soviet-watchers, the Soviets had intended to maintain and reinforce their global image of technological superiority by beating the United States to both reaching and landing a man on the moon. They had clearly won all the preliminaries—beginning with their unmanned Luna 1, the first man-made object to reach and fly past the moon (in January 1959) and continuing through to Luna 10 (March 1966), the first spacecraft to go into orbit around the moon.

Author James Oberg (*Red Star in Orbit*) is certain that the Soviets had planned a manned launch to circle the moon in a Zond (modified Soyuz) spacecraft on December 9, 1968, two weeks before the U.S. Apollo 8 carried astronauts Borman, Lovell, and Anders around the moon. But something clearly happened at the Soviet's Tyuratam launch site, for the Soviet Union never launched its manned lunar orbiter. Never again was there even a murmur about a manned Soviet circumlunar flight. The Russians have never admitted to defeat in any arena.

Oberg has cited considerable (and convincing) evidence that the Soviets still hoped to beat the United States to the manned lunar landing. But in July 1969 the United States foiled the Soviet plan by actually fulfilling John F. Kennedy's May 1961 promise to reach the moon by the end of the decade, so again the Soviets wiped out all traces of their unsuccessful effort to win that race. From then on, they steadfastly maintained that there never had been a manned Soviet moon program.

That position might eventually have been untenable, because the whole world knew of the extensive manned Soviet activity in space, but the foreclosure of a permanent U.S. manned space station in the post-Apollo NASA massacre gave the Soviet Union the ideal opportunity: they simply said that *their* program all along had been aimed at establishing a manned presence in Earth orbit, which, besides giving them another important lead over the United States, really did have far more direct practical value than a mere prestige-building trip to the moon. And sure enough, there came another string of Soviet firsts: the first manned orbital endurance record, the world's first true space station and space-station crew, and on and on.

In the penny-pinching, post-Apollo space depression, few

dispensable element in the performance of complex, and especially emergency, tasks in space. Without the adaptability, ingenuity, and general flexibility of the human crew, there is no question that none of the Skylab mission objectives would have been achieved as a consequence of the damage the station sustained during its liftoff from Earth.

And those mission objectives were indeed important to the future of the U.S. space program, and therefore to the future economic well-being of the nation. Physiological data from Skylab astronauts established the criteria for future microgravity life-support systems, including food, exercise, recreation, personal hygiene, and physical configuration of the space craft, as well as the mechanical equipment. Skylab's medical information also defined the key physiological problems of long-term space flight—loss of calcium, muscular tissue, blood cells, etc.—which have now been solved or at least mitigated to the point at which they do not prejudice the attainment of mission objectives.

Skylab also pioneered three major lines of research in critically important areas: Earth observations, detailed studies of the Sun, and, perhaps most important, the processing of materials in a microgravity environment. Skylab taught us more about the Sun—the life-giving source of nearly all energy here on Earth—than humankind had learned in all recorded history. Those data alone were probably worth the cost of the mission; but it is as the progenitor of what will become the world's biggest 21st-century industry—manufacturing in microgravity—that will turn out to be Skylab's major contribution.

Experimenting in Space

The most important Skylab experiments were those that dealt with the growth of crystals, paving the way for major new developments in the manufacture of the semiconductor chips that are the key components in all

---

noticed that the steadily plodding Soviet tortoise had again begun to outdistance the United States hare's daring leap to the moon. The Soviets were surely and steadily designing, building, and launching new, bigger, and better spacecraft. They launched Salyut 2 in April 1973, Salyut 3 in June 1974, Salyut 4 in December 1974, Salyut 5 in June 1976, Salyut 6 in September 1977, and Salyut 7 in April 1982.

This situation highlights the fundamental difference between the American and Soviet space programs. In 1958, when NASA was created, one of the basic policies written into the National Aeronautics and Space Act was that civil and military space activities were to be conducted separately. Thus the necessary secrecy that shrouds the missions, performance, and operations of all our military spacecraft is wholly absent from NASA's civil space activities. The Soviet space program does not distinguish between civil and military operations; it is *all* secret. The Soviets pick and choose only those events and data they wish to release for propaganda, prestige, or other purposes. Besides their first seven Salyut space stations, for example, at least three additional Salyut-type spacecraft were launched that were believed by our experts to have been wholly for military purposes. Further, the "nonmilitary" Salyuts, including the intensively active Salyut 6, in which the bulk of manned Soviet activity took place, unquestionably performed many military functions.

Besides the significant military presence and substantial global prestige the Soviets garnered from their highly successful orbiting space station program, they have reaped a cornucopia of economically valuable research data. Among the valuable data the Soviets have released were the results of long stays in space on cosmonauts' physiology and psychology. The other key element in Salyut's remarkable success was the Soviets' use of unmanned "freighters" to resupply the station with rocket propellants (necessary to keep Salyut's orbit from slowly decaying, as Skylab's did, and reentering the atmosphere), air, water, food, air-filter and carbon dioxide absorption cartridges, experimental materials and equipment, and the hundred and one other necessities of a four-year, wholly self-contained combination home and laboratory. These supply rockets, named Progress, were modified Soyuz (manned) spacecraft, and the combination of Soyuz, Progress, and Salyut constitutes a complete, workable, *proven* manned space system that the Soviets have said forms the core upon which they can build their expansion into space.

There is no mistaking their intent to conduct that expansion. Although the Soviets have launched many unannounced programs that they later swept under the rug for one reason or another, they have always done whatever they've announced publicly in advance, right from the first notifications of their intent to orbit Sputnik 1 (which nobody in the world listened to or believed). In June 1980, the American publication *Aviation Week & Space Technology* reported Soviet statements that a 12-person permanent space station five times larger than Salyut would be launched in the mid-1980s, using a new rocket booster bigger than the monster Saturn V that had powered the Apollo moon flights. The big space station would be employed, among other functions, to support manned flights to the moon and eventually to Mars, according to Soviet officials.

In June 1981, the Soviets docked Kosmos 1267, a big 30,000-pound spacecraft, with the dormant Salyut 6 (42,000 pounds), with the intent, according to cosmonaut Vitali Sevastyanov, of defining modular building-block techniques for the in-orbit assembly of large manned space stations. Late in 1981 even the Pentagon confirmed the fact that Russia was developing a superbooster having "six to seven times the payload capability of the space shuttle." Perhaps even more ominous, the personnel carrier needed to go along with their new giant freighter—most likely a small version of a reusable Earth-to-orbit shuttle—was tested successfully in June 1982 for operational readiness by the middle of the decade.

Whatever happens to the U.S. space program as a consequence of budgetary and political shenanigans by the administration, there is little doubt that human beings will travel further into space within the next few years. So perhaps when Senator William Proxmire (an almost legendary foe of U.S. manned space programs) caustically queries a NASA official, "Why should we spend our hard-earned money sending people out into space? What do you expect us to find there?" he might hear the response to the same question asked 20 years ago about our going to the moon: "Russians, sir; Russians!"

J. G.

computers and modern microprocessors. Other experiments dealt with the melting, refining, and joining of metals in microgravity, currently being pursued by a number of large corporations such as Deere & Company, Bethlehem Steel, U.S. Steel, and INCO. A very important class of Skylab experiments on an obscure process called electrophoresis, although not wholly successful, did lead to the first commercially viable space products—pharmaceuticals now being separated aboard current space shuttle flights for Food and Drug Administration testing before being released for sale to the public.

Skylab was the precursor to the permanent space station concepts now being examined in depth by NASA and industry, but it was far more than that. It demonstrated once and for all that mankind can move, operate, and be productive in space, and therefore opened up the riches of the entire universe for our descendants. The major tragedy is that bean-counter-mentality budget trimming, responsible for the lack of adequate orbit-raising capability, resulted in the early loss of this nation's only space station.

Compromises and Constraints

The original Skylab mission planning had called for the lowest orbit having a sufficient safety factor to prevent reentry of the laboratory before its mission was completed; the best estimates as to its reentry and eventual fall to Earth had placed it around 1983. Although NASA was well aware of the possibility that some of the larger pieces might survive their fiery descent through the atmosphere and strike the Earth, the probability of injury or death to any person here was so small that it was not worth the money to install a descent control system on the craft.

Further, by the time Skylab was launched in 1973, the space shuttle program was well under way, and its originally scheduled launch date of 1978, even if delayed, would allow Skylab to be revisited long before its projected demise so that whatever action was then considered appropriate could be taken by the shuttle's astronauts.

The expected shuttle delay did, of course, materialize, but was somewhat longer than most people expected; the first launch was not until April 1981. That could have been in time to attach a small rocket booster unit to Skylab, either to raise its orbit and save it or to direct it into a controlled and therefore predictable reentry. But one more piece of bad luck confounded the original compromise judgment: solar sunspot activity had suddenly become greater than normal during Skylab's last years, heating the Earth's atmosphere and causing it to expand. Hence, the drag on Skylab was considerably higher than had been predicted in 1973, and it was finally concluded that the United States' only space station would tumble to its demise in the summer of 1979.

Even at this late date bad luck continued to plague poor Skylab. The inadvertent reentry of a Soviet military satellite (Kosmos 954) in January 1978, spewing radioactive pieces of its nuclear power plant over much of northern Canada, raised a global outcry about the dangers of reentering spacecraft. Skylab and its accessories, at about 175,000 pounds the biggest artificial satellite by far, was an obvious target for the world's already aroused ire. NASA came under considerable criticism for its original decision not to fit Skylab with the rocket booster system that could have prevented or delayed the reentry, a decision that had been reached reluctantly, mainly as a result of budget constraints imposed by some of these very same critics.

After all the hullabaloo, in accordance with NASA's predictions, the remaining pieces of Skylab plunged into the Indian Ocean in July 1979, and a few remnants scattered themselves harmlessly over the wastelands of western Australia. The world breathed a wholly unnecessary sigh of relief, and ignored the real tragedy that resulted from shortsighted budgeting: the United States had lost its only space station. It is hoped that the next few years will see that lost capability replaced by a new, modern U.S. space station in orbit around the Earth.

The International Team

While the Soviet Salyut and the American space shuttle were stealing all the headlines at the beginning of the 1980s, a small, slender shadow was standing quietly in the wings: the European Ariane, the first large space launcher suitable for commercial use to be developed by anyone other than the two major space powers.

By 1959 the British had developed their Blue Streak missile, which was very much like the U.S. Atlas, and in September of that year De Havillands rocket engineer, Sir Geoffrey Pardoe, suggested that the Blue Streak be used as the first stage of a launch vehicle to be developed by a consortium of European nations.

After several meetings, the European Launcher Development Organization (ELDO) finally came into being in March 1962: England, France, West Germany, Australia (*not* European, but their Woomera test site was the only available satellite launch facility), Belgium, Italy, and the Netherlands. The ELDO launcher, called "Europa," was to use the Blue Streak as its first stage, the French Coralie rocket as a second stage, and the German Astris for the third stage.

Europa established a unique history in the annals of rocketry; of all its launch attempts (except for the early flights of the Blue Streak first stage alone), not a single one was successful. The final (eleventh) flight ended in an explosion that triggered a wave of defeatism among the ELDO nations, eventually leading to the demise of the organization and aggravating still further the basic differences among the leaders—France, Germany, and England.

Ariane: The Sole Legacy

But European space activity was by

no means over. During the final death throes of ELDO, its member nations, particularly France and Germany, had proposed innumerable new launch vehicle concepts and combinations. The design that eventually surfaced was basically French, with an advanced high-performance final-stage rocket developed by Germany. It was named Ariane in 1973, and became ELDO's sole, but highly significant, legacy to Europe's space future.

ELDO failed primarily because of the political problem involved in getting a dozen nations to agree not only on what programs should be attempted but also on how much each should spend and who should design and develop the necessary hardware. The heart of the controversy was in the basic European disagreement as to whether their space program should rely on U.S. capability or be independent.

One group, principally scientists, was interested mainly in pursuing space science research and exploration, and was quite willing to satisfy its spacecraft launch requirements by purchasing existing U.S. rockets or by participating in cooperative experiments aboard American or Soviet spacecraft. Another group, however, involved with practical applications such as satellite communications and remote sensing of Earth resources, was concerned that dependence on U.S. launches might raise conflict of interest problems.

Another complicating factor could be traced directly to the vagaries of United States cooperation with Europe. In 1969 the NASA administrator, then Thomas Paine, had toured the world to explore the interests of other nations in participating with the United States in its space shuttle and space station plans. The Europeans liked the idea of involvement with the far more advanced U.S. space program, but were wary of the shaky post-Apollo political situation in the United States. They sent out cautious feelers to the United States for two different European developments to interact with the U.S. space shuttle: a space laboratory and a space tug, a rocket-propelled vehicle used to transfer a spacecraft from one space orbit to another (as distinguished from a launcher, whose purpose is to launch spacecraft from the Earth's surface into orbit).

In July 1973 an agreement was finally worked out. By this time the U.S. political situation had stabilized, but budgetary commitment to the space shuttle was so spartan that the United States had been forced to eliminate, one by one, all the options for foreign cooperation originally offered by Tom Paine in 1969 except for the space laboratory and one of the shuttle's subsystems: the big re-

(continued on page 33)

Expansion into Space
(continued from page 13)

mote manipulator arm used to move spacecraft in and out of the shuttle's cavernous payload bay.

Finally, in 1975, with the coalescence of disparate interests brought about by the 1973 agreement, the Europeans were able to put all the pieces together and form the European Space Agency (ESA), and for the first time were able to forge a strong and coherent space program for its 11-nation constituency. Under the skillful leadership of its first director-general, multilingual Englishman Roy Gibson, ESA grew into a sound, solidly structured, capable agency.

All three major programs undertaken in the agreement of 1973 were completed successfully, in contrast to ELDO's unenviable earlier record. Although Ariane's first operational flight (in September 1982) did not succeed due to a pump failure, the system has more than fulfilled its proponents' wildest dreams by attracting commercial launch customers away from U.S. launch vehicles, not only international ones like Intelsat but even U.S. corporations such as General Telephone and Electric, Southern Pacific Communications, and Western Union. And the shuttle-compatible space laboratory, now respectfully known by the proper name Spacelab, is a fully developed essential component of the over-all space shuttle program.

Just What the Name Implies

While the Europeans consider Ariane the diadem in their space program crown, it is Spacelab that will undoubtedly have the most important consequences for both Europe's and the world's future. It is the first laboratory designed wholly and specifically for research in microgravity and orbital observations, with no need to compromise those basic functions because of transportation or crew life-support requirements as both Skylab and Salyut had to do. Spacelab is therefore uniquely suited to the task it was conceived for: exploring the potential microgravity and the orbital vantage point to the maximum extent possible with the technology of the 1980s.

Basically, Spacelab is just what its name implies: a laboratory for conducting experiments in space. It is the only *manned* space laboratory in the free world, although many unmanned test facilities and crew-tended experiments have been designed and built for use in the shuttle. ESA rents Spacelab's facilities to any user, whether government or commercial, at a rate that depends on the kinds of services and equipment required. The United States, incidentally, as part of the original joint agreement, has purchased the entire Number 2 Spacelab for its own use.

The key factor in Spacelab's operation is its relationship with the shuttle. It is carried into low Earth orbit in the shuttle's payload bay, and remains there for the duration of its mission. All essential services to Spacelab and its crew are provided by the shuttle: electric power, thermal control, food, air, water, sleeping quarters, data handling, communications, and all other "housekeeping" functions. The crew moves between Spacelab and the shuttle middeck via a tunnel. Both Spacelab and the shuttle's crew compartment are pressurized to a shirtsleeve environment.

But alone, Spacelab loses many of its primary capabilities. Thus, any future for European manned space activity probably depends directly on its relations with the United States and on the health of the U.S space shuttle program and its descendants.

Further Cuts and Instabilities

Unfortunately, however, a resurgence of the American space program

instability comparable to that of the post-Apollo period began to surface late in President Carter's administration and grew to serious proportions during Reagan's term. This situation created consternation among ESA's executives, who saw bits and pieces of their cooperative programs with the United States dissolving as the U.S. space budget cuts broadened and deepened around the beginning of the 1980s.

In the Reagan-Stockman budgetary massacre that sought desperately to reduce federal budget deficits, not only was Spacelab support cut further but the Europeans' worst fears were realized: the United States withdrew altogether from the International Solar Polar Mission (ISPM), next to Spacelab the largest American-European cooperative program in space.

The ISPM was originally to have consisted of two spacecraft, one American and one European, launched toward Jupiter by a single U.S space shuttle in 1983. Each would use Jupiter's gravity to swing itself way out of the ecliptic plane (in which all the planets of the solar system revolve around the sun) and head back to the sun, where they would explore both poles of the sun simultaneously. Each spacecraft was to carry different but complementary instruments; the combination would constitute a complete, integrated experiment whose results were expected to increase significantly our knowledge and understanding of the sun.

ISPM's first hurdle, after approval by both NASA and ESA and their respective legislative bodies, was a two-year delay caused by U.S. space program budget constraints; ESA was forced to swallow a consequent $20 million cost increase. In 1980 the United States further complicated the issue by changing the upper-stage rocket vehicle that was to carry the two spacecrafts to Jupiter, and budgetary pressure almost deleted the whole program from the U.S. budget. In February 1981 the axe finally fell: NASA advised ESA, without prior consultation, that the U.S. spacecraft would be deleted from the program.

ESA was understandably enraged. Seventeen European institutes found their experiments abruptly cancelled; $100 million, half the total mission cost, in all-too-scarce European research funds had already been spent; and the United States had, in effect, reneged on a contract commitment. The United States' unilateral ISPM cancellation and cut-backs in shuttle/Spacelab integration were clear evidence to the Europeans that their early insistence on space independence was justified, and that their decisions to move ahead with their Ariane launcher and their own satellite programs, expensive as they were, had been well founded.

Manned space activities in the 1980s, therefore, undoubtedly would have been dominated totally by the Soviets if not for the Europeans. Although the European space program is still closely tied to that of the United States, for budgetary and political reasons as well as those long-term commitments that still exist, their Spacelab, used with the shuttle, is the only game in the free world's town, at least as far as civil-oriented manned space experiments go.

Orbital War Games

But the civil space program, important as it is, forms only part of the total space picture. By 1982, the Reagan administration's strong defense orientation, as well as the real long-term needs of the Department of Defense, had finally aroused public recognition of the growing role of the military in space planning. The Soviets, right from the beginning of their space program, have devoted the bulk of their attention to military considerations; it wasn't until 1981, however, that U.S. military space spending equaled (and subsequently exceeded) NASA's civil space budgets.

It is unfortunate but nevertheless a fact of life on Earth today that much of our expansion into space, and the beachheads that make that expansion possible, will be motivated not by the drive for humankind to develop and to grow but rather by our need to protect ourselves against one another. Military security dominates space development on both sides of the world. The next series of Soviet beachheads, like their last, will serve primarily military functions. There's at least a good chance that America's will, too.

Lofty Intentions and Treaties

In the United States, the National Aeronautics and Space Act of 1958, which created NASA, was careful to separate the military from the civil aspects of space activities, and also specified international cooperation, an eminently nonmilitary function, as one of NASA's primary directives. In the Soviet Union, no distinction is made between military and civil space activities, but there has always been far more than just a token effort in the nonmilitary arena, including extensive cooperation with the United States and other nations in scientific space projects.

The real drive toward minimizing the military aspects of space, however, came from the international political and scientific organizations. There were strong reasons for seeking a peaceful motivation in such matters as a global communications network, the rescue of astronauts or cosmonauts in the event of a mishap, or satellites that flew heedlessly, due to the exigencies of orbital mechanics, over national boundaries, indiscriminately photographing what lay open beneath them.

The United Nations' instrumentality set up to deal with space was designated the Committee on the Peaceful Uses of Outer Space. The principal accomplishment of that committee was the drafting and signing (by more than 100 nations, including the Soviet Union) of a Treaty on the Principles Governing the Activities of States in the Exploration and Use of Outer Space, popularly known as the Outer Space Treaty of 1967.

But despite these lofty intentions, the high ground of space has been simply too irresistible to military strategists. This steady growth in the

use of space for military purposes on both sides of the world has been justifiably noted with alarm by many nations, especially by the Third World countries, who do not want to get caught in an East-West conflict waged from above. At the same time, however, it is important that even the most vociferous critics of this development acknowledge both the reality and the complexity of the matter: specifically, that militarization of space *does* exist and that it can mean *many* things, some good, some bad.

Military satellites have orbited the Earth almost from the beginning of the Space Age. All present military satellites are passive—they observe, record, and transmit electronic messages, but they do not attack, destroy, or damage anything. Aside from the classic military functions of reconnaissance, surveillance, communications, navigation, weather prediction, target acquisition and tracking, and, to a limited degree, control of other vehicles, the present complement of military surveillance satellites is instrumental in monitoring treaties and arms limitations agreements of the adversarial nations. Without that capability there can be no verification of compliance, and therefore no effective arms control agreements.

Hence, indiscriminate, across-the-board opposition to militarization of space is not only impractical but also fails to recognize that, although militarily motivated systems may not have been conceived and deployed for the most humanitarian of reasons, they certainly contribute substantially to global peace and prosperity. Nevertheless, there still remain the specters of sudden, unseen death raining down from the blackness of space and of Star Wars-like lasers zapping peaceful satellites and vulnerable manned space stations. The major space powers, despite the obvious intent of the 1967 Outer Space Treaty, are moving inexorably toward the development of a capability for warfare in space.

New Missions, New Weapons

Early steps in that direction were taken by both the United States and the Soviet Union. In the 1960s the U.S. Air Force had proposed a number of manned spacecraft dedicated to military use: a manned orbital laboratory (which later formed much of the basis for Skylab); a rocket-launched Dyna-Soar spaceplane, whose technology was crucial for space shuttle development; a full-fledged Aerospaceplane, which was to take off and land like an airplane but was capable of orbital flight in space; and several others. The Soviets had spent considerable effort developing a Fractional-Orbit Ballistic System, which was, in effect, an orbiting bomb.

But these early space weapons were not oriented toward battle with other spacecraft à la Star Wars; they were intended to perform much the same function as the intercontinental ballistic missile or the manned bomber aircraft: the destruction of ground targets. As the ICBM and particularly the SLBM—the Submarine-Launched Ballistic Missile—became more and more sophisticated and effective, these programs to develop space-based alternatives that performed the same kind of mission became less and less attractive and, one by one, were terminated or cancelled.

But in the late 1970s developments were begun by both the United States and the Soviet Union on a new generation of space weapons oriented toward a wholly different class of missions: the destruction in space of "unfriendly" spacecraft or missiles. By moving the arena of conflict from the ground into space, these new weapons reopened the subject that had supposedly been closed by the

1967 Outer Space Treaty: the use of weapons in outer space.

The treaty specifically states (Article IV) that "the establishment of military bases, installations and fortifications, *the testing of any types of weapons* and *the conduct of military maneuvers* on celestial bodies shall be forbidden" (emphasis added). The space lawyers argue whether that clause is intended to include space, as well as the celestial bodies, since the full title of the treaty is Treaty on Principles Governing the Activities of States in the Exploration and Use of *Outer Space*, Including the Moon and other Celestial Bodies (emphasis added).

The same Article IV also stipulates that "states parties to the Treaty undertake not to place in orbit around the Earth any objects carrying nuclear weapons or any other kinds of weapons of mass destruction, install such weapons on celestial bodies, *or station such weapons in outer space in any other manner*" (emphasis added). The lawyers also argue about the definition of mass destruction. Hence there does remain a question—a space law loophole—as to whether the use of a *non*-nuclear weapon in the depths of space is forbidden by the treaty.

The "Sanctuary" Dilemma

But whether or not such a loophole does exist, both the United States and the Soviet Union have undertaken the development of antisatellite weapons, much to the chagrin of those who are concerned that space, as the most international arena, be reserved only for peaceful purposes. The growing importance of passive military spacecraft to the overall defense forces of the major powers means that they are prime military targets. Since the first job for any responsible field commander in the event of an outbreak in hostilities is to destroy the enemy's observation, command, and communication posts, which today means satellites, antisatellite weapons can be viewed simply as an extension of the bow and arrow, the catapult, the naval gun, the bomber airplane, and the air-to-air missile, all accepted as "standard" weapons.

Although antisatellites are generally considered bad by most people, there are arguments that antisatellites are neither categorically good nor categorically bad. Dr. Eberhardt Rechtin, president of the Aerospace Corporation, has said that it depends on the uses of the device. "For example," he notes,

> *if one's objective is to protect lines of communication between the United States and NATO Europe, and if Soviet satellites are being used to target weapons onto our ships, then one would view shooting down Soviet satellites with antisatellite weapons much as one would view shooting down Soviet reconnaissance aircraft with missiles.*

And he further argues against the overall "space sanctuary" concept—that all space should be off limits to military action—by claiming that

> *putting such satellites into sanctuary would seem as strange as putting Soviet reconnaissance aircraft into a prohibited target status . . . particularly when we note that the U.S. antisatellite weapon is essentially an air-to-air missile where the target happens to be at somewhat higher altitude.*

On the other hand, space is a unique region in that it is both by law and by its very nature unadorned with national boundaries. It is clearly desirable, therefore, to maintain it as some sort of nonmilitary sanctuary, as was the intent of the 1967 treaty ratified by most of the world's nations. Resolution of this dilemma—maintaining space inviolate to weapons of any kind while simultaneously depending on space for essential support of "acceptable" military operations (including treaty

compliance)—is the major question for consideration by all nations.

Directed-Energy Weapons

At the same time that the acceptability of antisatellite development is being debated in the international arena, there are indications that a movement toward exporting to space terrestrial militarism in the worst sense is already under way: the wholesale use of directed-energy weapons. Both the United States and the Soviet Union are heavily committed to research and development leading to the deployment of weapons employing lasers, beams of high-energy charged particles (protons or electrons), and beams of high-velocity neutral atoms, all of which are far more practical in the vacuum of space than they are in the atmosphere, and any of which would have obvious military applications in space. Although it can be argued on physical grounds that such devices are not "weapons of mass destruction," which are forbidden by the 1967 Outer Space Treaty, they could nevertheless lead to the rapid escalation of our terrestrial wars into space, an eventuality that is deeply and philosophically disturbing to most of the world's peoples.

Perhaps even more significant than this philosophical concern is the very practical one that a weapon capable of nullifying a preemptive strike by intercontinental or submarine-launched ballistic missiles, as the antimissile space-based laser battle station may turn out to be, would seriously destabilize the balance of terror called "mutual assured destruction," which has, at least to date, kept the major nuclear powers from destroying the world. Thus, directed-energy space weapons could turn out to be as significant a political influence as the ICBM or even nuclear weapons themselves.

Of the three types of directed-energy weapons, lasers are by far the most likely to emerge as an operationally practical weapon system. By the mid-1960s, the Soviets were intensively investigating the prospects for laser weapons—beams of high-intensity radiation capable of cutting through inches of steel in seconds at distances measured in thousands of miles. By 1982 the United States was committing $300 million annually to high-energy laser research and development; the Soviets an estimated four times as much. U.S. representatives and senators, led by Senator Malcolm Wallop (R.-Wyo.), successfully bullied the Department of Defense into making a commitment not merely to laser research and development but to a full-fledged anti-ICBM system of 18 laser-armed satellites by mid-1990, at a cost estimated to be from tens to hundreds of billions of dollars.

If such space weaponry is eventually deployed, despite vociferous global objections, people will probably still be needed to service and guide them, just as with Earth-based weapons. This possibility brings us back to the more general questions: what beachheads will be needed in space to conduct our future orbital operations? How will they be developed from what we know and have already built today? And how soon?

Building the Beachheads

The immediate and urgent problems of the 1980s of constrained capital and high interest rates, of urban decay and soaring health and welfare costs, have made it difficult for governments to invest in the development of relatively long-term, even though beneficial, enterprises such as space technology, except perhaps for sacrosanct national security matters. For these reasons, the development of our next generation of space beachheads is proceeding cautiously, with cancellations and stretchouts and public breast-beating by both proponents and opponents of space exploration in the federal and private sectors.

But cautious as it may be, development is proceeding. In the late 1970s, it was almost wholly Soviet, European, and Japanese—while the United States was deciding on the fate of the delayed and costly space shuttle. Now that the shuttle is operational, however, the United States has moved—cautiously, to be sure, due to the Reagan administration's efforts to reduce all nonmandated and nonmilitary federal budgets—toward the next step in space: planning for the development of a truly operational orbital capability to service the growing space industry, to perform the scientific and technical research needed to sustain it, and to provide the national security functions that can be fulfilled better by people than by robot spacecraft.

The Space Platform Concept

The underpinnings of that movement were laid in the mid-1970s with conceptual designs of space stations built on Skylab experience, with robot and teleoperator system designs, with unmanned, multipurpose orbital platforms for communications and scientific experiments, with large space-based power plants capable of servicing the orbital stations, and with the space transportation concepts necessary for their logistic support. Aimed at supplementing the limited-time capability of Spacelab, which requires the services of short-term space-shuttle power supplies and other houskeeping essentials, these so-called space platforms were conceived to support orbital activities for months at a time. Designed to be serviced by the space shuttle, the space platforms would have provided utilities, stability in orbit, and access to their payloads for maintenance, repair, and replacement.

The first such platforms, called "science and applications space platforms" (SASP), were to have been located in low Earth orbit, convenient to access by the space shuttle's crew. Platforms would be fitted with sufficient propulsion capability both to maintain their orbital attitude stability and to "reboost" them upon decay of their orbits due to drag, so that the Skylab debacle need never occur again. These propulsors would be refueled by shuttle crews as necessary, along with their performance of other routine maintenance tasks.

The next step was to have been to equip these unmanned low-orbit platforms with a minimal capability for manned occupancy. One approach is to hook up to the unmanned platform a modified Spacelab, thereby converting it into what NASA called a "science and applications manned space platform" (SAMSP). It would be manned only while the shuttle is hooked up to it, but unlike Spacelab, its experiments and other equipment would continue to operate in orbit after the shuttle's departure. Following that, a support subsystem module, also derived from Spacelab, capable of supporting a crew of four for several months, might be added. In this way, SAMSP and its ilk would have been, in concept, true beachheads—small emplacements on the shores of space around which would grow the larger logistic bases and ultimately the permanent stations and settlements that will lead to the expansion of humankind into the universe. The present U.S. space station program, under which NASA hopes to place its first manned station in orbit early in the 1990s, is the successor to SASP and SAMSP.

Powering the Crafts

The key to growth in space, as on Earth, is energy. But the fossil fuels that provide the bulk of power on Earth are not suitable for use in space. Their energy content per pound is simply too low to be practical on a large scale there, since every pound of material used in space, at least for the next decade or two, must be launched from the surface of the Earth by rockets at costs, even with the new space shuttle, of about $1000 per pound. Aside from limited propulsion needs and short-term requirements, therefore, power in space must be generated either from solar radiation or from nuclear fuels.

Most spacecraft in use today derive their power from solar energy, which is available in space unobstructed by the vagaries of Earth's weather. The device used to convert solar radiation to electricity is the photovoltaic converter, commonly called the solar cell. The arrays of solar cells used on Skylab constituted the highest power photovoltaic system ever flown in space up to that time. Larger panels have been under development ever since, employing much more efficient and durable solar cells and electrical auxiliary equipment. Although military requirements for extremely low mass are currently driving the state of the art in photovoltaic technology, the more or less standard silicon-cell systems have achieved a high level of performance and reliability.

Panels built by Lockheed using silicon cells manufactured by the Applied Solar Energy Corporation are capable of generating 25 kilowatts continuously, developing a peak power nearly three times that level to allow for charging batteries and for the slow deterioration of the cells due to cosmic radiation damage. These panels were originally developed as the power source for an electric rocket, called the Solar-Electric Propulsion Stage (SEPS), needed for high-energy missions to such elusive scientific targets as Halley's comet. But when the Halley's comet mission disappeared into the maw of Reagan's budget-cutting juggernaut in 1981, the almost fully developed SEPS solar power supply was adapted to a power extension package (PEP) for the space shuttle.

Such a package would allow the orbiter to remain in space for up to a month instead of only the week permitted by its chemically powered fuel cells. But because PEP was to be carried up and down in the shuttle, it didn't leave room for the kind of payloads it was best suited to service: Spacelab, for example.

PEP therefore evolved into a slightly larger power module (PM), which could extend Spacelab's staying time in orbit to two months. The power module would be carried into orbit by one space shuttle flight (along with other payloads), and would be set up, turned on, and checked out by the shuttle crew. It would be left there, soaking up solar energy to charge its batteries, while the shuttle orbiter returned to Earth for its next load. A Spacelab module equipped for habitation would then be brought up by a shuttle, would be hooked up to the power module, and would remain for one or two months. Another shuttle would then retrieve the Spacelab, bringing it back to Earth for crew and expendables replacement and evaluation of its films and data.

But Spacelabs also turned out to be budget-limited in number, so the *unmanned* space platform concept was finally born, employing the selfsame photovoltaic array design used for SEPS, PEP, and the power module. Then, should manned servicing be required, the platform could grow into a SAMSP or one of the other human-serviced systems described previously.

But to take full advantage of the available opportunities, we still need to learn how to build large structures in space. Big antennas, large solar panels to provide multiples of the power module's 25 kilowatts, and structural "buses" for multipurpose communications satellites cannot be carried up in one piece by the space shuttle. Materials and structures needed for the big, higher-orbit commercial communications satellites require some sort of "space tug" to transport them from the low Earth orbits accessible to the space shuttle up to the much higher orbits needed for such satellites.

There are many possible approaches to satisfying that need. The most comprehensive and yet perhaps the most practical of these, which would be capable not only of supporting the construction of large systems but also of satisfying most of the scientific, logistic, and on-orbit servicing needs of both government and industry, was the Space Operations Center (SOC).

The Space Operations Center

SOC was originally conceived as a possible follow-up to the unmanned space platform and its derivative, SAMSP. But in the early 1980s NASA desperately needed a highly

38-036 O - 84 - 53

visible manned space goal to replace the space shuttle as its "big project." SOC, which would circle the Earth in a low orbit readily accessible by the shuttle, was seen by its planners at NASA primarily as supporting space construction development, some military missions, and in-orbit research and commercial operations, a principal goal being the servicing of higher-orbit satellites with the aid of a space-based tug.

Although the Space Operations Center is no longer being considered as NASA's initial space station program, for the reasons stated earlier, it was the most sophisticated, imaginative, and comprehensive concept examined, and therefore is worthy of consideration as a sample of what might eventually be developed. As originally designed, SOC consisted of two slender cylindrical service modules bolted end to end, forming the spine of the space station. Attached to one side of each service module was a larger-diameter cylindrical habitation module, housing four crew members. A safety tunnel connected the outer ends of the two habitation modules. On the other side of the service modules were a logistics (supply) module and two big rectangular space-tug hangars, suitable for assembling spacecraft and their propulsion stages for outbound trips and for refueling and servicing the station's two tugs.

A construction module, fitted with remote manipulator arms and a heavy-duty cherrypicker crane, was mounted alongside one of the habitation modules. A long boom perpendicular to the main plane of the station carried two big solar panels, the radiators for dissipating the station's waste heat into space, and antennas for communicating with the Earth and with other spacecraft. A number of airlocks and space shuttle docking ports were distributed in various places on the station.

Even before the SOC concept had been discarded, though (1981–1982), it became clear that the low-budget environment imposed by the Reagan administration would not support a full-fledged development program, with a peak-year funding requirement of $900 million (1980 dollars) in 1989, which by then would nearly double as a result of inflation. NASA therefore came up with a stretched-out program, at considerably higher overall cost but with a peak-year funding requirement leveling out at about $650 million (1980 dollars) from 1988 to 1992. It also ended up with a somewhat greater capability than the original design. Here's how it was envisioned:

First, only the two service modules would be launched, along with the solar panels, logistics module, and other necessaries. Each service module would be jury-rigged to sleep and support two crew members. (Alternative starting-points could be an automated (unmanned) platform or a minimum station having only one service module equipped for a crew of two or three.) This initial configuration could develop in one of two ways. One was to add first one four-person habitation module, then eventually a second, and then the other SOC features (hangars, construction modules, etc.).

The other path would add shorter habitation modules, each capable of sustaining only two people, ultimately reaching a total of four modules. Small modules such as these are more suitable for high-inclination (near-polar) or high-altitude (geostationary) orbits, and could therefore serve as the basic design for a second SOC. Both these options end up with a total of twelve crew members, as compared with the original SOC design's complement of eight. (Boeing had projected a need for as many as fifty people in space to service the needs of U.S. space operations by the end of the century.)

Options and Opportunities

Others besides NASA and the Department of Defense see the eventual need for a space station. Many designs have been put forward, some even larger and more elaborate than NASA's relatively sophisticated SOC; others are smaller and more constrained. In all these schemes, greater attention is given to the habitability requirements of their human occupants, including both

physiological and psychological factors, than was the case with Skylab, Salyut, and the shuttle—in which human comfort was subsidiary to functional systems and hardware. Studies have identified a whole gamut of stress-inducing factors based on the data available from Skylab flights and also on the experiences of people who have been confined on Earth for long periods in similarly isolated and stressful environments.

The Soviet crews were taught how to counteract these stress-inducing factors through biofeedback and techniques for conversation, activities, and group interactions specifically designed to reduce stress. Such methods are extremely important to the success of long-term space habitation; perhaps the motivation underlying the Soviets' careful attention to them is their well-established long-term goal of dominating orbital space. Although they terminated Salyut 6 manned operations at the end of 1980 for a period lasting well over a year, this hiatus was merely a time for retrenchment and preparation for the next major phase of manned Soviet space activity.

By April 1982 the Soviets had launched their next manned space station, Salyut 7. It is their often reiterated plan to launch the new class of 12-person stations that they had announced in mid-1980, carried into orbit by their big new booster. The military superiority that station might bring them can only be imagined, but its economic benefits have been well advertised. Whether or not the United States proceeds with its space station, no one need doubt that the Russians will proceed with theirs, and the real prospects for major industrial returns for space in the next decade will bring the Europeans and the Japanese right on their heels.

Is the United States about to relive the industrial debacles of its automobile, steel, and electronic industries, and now even its once unequaled aircraft industry? America is still desperately hanging on as one of the world leaders in space, but, with present federal policies entrenched, it won't be long before that industry too will fall behind as the others did before it.

The Next Logical Extension

The "space policies" issued by Presidents Carter (in 1978) and Reagan (in 1982) were insipid "business as usual" programs that wholly ignored the urgent need for U.S. economic survival in the now global technological arena of aeronautics and space industries. Both policies leaned heavily toward the military activities outlined earlier in this article: it is not generally known that by 1982 the U.S. military space budget had exceeded that of NASA.

The consequences of these nearsighted, lackluster federal space policies were obviously well recognized by some congressmen as well as by a number of individuals and organizations. Principal among these were representatives of the growing space constituency, not only well-established professional societies but also relatively new and publicly vociferous groups such as the L-5 Society and a whole host of space-oriented political action committees and pressure groups.

Many of these organizations formulated space policy statements intended to fill the gap left by the Reagan administration in 1981 and 1982. The centerpiece of these policies, almost uniformly, was recognition of the need for permanent U.S. orbital beachheads, significantly more capable than the Soviet Salyuts 6 and 7, as focal points to support future space activities of all kinds—communications, Earth observations (including surveillance and reconnaissance), space industry, science, exploration, building future space capability, and national security functions such as command, control, and intelligence.

It was clearly recognized by these groups that, without orbital support capability, none of the perceived benefits of space industry could be realized effectively. As will be discussed in greater detail in subsequent articles in *Environment's* series, "Expansion into Space," the advanced communications platforms that could satisfy the burgeoning needs of the developing nations without geostationary-orbit saturation, leading to the "one world" of international visionaries; fulfillment of the growing global demand for nondepletable, pollution-free energy; dispelling forever the concept that the human race need be constrained by limits to growth imposed by the planet of its birth and infancy; placing the human race in the position of equals rather than inferiors in the eventual inevitable confrontation with other extraterrestrial civilizations—all these goals depend on the availability of human and material resources in orbital space around our Earth.

Our beachheads in space, like the space shuttle, are not ends in themselves. The embryo space stations we have already launched, and the bigger and more capable ones that will follow in the coming decades, are what will make possible the continued growth of humanity. Expansion into space is the next logical extension of our past movements on land, over the seas, and into the atmosphere of our home planet. And as with all growing organisms, that expansion is inevitable.

Let's just be sure we do it right.

Targeting Space Station Technologies

The options must be ready by 1986 and longer-range candidates must mesh with the evolutionary plan for a permanent space base

The next logical major step in this nation's space program has long been considered to be a permanent, manned Earth-orbiting space station, as discussed by Philip Culbertson in the September 1982 *AIA* (page 36). Our nation cannot afford to forego this step. Not only has the Soviet Union been using a small space station regularly, the Salyut, it has announced its intent to establish a permanent manned base in near-Earth orbit. Other developed nations of Europe, Canada, and Japan have shown serious interest in undertaking joint ventures with the U.S. or unilaterally if need be.

Development of technology for the proposed U.S. space station, as with any major high-technology project, must begin well before the establishment of its system requirements. The technologist must anticipate requirements. A space station comparable to Salyuts 6 and 7 could be built with Skylab-level technology, but this would not be desirable because the U.S. model would not become operational for nearly a decade. Moreover, use of available technology would not allow much poten-

tial for growth, enable cost-effective extension of station life through on-orbit maintenance, or insure affordable operational costs. Indeed a Space Station Technology Steering Committee (SSTSC) established by NASA (see box on page 30), has concluded that *now* rather than later, we should be innovative and take risks in aiming advanced and unproven technology at the space-station design goal.

The SSTSC has set the following objectives:

- Establish the desired level of technology to be used in the initial design and operation of an evolutionary, long-life space station and the longer-term technology to improve capabilities. (Initial technology should be available by about 1986 to support a space-station launch as early as 1990.)
- Assess the level of technology forecast to be available from the current R&T base.
- Plan, recommend, and monitor a program to move the current technology to the level stated in the first bulleted paragraph above.
- Identify, evaluate, and recommend opportunities to use the space station as an R&T facility.

Development of a permanent manned space station has continuously been the subject of consideration since the beginning of the space age. In 1952 *Colliers* magazine described a space-station concept advanced by a group of space pioneers including Wernher von Braun, Joseph Kaplan, Frederick Whipple, Heinz Haber, and Willy Ley. The opening of space flight spurred numerous station studies, activities, and several experimental stations:

1952	*Colliers* magazine article "Man Will Conquer Space Soon" (von Braun, Kaplan, Whipple, Haber, Ley, et al).
1958	*London Daily Mail* "Home in Space" space-station design contest won by Douglas Aircraft.
1959	Military Test Space Station studies conducted.
1960	IAS/NASA/Rand Corp. Manned Space Stations Symposium.
1963	Langley Research Center establishes an office to study the Manned Orbiting Research Laboratory.
1964	DOD initiates Manned Orbiting Laboratory studies.
1967	Planning begins for post-Apollo space station later known as Skylab.
1971	Salyut I launched April 19.
1973-76	Salyuts 2-5 launched April 1973, June 1974, June 1976.
1973	Skylab launched May 14.
1975	Manned Orbital Systems Concepts study of Spacelab-derived configuration.
1977	Salyut 6 launched in September.
1979	Space Operations Center study undertaken.
1979	Science and Applications Space Platform study undertaken.
1982	Salyut 7 launched in April.

WALTER B. OLSTAD (M), associate administrator for management, chairs NASA's Space Station Technology Steering Committee. He came to Headquarters in 1979 from NASA-Langley where he had served as chief of the Space Systems Division.

Several trends have emerged. All of the early designs proposed rotation of all or part of the station to provide an artificial-gravity environment for the crew. Actual flight experience indicated that a well-conditioned crew can stand a zero-g environment for at least 180 days. Some risk of space sickness remains (usually restricted to the first several days of zero-g exposure) and some difficulty in reacclimation upon return to the ground. We still do not know the long-term effects of zero-g, but the regularity of Shuttle flights removes this as a practical concern in the near term for an Earth-orbital station.

Many early space-station concepts assumed nuclear power systems. Lack of sufficient technical progress caused this option to be dropped. Meanwhile, the solar-cell power system became the leading candidate, surpassing both nuclear and solar-collector heat-engine systems.

Another trend in U.S. studies has concerned extravehicular activities (EVA). Some designers concluded it should be used only for contingencies, minor construction work, and limited payload handling—despite the important role of EVA in the Skylab and Salyut programs and its dramatic extensive use in the Apollo program. A change from the 5-psi oxygen-rich atmosphere of Skylab and Apollo to the 14.7-psi atmosphere of Shuttle complicates EVA by requiring extensive periods of prebreathing or development of a higher-pressure EVA suit. The reservations of some notwithstanding, EVA will become, we believe, part of routine space-station operations to gain flexibility and lower costs.

Use of residual payload capacity for in-situ test and checkout of space station subsystems while still under development can reduce the need for elaborate and expensive ground facilities and verification programs. Later, during station operation, use of residual payload capacity for resupply also will help reduce costs. Being chiefly a logistics vehicle, the Shuttle will not remain with the space station. It cannot be counted on for immediate evacuation in the event of an emergency. Other means to assure

SPACE STATION AND SPACE STATION TECHNOLOGY STEERING COMMITTEES

To plan and coordinate a space-station program, NASA has established an agency-wide management structure independent of, but supported by, its program offices and centers. A Space Station Steering Committee chaired by Philip E. Culbertson, NASA associate deputy administrator, leads this effort. The steering committee consists of the NASA associate administrators, the director of the Space Station Task Force, and the chairman of the Space Station Technology Steering Committee (SSTSC).

The task force, under John D. Hodge, directs analysis of mission requirements, development of a set of program-description documents, and review of institutional organization and procedures for a space-station program.

The SSTSC, chaired by me, covers technologies in the spectrum from basic research to project development. Its members are listed below.

In addition to the work of the task force and the SSTSC, the steering committee coordinates science and applications requirements to assure that they become an early and integral part of the space-station planning. The National Academy of Science convened its Space Science Board and its Space Applications Board this past summer to study potential use of a space station. The results help guide inputs to contracted mission-analysis studies. The steering committee also coordinates cooperative and complementary activities with the DOD, the European Space Agency, and the space agencies of Canada and Japan.

crew safety are under study.

Advances in a number of technologies create a richer store of design possibilities than ever before. Modern electronics especially offer major improvements in autonomy, reliability, flexibility, and cost. Likewise, we have a fresh outlook on the role of people in space. Skylab demonstrated that man can play a useful role. New technology in a space station for the 1990s surely can amplify his usefulness, particularly when armed with the resources of the new electronics.

The Soviets, it should be noted, talk openly of their plans for a large, permanent manned space station targeted for 1985. It would require a booster more powerful than any previously developed by the USSR. The first test launch of this booster may come this year. The Soviets, moreover, have indicated that they are working on a shuttle vehicle to be available in 1987. A 1/20-scale model was test flown last year.

In view of these trends, among others, the SSTSC proposed a list of possible space-station requirements to give guidance to technology development. Frequently reviewed and changed, the list now reads as follows:

- A manned system in low Earth orbit.
- Shuttle-compatible for delivery, assembly, and disassembly.
- Shuttle supported, initially on 90-day cycles.
- Modular and evolutionary design to permit growth and accept new technology.
- Goal of indefinite life through on-orbit maintenance, repair, or replacement.
- Support scientific, commercial, and military uses including on-orbit satellite servicing.
- User-oriented to the extent possible.
- Life-cycle cost to be a design driver.
- Final design phase during 1987 to support first flight as early as 1991.

Items in the list still have not become very specific. For example, although calling for a crew, it does not stipulate crew size and qualifications, typi-

cal and maximum stay times, work cycles, EVA requirements, etc.

The list of requirements implies a much larger number of design options and constraints. Operation of the station in low orbit, whatever the inclination, implies propulsion for drag make-up either integral to the station or through the aid of the Shuttle; an understanding of an acceptable level of protection from radiation, space charging, and self-induced contamination; and a need to accommodate thermal cycling, communications through ground or satellite relays, and energy storage if the power-generation system depends on the Sun.

Use of the Shuttle imposes obvious limitations on module size and schemes for deployment, erection, and assembly. On the other hand, it should permit economical resupply of the space station as an adjunct to its regular missions.

Two of the more challenging requirements concern modular and evolutionary design and achievement of indefinite life. They imply both an opportunity and a need for repeated infusions of new technology into the system. But how can this be done while keeping life-cycle cost within reasonable bounds? How much and what new technology should be included at the beginning? How much and what should be phased in later? How insure that the initial modules will readily accept new technology at a later time? How can maintenance, repairs, and modifications be performed without interrupting critical functions?

The answers proferred often involve the terms "transparency to technological change," "robustness," and "provision of functional interfaces." Unfortunately, such answers carry little useful knowledge, just new jargon.

Designers should take heart, however. Computer-aided design is proving to be a revolution, not simply because it is doing away with the drawing board and the gum eraser, but because it is eliminating a large fraction of the costly errors that occur during fabrication, by performing fit and form checks on the computer instead of with prototype or engineering models of the product itself. Extension of this kind of computer-aided modeling to the problems of repairability, maintainability, operability, and subsystem interfaces could greatly facilitate evolutionary change. Application of decentralized design wherein nearly autonomous subelements are linked through a common high capacity bus to a high level controller might allow service-oriented systems (power distribution, thermal management, communications, and stability and control) to adapt effectively to change. New ideas about design organization, associated with applying artificial intelligence, may likewise help formulate efficient evolution of a station.

Scientific, commercial and military uses generate a number of difficult and often conflicting design challenges. Scientists will insist upon a lean, quiet, disturbance-free environment, very precise pointing, and a high level of stability. Many experiments they will want isolated for long periods, and others given frequent attention as targets of opportunity present themselves or consumables approach depletion. A great deal of data will be generated. Should it be transmitted directly to the ground in real time or at more convenient opportunities? Should it be processed on the station? Should control of the experiments be from the ground, from the station, or automatic? Should scientific equipment external to the station be serviced by means of EVA, with teleoperators, or brought into a shirtsleeve-environment workshop? Commercial users may wish to restrict access to work of proprietary interest. They may have awkward power, heat-rejection, and resupply requirements. The military will, of course, demand security and priority. Satellite servicing will require that the station have the ability to fetch, dock, and restrain the satellite and then to provide the appropriate service such as refueling, repairing or replacing components, recharging or replacing energy storage devices, reconfiguring subsystems, refurbishing thermal-control coatings, etc.

For the long lived space station, life-cycle cost must drive design. Too often budgetary pressures have caused project managers to trade savings in initial development cost for large operational expenses later. Such trades made for the space station could price operations out of reach. Certainly the ability of the station to achieve at some time in its evolution a high level of autonomy will greatly reduce operational costs. Technological considerations should be brought to bear *now*, before it becomes too late. Currently, during on-orbit operation the Shuttle requires *hundreds* of ground controllers and mission specialists to monitor and supervise functions at a very detailed level around the clock. Each mission requires the generation of *volumes* of minute instructions, plans, and alternate plans followed by extensive simulations. Payload preparation is exceedingly thorough, tedious, and time-consuming. In short, space flight, especially manned space flight, continues to be very labor intensive. The technology to reduce the labor required is close at hand, but it must be focused on specific space-station requirements. That must be done *now*—and without simply trading ground controllers for software-maintenance specialists.

Closing of life-support water, air, and even food

cycles may also be economical in the long run because of cumulative resupply costs. The option to achieve those goals should not be ruled out by failure to address technology required now.

Constant access to solar energy causes some to dismiss energy efficiency as an important consideration. When life-cycle cost is considered, however, energy efficiency may well be a goal worth seeking. The most efficient power generation and distribution system will require the smallest possible solar arrays and thermal radiators. In turn, smallness will allow a low-drag configuration and minimum need for propellant for drag make-up. Small arrays and radiators will also simplify attitude control and stabilization. Energy-efficient systems tend to be longer lasting, entailing less heat, wear, and fatigue.

Another means to keep space-station operational costs under control may be to use the station itself as the test bed for most future growth developments rather than to maintain a ground-based high-fidelity replica.

Most form, fit, and function checks could probably be done by computer. It is not completely obvious that such an approach has advantages, but it appears attractive enough to warrant serious study.

As mentioned, we need a better understanding of man's ability to adapt to and function in the space environment. That calls for deeper understanding of man-machine interactions.

The final requirement relates to the proposed project schedule. We have only a few years to get technology to the necessary readiness without incurring excessive technical risk or residual development cost. We must array the technology options and set priorities to use available resources effectively. And we must coordinate the relevant programs of NASA, DOD, and industry to assure the most productive overall program. (The total industry IR&D effort already comes to several times that of the NASA-funded program.) In this respect, care must be taken to assess technologies that will phase in at later times.

A year ago, the SSTSC established nine groups to work out these needs, and added a tenth dealing with human capabilities last summer. Each working group has eight to ten technical experts selected from the NASA field centers conducting relevant activities and from the sponsoring Headquarters program office. Over the past year they have been assessing on-going R&T program plans, and recommending efforts for the FY84 NASA budget submittal. The chairmen of these working groups have written the articles which follow dealing with the technology challenges and opportunities. In their overviews you see the shaping of a new space era.

SPACE STATION TECHNOLOGY

DATA SYSTEMS

Optical Bus Will Connect Distributed System

By WILLIAM L. SWINGLE
NASA Johnson Space Center

As a general point, the engineers in aerospace know well the avalanche of emerging technology and technology products in information and digital-data systems. The space station will profit from this bounty, including recent advances in the generic technologies of automation, artificial intelligence, and so-called "expert systems."

While the space station proper will be an orbiting entity, in terms of data systems it forms but one element in a potentially large and complex network of distributed elements in a space operations system. F-1 gives a general idea of the potential scope of the distribution network. Besides the space station itself, the orbiting elements will include the Space Shuttle, communication relay and navigation satellites, orbital-transfer vehicles, extravehicular crew members, and tended free-flyers. Ground elements will include control centers, receiving stations, data archives, and a host of users, all demanding in some form or another data and some control access.

Ideally each user will have access to his domain of interest through a data system service that is stable, functionally transparent, and easily understood ("friendly") at interfaces. The local networks will be interoperable with cross-system access to distributed data bases in some reasonably automated fashion. Optimal use of automation will enable cost-effective performance of critical real-time functions, housekeeping tasks, mission planning, procedures development, and background analysis and service funtions.

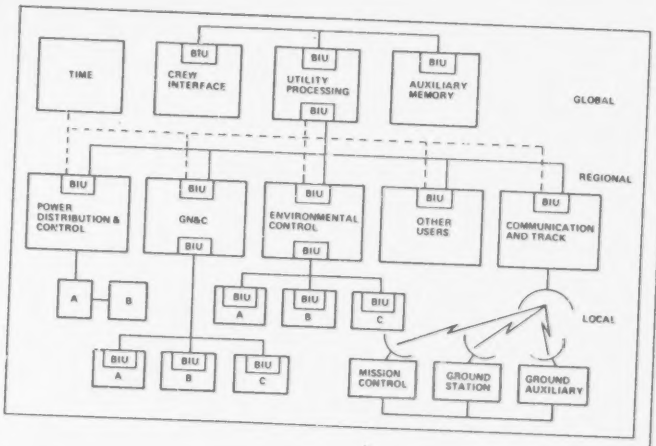
WILLIAM L. SWINGLE, as assistant chief of the Avionics Systems Div. at NASA-Johnson, manages division support of space station technology and advanced development. He played a large part in developing Apollo and Shuttle avionics.

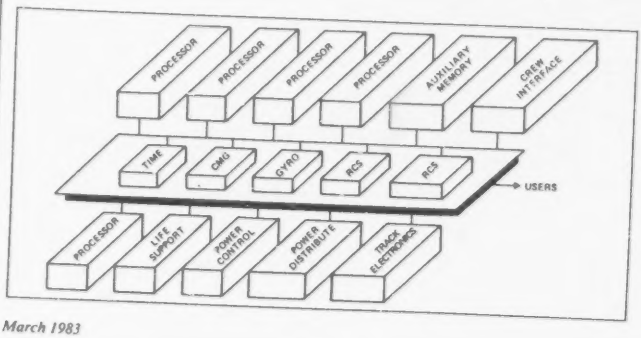
F-1 **Not the space station alone,** but rather a complex distributed network will characterize data systems.

The designer faces many problems in treating such an integrated system:

- All of the distributed network elements are in themselves complex regional-level networks with demanding requirements.
- The space station proper will probably involve at least three development phases: core-system and habitability modules, and operations facilities.
- The station and attached modules will be developed somewhat separately over its long life.
- The evolutionary pace of many of the existing local systems will be prejudiced by considerations of investment and immediate needs.
- The ground-user community will grow and change over the operational lifetime.
- All system elements will suffer pressures for

F-2 **HIERARCHICAL FORM OF ONBOARD DATA SYSTEM**





F-3 **GLOBAL FORM**

technology updates to improve productivity and combat obsolescence.

The onboard data system and other new elements to the network as they are developed should strive toward compatibility with idealized goals. The data system interfaces, services, procedures, and protocols need to be standardized and remain stable so that other parts of the system can be easily changed and upgraded later. In place portions of the ground systems should move toward these goals in some organized evolutionary manner.

There will be intense and continuing technology developments driven by needs and opportunities unrelated to space stations in commercial, scientific, and military areas. Continuing effort will be required to tap and adapt this evolving technology to the needs of space systems.

A technically adequate system might be designed using yesterday's technology along with off-the-shelf systems or system elements. This approach is not usually perceived as the most frugal, but it has a short handle.

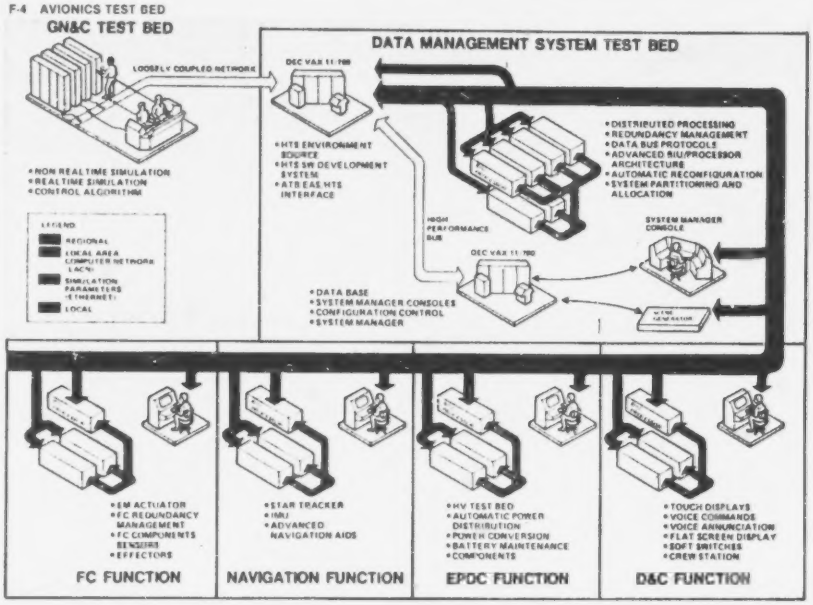
Selection of the most recent technology base will tend to optimize utility and operational program costs, but overly optimistic assessments of readiness will penalize development costs and manageability.

In general, extensive functional distribution, carrying out relatively independent smaller projects, can lower software and verification costs and aid manageability. It usually costs more, however, in terms of hardware and software resources. That calls for adroit use of standardization and commonality. There will be numerous opportunities to capitalize on the economies of commonality in terms of hardware, software, software tools and facilities, and verification. Inadequate memory and time margins can have an explosive effect on software and verification costs.

Fault tolerance is one of the more difficult technical areas to attack for all systems. The development of effective specifications involve reliability, function criticality, onboard maintenance, the environment, tolerance for operations downtime, Shuttle-revisit cycle time, and rescue.

"Verification" of both software and hardware/software systems will be major cost-drivers.

F-4 AVIONICS TEST BED



The evolutionary nature of the system along with the extensive volume of expected software are largely responsible for the scope of this problem, and running equipment up and down with the Shuttle will prove a costly way to solve it.

One concept of the onboard data system illustrates some of the technology challenges and activities.

The general topology is distributive. At least two approaches have been considered, and there are many more. F-2 shows a hierarchical concept. In it the interfaces between subsystems must be loosely coupled—no time-critical relationships beyond broad bus limits. One of the nodes will have a dedicated interface to a ground station under control of the onboard system. There is a separate timing bus as a common reference. Standard devices called bus interface units (BIUs) are assigned to subsystems. It is expected that the BIUs will handle the equivalent of least the first six network layers, as defined by the International Standards Organization. This will be an open system, with adaptive or autonomous nodes, so that expansions will be fairly transparent to users. Subsystem elements will probably employ embedded microprocessors for local services.

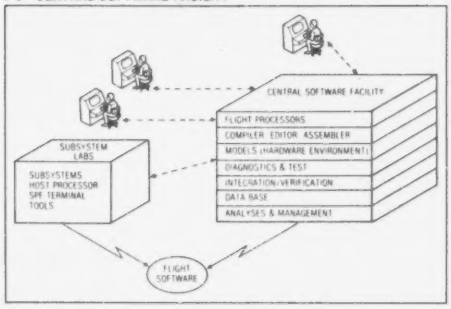
F-3 depicts a global approach with all processors interconnected to all sensors and controllers. The processor array can be viewed as a centralized multiprocessor. This scheme allows more flexibility and more efficient use of resources. However, functional separation is less explicit.

Application of wide-scale, open-system distributed architecture will be new to manned space vehicles. It will call for a major design effort. Eventual designs need to be supported by early proof-of-concept testing in representative arrangements. F-4 illustrates a concept for doing this employing most of the system concepts and technologies of interest. It includes the transport of software developed in an offline simulation into the test system.

The fiber optics buses will have data rates of at least 20 Mb/sec. Space qualification of candidate fibers and optical-bus components by NASA-Goddard is in progress.

The eventual network-interconnect scheme is uncertain. NASA has work in progress on star, graph, and ring type systems using electrical and fiber-optic media. A NASA-Langley effort on graph networks includes adaptive-fault-tolerant and self-correcting operations. A breadboard program at NASA-Johnson includes evaluation of the previously discussed BIU approach in an adaptive and fault-correcting chordal or concentric ring type network. Fiber-optics would allow an evolution to wave-length modulation. NASA-Langley is doing work on these components and systems.

F-5 CENTRAL SOFTWARE FACILITY



Auxiliary memory will probably use magnetic-bubble technology. Current NASA efforts concentrate on improving storage density and performing system level proof-of-concept testing. Access time, memory density, and reliability will be substantially improved over tape systems. Optical-disk (laser) systems will be assessed as a higher performance option.

No clear preferred strategy on processors for the space station has surfaced. Technology efforts involving alternate approaches to fault-tolerant processors are in the demonstration phase at Langley. The Jet Propulsion Laboratory has been doing advanced work on fault-tolerant computer modules.

Commercial and military development in microprocessors appear very suitable for space-station support; e.g., the Intel 432, Air Force Mil-Std 1750/9450, and Conklin chip-set developments. The 432 architecture looks highly desirable for multi-tasking and fault tolerance, particularly as coupled with Ada-supported software. Compatibility with space environments is an unresolved issue.

And, finally, software—a bugaboo on everyone's mind in terms of cost, program control, and reliability—raises concerns about adaptation of existing tools, standardization and commonality, management, "verification," criticality classification, interface stability, transportability, and automation (could create huge demand on software sizing). It will be a large order to come up with the right answers. The DOD software initiative that is built around the Ada programming language will provide one focus.

The concept sketched in F-5 would greatly aid software development and production. It would be accessible to subsystem users through remote terminals and a higher-order-language interface. Laboratories would use additonal colocated equipment as would be necessary.

SPACE STATION TECHNOLOGY

ELECTRIC POWER

Looking at Regenerative Systems

By J.L. MILLER
NASA Marshall Space Flight Center

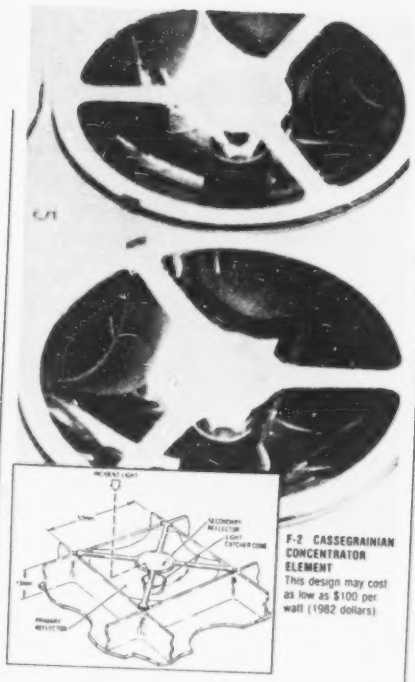
The Skylab mission taught the importance of abundant electrical energy for manned space operations. When it lost 25% of its power-generating capacity, the crew had to spend much valuable time juggling their activities to keep power demands within the capacity of the system. The cost of managing a large space system with marginal power is only half the problem. With ever-inflating costs of power hardware, the prospect of providing excess capacity decreases with each successive project.

For alleviation for a space station, two objectives have been incorporated into the electrical-power-system technology program: lowering of life-cycle cost and provision for autonomous management.

To understand the cost and management problems associated with space power systems, we must examine the system elements and consider operations associated with each: generation, storage, distribution, and control. A well-designed system will give the same type of electrical service as a commercial utility. A user should be able to turn his load on and off and expect it to receive electrical power and function normally with no other load being affected and with full assurance that the required energy will be available. An overload or other fault should cause only a minimum "blackout." Critical-load buses will be supplied through redundancy, providing maximum assurance of adequate power.

Also, analogous to the terrestrial electrical utility, the space power system needs a multiplicity of sources, storage elements, and distribution paths —so-called "vertical segmentation" (achieved by allocatng portions of the power-generation equipment to portions of the energy-storage hardware and feeding power through switch gear to multiple distribution buses). Prudent design dictates the cross-strapping of power-system elements to minimize the effects of hardware failures.

J.L. MILLER is chief of the Electrical Division, Information and Electronic Systems Lab at NASA-Marshall. He is a member of the AIAA Aerospace Power Systems Technical Committee and has a masters degree in electrical engineering.



F-2 CASSEGRAINIAN CONCENTRATOR ELEMENT
This design may cost as low as $100 per watt (1982 dollars)

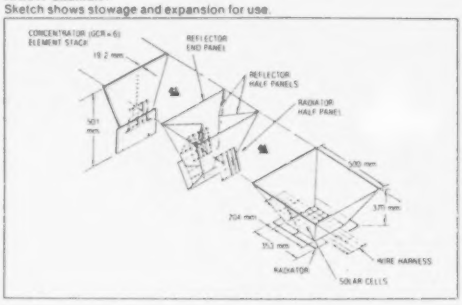
Large space-power systems capable of operating at low Earth orbit (LEO) for two to five years today have recurring cost of the order of $800 to $1,000 per watt (of orbital average power available from the system). This applies to a classical photovoltaic source with nickel-cadmium (NiCd) battery storage supplying 28-V d.c. power and with semi-automated control and management. Large numbers of silicon photovoltaic cells needed make the solar array the highest cost element of the classic source.

Chemical fuel cells and nuclear reactors with thermoelectric power conversion represent alternatives for electrical power generation. (Primary batteries are not an option due to their low specific energy, typically less than 100 Wh/lb.) The primary fuel cell is an attractive candidate since electrochemically it does not consume itself as primary batteries do but consumes resupplied reactants, such as hydrogen (H_2) and oxygen (O_2), at a rate of about 1.0 lb/kWh including purge requirements to clean out accumulated impurities. Today's cells lack the long life desired, and the system designers

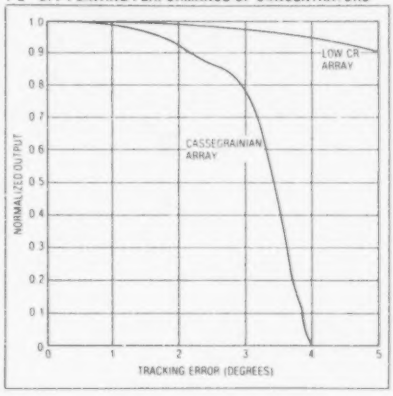
have not settled on a mechanism for resupplying fuel-cell-grade oxygen and hydrogen in orbit.

A nuclear reactor coupled with thermoelectric elements that convert heat directly to electricity offers efficiency in terms of specific power, but this type of system requires extensive development, and basic facets of it, such as operational safety and fission-product disposal, have not been sufficiently addressed. Thus the photovoltaic solar array dominates space-station planning for the late '80s. Even so, over the next few years much must be done to reduce fabrication cost and increase the life of arrays. The leading candidate for achieving these goals is the concentrator array, in which highly reflective surfaces concentrate solar energy onto the solar cells. Being less expensive than cells, concentrators with reflectances greater than around 0.85 should considerably reduce the cost per watt of generated power.

F-1 LOW-CONCENTRATION-RATIO (LCR) CONCENTRATING-ARRAY ELEMENT
Sketch shows stowage and expansion for use.



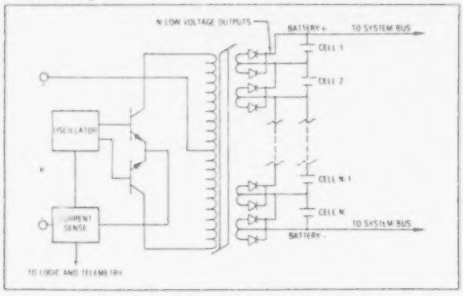
F-2 OFF-POINTING PERFORMANCE OF CONCENTRATORS



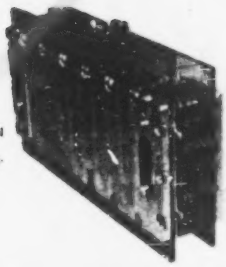
Two types of concentrator arrays are being considered. F-1 shows a concentrating array element having a low geometric concentration ratio (GCR) of 6. Considering reflector losses, it produces an actual solar flux density of about 5 Suns at the cell surface. The second type, see opening illustration, employs a cassegrainian concentrator to produce an actual flux level of about 100 Suns on the cell surface. It has a GCR of 120 before reflector and masking losses. Both types greatly reduce cost —from some $300/W for planar arrays to possibly $250/W for the F-1 design and perhaps as low as $100/W for the 100:1 design (1982 dollars).

The F-1 array can use cells similar to planar arrays, with similar techniques of cell bonding and interconnection. This array is relatively insensitive to off-pointing (F-2). It is considered a relatively low technology-risk for early space-station use.

F-3 BATTERY PROTECTION AND RECONDITIONING CIRCUIT
Simplified diagram.



The cassegrainian approach requires a new cell to be developed and new techniques of incorporating the cell into the system, in part because of the small size of cell used (only 4 mm in diam) and the fact that it operates at 100 Suns of solar flux and at a high current density (25 mA/mm²). Even at this high flux level, the cell does not require active cooling. Operating at a temperature of around 80 C and at 100 Suns of flux, the small GaAs cell under development for this array by NASA Lewis Research Center may yield an efficiency greater than 20%. Due to passive cooling, higher cell efficiencies, and good area utilization, the cassegrainian array offers a very attractive advantage over planar arrays—greater power output per unit area. A planar array can produce nominally 100 W/m². The cassegrainian approach should yield at least 125 W/m². That



F-4 BIPOLAR NICKEL-HYDROGEN FUEL STACK
Ten 0.24-sq-ft series-connected cells.

means less drag and therefore lower requirements for station-keeping propulsion.

The cassegrainian design presents a moderately high technology-risk for the initial space station. It requires a much higher degree of planarity than the F-1 design. Both require reflective surfaces that will suffer little degradation in the space environment. A comprehensive technology program managed for NASA Office of Aeronautical and Space Technology (OAST) by NASA Marshall Space Flight Center (MSFC) treats these problems, aiming for a concentrator array option for the initial station, and to verify the technology by test hardware.

High concentration ratios do not necessarily imply significant depth to the array. Cassegrainian array panel designed for operation at an effective GCR of 100 has a thickness of only 13 mm—about the same as a typical planar-array panel with a honeycomb substrate. It would have about the same packing density for launch. Moreover, cells of the cassegrainian array take only about 1% of the deployed area and, although considerably more expensive per unit area than cells for a planar array, produce energy at much less cost.

While the predominant problem in solar arrays has been cost, the big concerns in energy storage have been mass and lifetime. Historically, energy storage has been accomplished almost entirely by secondary nickel-cadmium (NiCd) batteries at a specific performance of around 8-12 Wh/kg. Very little progress has been made in the past decade in improving either the weight or life of NiCd batteries, although considerable progress has been made in understanding how to use the batteries and how to extend their life through protection and reconditioning. A typical NiCd battery operating at LEO would have an allowable discharge depth of 10-15% and a life expectancy of 3-5 yr.

Battery protection and reconditioning (see F-4), may extend NiCd-battery life to 8-10 yr, or more. Some 20-Ah, 28-V d.c. batteries have already demonstrated operating times of over 7 yr.

Even with such techniques this energy-storage option will continue to be a heavyweight approach. An attractive lighter alternative may be the bipolar nickel-hydrogen (NiH_2) battery under study at NASA-Lewis. This hybrid fuel-cell/battery uses a hydrogen electrode similar to that of the hydrogen/oxygen fuel cell to replace the cadmium plate in the NiCd system. Considerable work has been done by both Comsat and the USAF on a NiH_2 battery system for the relatively low cycle life GEO application, but only bipolar work has been aimed directly at LEO attempting to achieve both long cycle-life and increased cycle depth for the high-capacity energy storage devices needed for a space station. The system (F-4) resembles a fuel-cell stack. Tests of it yield watt-hour efficiencies ranging to 85%, compared to 80% for NiCd. The bi-polar NiH_2 battery should be packagable with a volumetric efficiency as high as that of NiCd but with perhaps twice the specific energy, at around 16 Wh/kg. Since the cadmium plate is the short-life component of NiCd, the NiH_2 system may also have longer life.

Another, even lighter system for energy storage is being pursued at both NASA Johnson Space Center and NASA Lewis. Unlike the hybrid NiH_2 battery, it uses two fuel-cell-related technologies. One fuel-cell stack operates as a power-generation source in the orbit's dark portion and converts reactants (H_2 and O_2) to electricity and water. Another stack operates in the electrolysis mode during the orbit's sunlit part to consume electricity and produce H_2 and O_2 by electrolyzing the fuel-cell-produced water. Called a regenerative fuel-cell/electrolysis (FCE) system, it offers a specific energy of 40 Wh/kg—more than twice the NiH_2 battery's specific energy.

Two of the very interesting potential uses of such technology are to provide emergency O_2 to the life-support system and to provide both H_2 and O_2 as reactants to the propulsion system. Also, since the electrolysis and the fuel-cell stacks are separate items, they can be tailored to the application needed. The first FCE breadboard is already undergoing test and checkout. The basic fuel-cell technology is well advanced, being used as the power source for the Shuttle Orbiter. Achieving adequate life should be the main problem with fuel cell-electrolysis.

Whatever the electrochemical energy-storage system chosen for the initial station, some changeout of hardware on orbit may be necessary. This is not viewed as a particularly difficult task. The 60-Ah NiCd batteries on Space Telescope, for instance, are designed as orbital replaceable units (ORUs) and should provide valuable experience in this regard.

The only non-electrochemical energy storage option under study, the flywheel, could be competitive with the specific energy of electrochemical options. With gas or magnetically suspended bearings the flywheel could have essentially unlimited life. Un-

fortunately, flywheel systems are not sufficiently developed to be serious candidates for the initial space station.

As to power distribution, the system must carry a voltage higher than the standard 28 if reasonable cable weights and distribution efficiencies of 90% or better are to be achieved. Higher voltages entail the primary potential disadvantage of interactions of exposed electrically conductive surfaces and the environmental plasma existing at the space station's operating altitude. The nature and magnitude of such interactions are under study.

The designer also faces an issue in choosing a.c. or d.c. voltage.

Two approaches to higher d.c. voltage have received the most attention. One holds that 135 ±15 Vd.c. is best considering battery reliability and available electronic components. The other advocates twice this level (270 ±30 Vd.c.) on grounds that distribution losses are only half as great and that the component-development problem will not be appreciably increased.

The a.c. choice will be more elusive since the designer may choose among numerous a.c. frequencies. A.c. offers ease of voltage transformation and the possibility of transmission at even higher voltages. On the other hand, the a.c. must be created since the source and storage devices, with the exception of inertial, produce d.c. Whether a.c. has enough advantages to pay for this extra inverter hardware remains to be seen. One interesting possibility is to locate the batteries, solar array, and inverters all on one side of the rotary joint (required for Sun tracking by the solar array) and transmit a.c. through the rotary joint by means of a rotary transformer. The other option is to use d.c. slip rings or roller rings.

NASA has begun a technology program to resolve the a.c.-vs.-d.c. question and to target an optimum voltage range. It should produce the much needed information by mid-1985.

Distribution of power through a utility-style network has certain desirable features. It entails automatic fault sensing and clearing, to keep the number of "customers" losing power to a minimum in the event of a fault. This requires the development of sensing and switching devices that do not yet exist. Also, the requirement to assure adequate power for critical loads as a first priority dictates alternate paths of transmission. Ability to balance the total load among several energy-storage devices to maximize life would also require alternate paths of transmission. One scheme for accomplishing this would be by flexible alternate-path design. Here, the load centers can be fed from any combination of main feeder buses, which lends itself to automated control of the distribution network.

Monitoring of the feeder-bus and load-center network and decisions for reconfiguration represent one of three primary areas of technology effort to provide autonomous control of the entire electrical power system. The other two areas are the energy-storage elements and control of power source. In large measure, these three areas are independent of one another, but sometimes interdependencies within or even outside the electrical power system decide operations. As noted earlier, feeder-bus loads can be balanced through load-center monitoring and switching. Also, some occasions will call for an imbalance in the system. Power quality is another factor that must be considered in power distribution; requirements for transient-free and/or isolated power will need to be accounted for in the autonomous control schemes.

NASA-Marshall has been assembling much of the data for this type of power management under parallel efforts. One seeks to identify the technology issues associated with autonomous control of power systems plus needs for specific technology advancements, as in sensing and switching devices, and for control laws for power-source and energy-storage management. The other investigates the application of "artificial inteiligence" to such complex areas as failure prediction and state-of-health diagnosis. A significant base of empirical understanding already exists through the operation of programmable power processors and power-system controllers. The next two years will be critical in establishing the level of automation that can be incorporated into an initial space station electrical power system and in identifying exact levels of technology risk.

In summary, affordability and manageability represent the foremost challenges in achieving the quantities of electrical power needed by a permanently manned space station. Technology programs in place since 1978 aim to lower the recurring costs of the primary power-system elements and to provide techniques for autonomous control of the overall system. Given sustained support they should yield major advancements over Skylab era techniques for application to a space station designed during the late '80s.

SPACE STATION TECHNOLOGY

COMMUNICATIONS AND TRACKING

Light and IR Will Help Carry High Traffic

By RICHARD M. DICKINSON
Jet Propulsion Lab
California Institute of Technology

Space-station communications and tracking encompass audio-microwave-infrared and optical-frequency subsystems. T-1 lists the many simultaneous potential space station users.

The many nodes of the space-station network range from the ground to nearby space to geosynchronous orbit (GEO), and their positions within the network will progressively change. Agile antenna pointing and tracking will be mandatory for nearly all external links.

The systems listed in T-1 will incrementally grow to at least ten different types of external links—different in range, information content and capacity, duty cycle, line-of-sight angles, RF interference, security, reliability, and carrier frequency. The system must handle simultaneous operation of from 10 to 15 links with up to 30 or more users. Internal links involve voice conferencing, biotelemetry, video, caution and warning, training and recreational, and personal communications.

The current station design thrust—toward increasing productivity and reducing the dependence on a large staff on the ground by providing more of an "operational" station in space—in effect requires an extensive tracking and communication center of its own in orbit. This center will acquire, process and distribute data, and issue commands and data necessary for operation with other space vehicles, notably teleoperated devices and vehicles.

Externally, the system aboard the station will be constrained to operate in a radio regulatory environment of power flux densities sufficiently low to protect established ground-based-equipment users. Competition for frequency assignments is severe. For example, the currently shared assignment of VHF frequencies for intermittent Shuttle extravehicular activity (EVA) may not be extended to the more permanent orbiting station. The long-wavelength VHF radiation is desirable for communicating around objects by diffraction. The existing S-band allocations for near-Earth space communications and tracking already are under pressure to vacate and to move to higher frequencies. Supporting umbilical-free EVA, particularly with extensive TV aids, will necessitate novel techniques and new technology at millimeter or laser frequencies.

Internally, the voice communications system must typically operate in the echo chambers resulting from the structures favored by pressure-vessel designers. The acoustic background noise from the life-support and cooling fans and pump motors can be significant.

The station must be designed and constructed to communicate simultaneously with and track the many vehicles and objects surrounding it in orbit. This requirement for space "traffic control" did not attend previous NASA missions. A vision of the many antennas sprouting from atop a typical airport control tower would not be a bad start for

F-1 Simultaneous operations involving many different vehicles, ranging out to geosynchronous orbit, impose complex communication and tracking needs. New and less expensive equipment will be needed for both the space station and its users.

RICHARD M. DICKINSON is on the staff of the Telecommunications Science and Engineering Div. of JPL and leads the lab's development of deep space communications. He supervised development of the Mercury-Venus 1973 X-band transmitter.

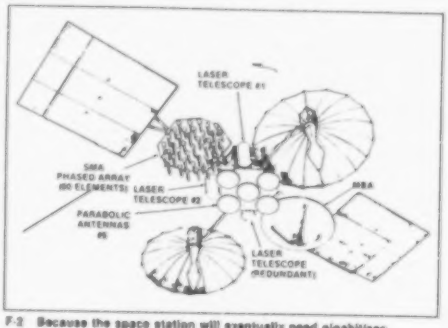
what the exterior of the space station might look like—except that the airport in space is not bounded on one side by the runways! Thus the spaceport "traffic control tower" must look even more like a porcupine to track objects anywhere around the space station. Whereas the Shuttle has 23 antennas, a first count gives the space station over 50 antennas. In addition to Shuttle-compatible equipment at P, L, C, S and Ku bands, the station system will likely have Ka, W, IR and optical-frequency equipment for communications and tracking.

Affordable, space-qualified, steerable phased arrays at RF and optical frequencies are key technology elements for improving productivity and reducing station life-cycle costs related to communication and tracking. Very wide band scientific and applications sensor data-rates also are a problem.

The space station must possess the communications to support the command and telemetry requirements of onboard or captive payloads. Earth sensing, earth resources imaging, astronomy, materials processing, video and other telepresence tasks will require many megabit-per-second channels. Space-station links using existing Shuttle or Landsat equipment to relay signals through the Tracking and Data Relay Satellite (TDRS) can only provide 50 or 300 Mb. TDRS is limited to 300 Mb delivered to the ground at White Sands, N.M. The station obviously needs higher data rate equipment. A more powerful TDRS (F-2) is being studied.

The space station may additionally need to provide the relay equipment for collecting and aggregating telemetery data from a growing fleet of formation flyers around it. That would free the local platforms from having to provide the high-gain, accurate pointing required to make high-data-rate links via TDRS directly. A link of modest pointing requirement and low power should suffice for local platforms and be less expensive to the user. This service could use less expensive wideband equipment at millimeter or laser frequencies. Also, relay links will be needed to TDRS and direct links for data dumps from store-and-forward units direct to users. Uplink color TV and 10^{-9} bit error rate computer data exchanges may require more than the TDRS's 25-Mb/sec uplink.

Regarding traffic control, the Shuttle-era K-band radar can only track a single object at a time to within a minimum range of about 30 m. Technologies exist to track simultaneously several objects at once, but they have not yet taken the form of space-qualified hardware. Also, tracking must extend down to contact or soft-docking ranges. A multifunction radar will be desirable for surveillance of



F-2 **Because the space station will eventually need gigabit/sec** channels, and the TDRS can handle only about 300 Mb, NASA has been studying a more powerful version of the tracking and data relay satellite.

the space around the station. Docking and departure operations will require long-range (2,000-km) acquisition and tracking for traffic control, medium-range (600-km) rendezvous and proximity range, angles and rates, and other orientation data.

A tracking scheme to follow or locate items such as loose tools or construction materials may be necessary to prevent collisions or hazards in the traffic regions about the station. Likewise, we will have to

38-036 O - 84 - 54

decide what to do about these loose objects.

A challenge in the design of microwave and laser links for the space station will be to keep the flux density directed toward personnel and the ground below permitted levels. Combined with the requirement for spherical coverage, this makes the design task particularly acute for EVA operations, but applies also to command and control and tracking while the station is conducting docking and departure operations.

It will be a design challenge to place the many separate antennas and lenses and reflectors about the station external geometry to give adequate overlapping fields of view (FOV) to permit spherical coverage and to radiate unambiguous navigation guide beams and markers. Adaptive arrays with distributed elements may solve the problem. Provisions should be made for distributed elements on modules added later to the station. Control of an adaptive array will require technology developments to produce much more rapid and accurate programs for predicting antenna patterns. Such programs will be necessary to determine the selection, RF phasing, and amplitude weighting of the various signals to be combined to yield the needed simultaneous coverage.

In addition to the radio frequency interference (RFI) and range-change effects on signal strength, the communication and tracking link designs must contend with multipath reflections and blockage from the Shuttle Orbiter and orbit-transfer vehicles (as well as adjacent moving structures such as solar panels). We will need more efficient signal design or coding techniques to permit reliable tracking and communications through the variable delays and interruptions.

A most pressing near-term requirement, however, will be for a voice conferencing system able to handle up to 20 people. Conferences must be controlled by voice inputs, with command-authority recognition and stress monitoring built into hands-free, umbilicalless units. Voice-recognition techniques, equipment, and wireless mikes exist, but the combination and the control software for a man-rated space system have not been demonstrated. IR scatter technology appears attractive.

One approach to spherical coverage involves the use of switched low-gain or "omnidirectional" antennas that broadcast or receive RF energy over a very wide range of angles, (perhaps pi steradians). Since the RF energy is diffused over a wide angle, the intensity in a given direction will be weak. The tendency to maintain performance over the weak link will be to increase the power out of the transmitter. However, this action also increases the power flux density intercepted by the Earth. This constraint limits the link performance. Spread-spectrum techniques reduce the spectral flux density and allow multiple access, but at the expense of complexity. An alternative might be multiple directive antennas for the space station.

Directive antennas require a more precise pointing system and means to acquire and track a target. One option, mechanical pointing of the antenna, requires that the structure to which it is mounted be capable of reacting the steering forces imparted to it. Another option, electronic steering (as with a phased array of low-gain elements), will be more

costly at first, but may prove more cost-effective over the lifetime of the system. Also, wide-angle multiple-beam phased arrays are a highly desirable option to serve many users. The narrow-scan multibeam antenna technology from communication satellites will not meet the needs here.

Many technology options can serve the tracking needs. In addition to tracking information relayed from ground-based equipment or from TDRS, the space station will require its own means of obtaining metric tracking data. Skin-track radar will most likely be used. Beacons will be desirable for enhancing radar return; they will need codes for vehicle identification and other navigation aids such as heading, range to other objects, and orientation. Even passive echo-enhancement devices, such as corner reflectors, may be desirable.

Coherent radio transponders with simultaneous ranging channels can also be used for metric tracking by Doppler and ranging techniques. Interferometric techniques employing antennas located at the extremities of the space station would allow high-angular-resolution tracking of users about the station as well as produce navigation guide beams.

The global positioning system (GPS) may be available to provide position information both for the space station and its users. Individual data links will be needed in this connection.

Lidars (laser radars) will also play a role in tracking.

Tracking from ground-based radars, NORAD data, the consolidated network, and TDRS will be required for objects that pass out of view of the space station or are at extreme ranges.

All this remains to be studied in detail.

Many communication and tracking activities will involve only space-to-space links. These are candidates for optical or IR service. Solid-state lasers and avalanche photo diodes offer the advantages of low power, light weight, long life, small size, and potentially low cost (see F-3). Another benefit of the laser links would be less sensitivity to growing (perhaps factor of ten by 1990) RFI.

Nevertheless, the optical links will have to be designed to accommodate a form of RFI of their own due to blockage and reflections from materials in space, such as adjacent structure and the products of thrusters and expulsions from other processes (e.g., open-loop life support subsystems). Both data storage and alternate routing will be required to handle changes in the optical-link propagation path. Certain coding practices with error-correcting schemes will be applicable.

Thus, a tradeoff exists between optical and microwave systems. Millimeter-wave systems would be the alternative for wide-bandwidth links (due to pressure on lower-frequency microwave systems for other types of service). For military payloads, laser links will provide a degree of security against interception because of their narrow beams.

High-data-rate experiment telemetry that does not require real-time return can be recorded aboard the space station and returned on the next Shuttle flight. Data could also be processed aboard the station to reduce the quantity to be transmitted. Alternatively, the data could be sorted and dumped at high rate during the next available pass over the user's premises if it has compatible receiving and tracking equipment.

A major technology challenge will be to reduce the cost of electronic beam steering for both RF and optical-frequency phased arrays. Techniques such as monolithic microwave integrated circuits and VLSI computational modules will help, but additional cost-effective fabrication and assembly techniques will be required, particularly for power generation and phase-shifting devices. Techniques will be needed for fabricating and cooling two-dimensional arrays of solid-state laser diodes.

A great challenge will be to produce more efficient and lower cost millimeter wave devices by photolithographic techniques. Such equipment would benefit the wideband, high-data-rate links required on space station.

Similarly, we will need faster algorithms for producing accurate antenna-pattern prediction codes. Success would benefit FOV architectural design and adaptive tracking and communications.

Ability to design and produce lower-cost dual or multifrequency antennas would allow fewer pressure-hull penetrations and less real estate devoted to antenna farms.

In summary, the space station will initially employ the communications and tracking equipment and systems designed for past space vehicles, such as the Shuttle Orbiter, Landsat, TDRS, and some commercial and DOD satellites. But before long better systems will be needed. Constraints will force a move to higher RF and optical frequencies. The greatest challenge will be to develop *affordable* RF and laser electronically steerable phased arrays. These will increase productivity and permit the low life-cycle costs needed to support spherical-coverage operations for space traffic control, EVA and teleoperations.

The research described in this article was carried out by the Jet Propulsion Laboratory, California Institute of Technology, under contract with the National Aeronautics and Space Administration.

SPACE STATION TECHNOLOGY

CONTROL

Demands Mushroom as Station Grows

By STEPHEN Z. SZIRMAY
Jet Propulsion Lab
California Institute of Technology
and
JAMES BLAIR
NASA Marshall Space Flight Center

The initial space station will be composed of structurally rigid and nonrigid modules, rotating elements, and flexible appendages. As the station evolves, the configuration will change to reflect new missions, embracing both old and new elements. The station will experience environmental disturbances from the atmosphere, gravity gradient, the magnetic field, and solar radiation. It will also occasionally experience self-generated disturbances —docking forces, vibration from construction, and various perturbations from crew motion, station venting, payload articulation, and attitude or reboost maneuvers.

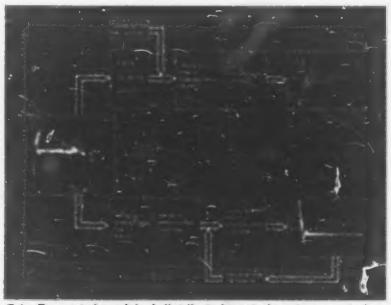
Control functions for the original space station may include attitude control, docking and berthing control, and system monitoring and management. As the space station evolves and mission objectives become more ambitious, control functions will multiply to perhaps encompass these:

- Attitude control and stabilization.
- Large space structure controls.
- Articulation control.
- Autonomous navigation.
- Space traffic control.
- Systems monitoring and management.
- Manipulator control.
- Teleoperator maneuvering system control.

STEPHEN Z. SZIRMAY, far left, manager of the Automated Systems Section, has been with JPL since 1956. A graduate of New York Univ., BSEE, 1954, he leads R&D in control of large space structures, robotics and teleoperators. JAMES C. BLAIR, deputy director, Systems Dynamics Lab, joined NASA-Marshall in 1963. A member of AIAA s Guidance and Control Technical Committee, he holds M.S. and Ph.D. degrees in electrical engineering from the Univ. of Tennessee.

Levels of control technology for the space station will depend on its evolution. Current control technology may suffice to fly the initial space station. But in order to ensure the ability of the station to grow without expensive retrofit or control redesign, the original control system must have architecture and interfaces compatible with future control technology. As structural elements are added, modular/distributed control will be required. When the configuration complexity, nonlinearity, and flexibility of the station become significant, onboard system identification techniques will be required to provide adequate information about configuration and dynamics. Adaptive techniques will probably be needed to control station dynamics.

Advanced control technology will be needed not only to enable graceful evolution, but also to gain



F-1 Truncated model of distributed control system must show the predictable performance indicated in the bottom part of diagram. Top indicates unstable or unpredictable behavior.

better performance, higher reliability, lower cost, and lower risk. It will be pivotal in developing automated systems that reduce ground support.

Principal challenges in these areas of control system design will be:

- Automated management of a highly complex man/machine system.
- Precision pointing and stabilization for a nonrigid structure growing progressively in size and complexity.
- Modular systems of high reliability, long life.

These needs call for hierarchical control, distributed modular control, autonomous real-time systems identification, vibration control, adaptive control, intelligent man/machine interfaces, and high-reliability, long-life hardware. T-1 enumerates all advanced technologies required. These technologies must be evaluated to demonstrate performance and

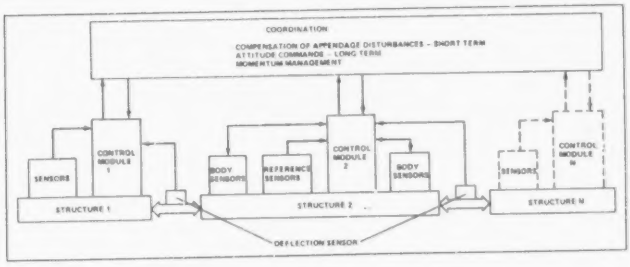
Multiple vehicle control hierarchy
Rendezvous/approach management
Docking control

F-2 MODULAR CONTROL CONFIGURATION



identify risk and life-cycle cost.

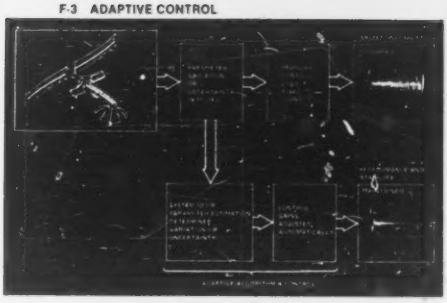
Distributed control techniques are used to actively stabilize large space structures which must be characterized by models having very large dimensions. Current approaches use a truncated model of the large space structure. Evaluations with the original, very large dimensional model, often show unpredictable or even unstable performance (see top of F-1) due to model truncation errors. An advanced distributed control begins with the *infinite* dimensional model of the large space structure. The initial distributed-control law obtained will also be dimensionally infinite. This control law must be truncated to a finite dimension and the truncation must yield predictable performance as illustrated on the bottom of F-1.

Modular control (F-2) represents an attractive way to add space-station elements efficiently with minimum impact on the existing control system configuration. An individual module would have its own control subsystem (actuators, sensors, control computer, etc.) and a "supervisory" controller would coordinate the modules. Including a new module would then require only addition of that subsystem and reinstruction of the supervisory control. Progress on this concept has been encouraging. A system with certain restrictions has been simulated and is being improved.

The initial dynamic model used in control design will contain uncertainties in structural stiffness, damping, and fundamental vibration frequencies, and the station will be changing dynamically during its operation. These variations may degrade the performance of standard control designs, to the point of instability (see top of F-3). To get around this problem, system identification and adaptive control can be used. System identification means determining type order and parameters of a system from measurements. An adaptive controller can update control and filter gains and maintain system stability as illustrated on the bottom of F-3.

The station's control system will likely include devices such as control-moment gyros, or reaction wheels which absorb external torques in the form of angular momentum. These devices work best when the external torques have strong cyclical components as do aerodynamic and gravity gradient torques. F-4 shows effect of aerodynamic center of pressure on momentum storage. Storage requirement is given in terms of the number of 3000-nms control-moment gyros (CMGs) required to fly the illustrated platform in an inertial orien-

F-3 ADAPTIVE CONTROL



tation with the longitudinal axis perpendicular to the orbit plane.

Large solar arrays dominate the aerodynamic forces, and the torques thus depend on the displacement of the system's center of mass from the center of pressure of the solar arrays. Data are given for payloads that cause displacements of 7 and 16 m. Since the aerodynamic torque varies with the ambient atmospheric density, and the density depends not only on altitude but also on solar activity, F-4 shows a range of CMG requirements. The upper bound for each configuration represents the requirement during periods of high solar activity. The lower bound applies to periods of low activity. As these atmospheric conditions become better known, the operating limits of the control system can be defined better.

Because of the sensitivity of large configurations to the many environmental moments, station geometry selection should consider momentum storage requirements. For maximum efficiency, the momentum-management system should try to offset one disturbance with another and thus minimize the storage requirements.

T-2 indicates typical momentum-desaturation capacity of several sources. Magnetic torquers are versatile, but have power and weight penalties. Gravity gradient and aerodynamic torquers have axes limitations, depending on the mode and orientation flown. Because the payload and experiment requirements are not known yet, no cyclical momentum terms are planned for a momentum-desaturation scheme. Effort should be concentrated on deriving a three-axis momentum desaturation technique using a combination of all three sources. Technology development will be needed for automating the momentum-management system, to reduce ground support requirements.

A hardware and software test bed will prepare the emerging technology for application. The guidance, navigation and control (GN&C) test bed will be an evolving simulation facility permitting selective substitution of actual GN&C software and hardware components in place of computer simulation elements. It should identify issues that drive design and performance requirements, specifications, and

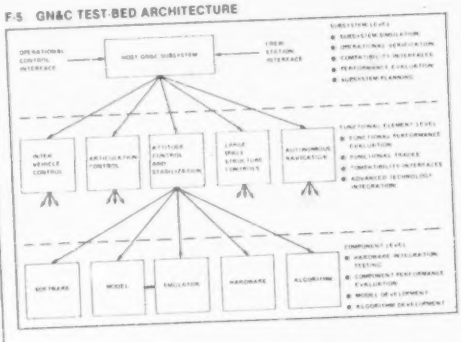
critical interfaces, and allow standardizing an approach for test and evaluation of GN&C options. Also the test bed will provide a means of transferring GN&C technology into the station development program throughout the life of the station.

In construction, the GN&C test bed will take a hierarchical form, paralleling the definition of the entire GN&C system (F-5). At each level the requirements on the constituent elements will be levied in the form of simple models designed to operate together as software modules within the simulation program. The modules will be usable independently and could be developed in isolation as long as the interfaces and functions are preserved. Modules within modules will be appropriate as long as they do not violate nesting constraints within the hierarchical structure. Each module in this early test bed will represent an identifiable element of the GN&C system and, depending on its depth within the model, could represent anything from a piece of hardware, such as an actuator, to a subsystem, such as an articulated instrument platform.

Another feature of the test bed will be its ability to substitute any given module and all of its nested constituents with a functionally similar but simplified version of the same element. Thus, not only will it be able to run subsets of the model independently, but also run the model at any level without the overhead associated with extraneous details.

The attitude stabilization and control "sub" test bed will be comprised of facility computers, environment simulators for control system hardware, and flight-type control hardware and software, including sensors, actuators, and flight-control computers. It will be used with increasing levels of fidelity. In early phases of assessment, its computers will allow total simulation. Hardware and environment simulators, such as the three-axis motion table, can be substituted for computer math models as development progresses and the test bed achieves higher fidelity. Tasks to be performed on the sub-test bed include assessment of control laws—taking in structural stabilization, momentum management, and distributed and modular control—derivation of component requirements, prototype testing, fault isolation, testing of components, system integration and interface testing, and software checkout.

F-5 GN&C TEST-BED ARCHITECTURE



Major challenges in control technology development arise from the need to cope automatically with the highly complex space station, the configuration of which will be changing in orbit. To meet these challenges, significant advances in distributed control, adaptive control, modular control, system identification, fault-tolerant reliable hardware, and other technologies are required.

The test bed will widen options for GN&C development by bringing technology elements to a state of readiness and evaluating designs on a common basis. It should efficiently bring technology into the mainstream of station development—ensure "technology-optimal" design for growth, high performance, and minimum life-cycle cost.

This NASA lab will be testing technology for a partially closed life-support system aimed at 1986 design decisions and likewise will ready regenerative equipment for the anticipated eventual closed system.

SPACE STATION TECHNOLOGY

ENVIRONMENTAL CONTROL AND LIFE SUPPORT

Partially Closed System Will Save Big Money

By WALTER W. GUY
NASA Johnson Space Center

The environmental control and life support system (ECLSS) for the space station embraces basic requirements for atmospheric revitalization, atmospheric control, cabin thermal control, metabolic water, hygiene and waste, EVA support, and galley support. The first three maintain the living environment. For atmospheric revitalization, CO_2 must be continuously removed from the atmosphere together with other metabolically-produced gases. Oxygen used in the metabolic process must be replenished along with the oxygen and nitrogen lost due to cabin leakage. Atmospheric control mainly concerns cabin pressure and the composition of its constituents along with the monitoring of atmospheric trace gases and airborne microbiological contamination. Thermal controls remove heat from the cabin, ventilate it, and set humidity.

Metabolic water, both required and produced, must be collected, processed, and readied for reuse. It involves collection, reclamation, sterilization, quality monitoring, and stowage. Sources of metabolic water include perspiration, respiration, and urination. Other sources associated with crew hygiene include hand washing, bathing, oral hygiene, and laundering. Solid and liquid wastes associated with life support must be collected and processed. So must wastes from the galley. This includes refrigeration and freezing equipment, ovens, food processes, trash compactors, and dishwashers. The galley thus interacts with the metabolic and hygiene-water areas. Food and beverage preparation requires potable water. Clean-up requires water from the hygiene area while adding to waste water to be processed.

WALTER W. GUY (M), chief of the Crew Systems Div. at the NASA Johnson Space Center, has responsibility for developing spacecraft environmental and life support systems and astronaut intravehicular and extravehicular support equipment.

ECLSS also supports extravehicular activity (EVA), providing water, oxygen and waste stowage for the space-suit life support system, recovering consumables from EVA byproducts, and scavenging atmospheric gases from the vehicle's airlock.

Degree of ECLSS Closure: It is not obvious which of the crew's needs should be provided from the Earth (with the associated logistics penalty) or recovered in orbit from metabolic byproducts. In other words, what degree of system closure will be "optimum"? Arriving at a judgment involves tradeoffs of program risk, weight and volume, and life-cycle costs, and includes a fundamental life-support-system decision: whether to regenerate food from wastes. Current space-station planning involves a 1986 phase-C/D start. We lack the technology for food regeneration. Attempting to secure it by 1986 entails a relatively high risk. Thus supplying food from the ground must be considered an "optimum." In contrast to food, the other basic life-support requirements can be generated on board the space station with technology now being demonstrated. In fact, any of several concepts can provide oxygen, carbon dioxide removal, and water for drinking and washing.

Taking weight and volume as the primary decision factors brings the launch and logistic penalties of providing life-support requirements to the forefront in the determination of "optimum." Ground rules should be established in order to compare penalties for "open" and "partially closed" life support.

Although the space station has not yet been defined completely, the following conditions represent a realistic set of such groundrules: crew size of eight, resupply interval of 90 days, initial launch includes expendables for first resupply interval plus 30-day contingency, drinking water provided at 7.86 lb per day per person, wash water for morning hygiene at something less than a pint, and the same for two additional handwashes per person per day.

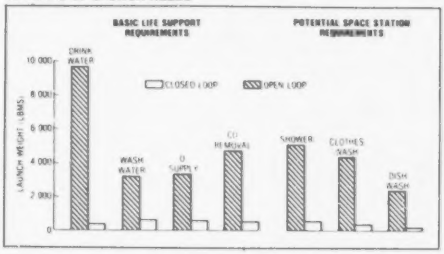
Recent studies have taken the Shuttle design as state-of-the-art for estimating tank-storage penalties, packaging weights, consumable weights, and metabolic/hygiene requirements. Weights for re-

generative life-support subsystems (their process efficiencies and expendables requirements) were taken from advanced laboratory hardware available today. This laboratory hardware was not designed to meet flight weight specifications so the comparisons to be presented should be conservative.

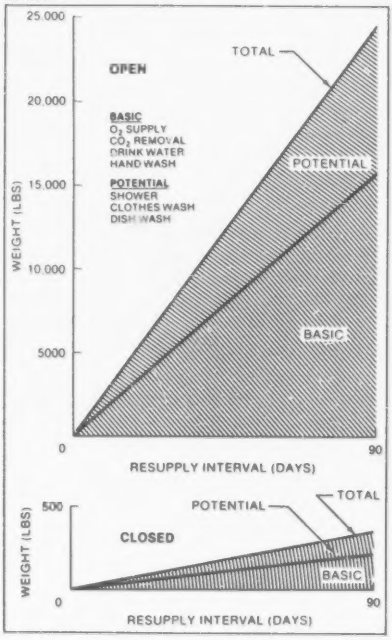
F-1 and F-2 compare open and partially closed life-support launch and resupply weights for basic requirements using the groundrules given above. A typical open-loop, Shuttle-type life-support system incurs a dramatic penalty over a partially closed system of today's technology. From an overall standpoint, a partially closed system will save almost 20,000 lb of launch weight and a further 15,000-lb saving at each resupply interval.

Several additional requirements concern onboard regeneration. Water which enables the crew to shower every other day as well as water for clothes-washing and dishwashing could be recycled by water-reclamation systems using existing technology. Although perhaps not mandatory, water reclamation would eliminate hygiene wet wipes, disposable clothes, and disposable trays and utensils for food service and thus save weight and volume—some 10,000 lb more in initial launch weight and at each resupply interval.

F-1 OPEN VS. PARTIALLY CLOSED LIFE-SUPPORT SYSTEMS IN TERMS OF LAUNCH NEEDS



F-2 RESUPPLY WEIGHT FOR OPEN VS. PARTIALLY CLOSED SYSTEMS

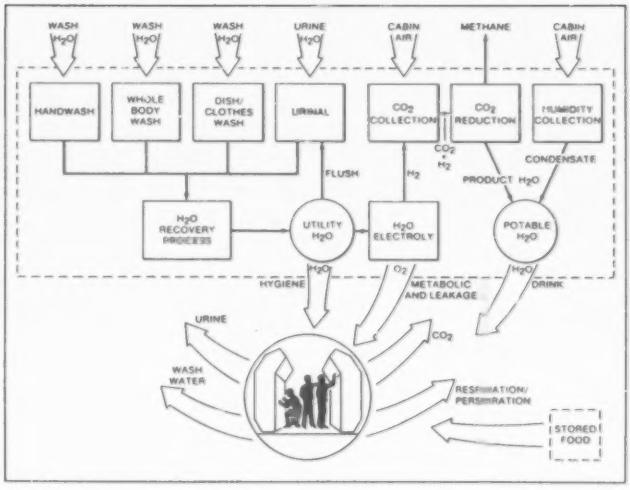


This appraisal strongly suggests that a partially closed life-support system would be "optimum." However, life-cycle costs must also be evaluated. Assuming that a single Shuttle launch costs about $60 million for a 60,000 lb payload, each pound in orbit costs nominally $1000. A partially closed life-support system thus saves about $80 million by the end of the first year of space-station operation. We conservatively estimate that the design, development, test, and evaluation (DDT&E) for a partially closed life-support system would cost $80 million more than for an open-loop system. Therefore, over the first 10 years of space-station life the partially closed life-support system will save over $700 million (even discounting inflationary effects).

In short, program risk, weight and volume, and life-cycle costs favor partial closure of the life-support system. F-3 depicts the concept for a partially closed life-support system. This scheme gives the crew high-quality water to drink and and recycles the nonpotable wash water. It recovers water from washing hands, body, dishes, and clothes and flushing the urinal. Excess water from the recovery process is electrolyzed to provide metabolic and leakage oxygen. Hydrogen from water electrolysis is used, as needed, in the CO_2 collection and reduction processes, which produce methane (or carbon) and chemically-formed water. The crew drinks electrolysis water and moisture condensed from the atmosphere during humidity control.

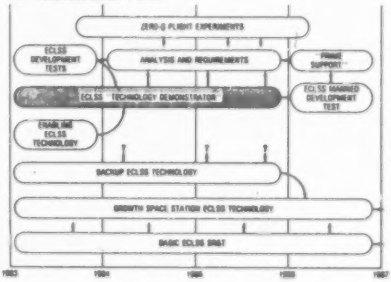
ECLSS Configuration: Other space-station design "parameters" can affect the configuration of the environmental control and life support system. Consideration is being given to the use of a regenerative fuel cell to augment solar arrays for nightside power. The fuel cell in this mode does not

F-3 PARTIALLY CLOSED SCHEME UNDER DEVELOPMENT



consume reactants; the water it produces is subsequently electrolyzed to regenerate the reactants for the next darkside pass. The crew could also use this water. For a nominal 50-kW nonregenerative fuel cell almost 90,000 lb of reactants would be required each 90-day resupply interval. Thus, the byproduct water provides more than six times the amount of water needed for drinking, crew hygiene, and clothes- and dishwashing. With so significant a weight penalty for reactant resupply, the open-loop fuel cell would *not* be an intuitive choice for space station power. However, should large-scale solar-array technology falter or the evolving needs of the space station dictate fuel cells as the electrical power system, the ECLSS would not require any water-reclamation subsystems.

F-4 TECHNOLOGY PLAN



The reality of funding availability for technology development, the implied risk of new technology to project cost and schedule, and the promise that evolution means acceptance to change over time might delay initial incorporation of the "optimum" ECLSS. Early during buildup of the space station a small crew could use a flight-proven Shuttle-type system. Only when the station has a larger permanent crew would the advanced, partially closed system be required.

Two aspects of each new ECLSS subsystem concept must be evaluated as the station begins to build up. First, is the subsystem efficient in terms of energy or expendables, or more reliable than a subsystem already on board? If so, can it be configured to meet the interfaces of the already installed system? Secondly, does the new subsystem concept perform previously unavailable functions? Will it improve process flow without a redesign of the basic system?

Technology Challenges and Opportunities: The ECLSS presents two main technology challenges: to achieve technology readiness for design and to prove that a firm commitment can be made to technology which has never flown in manned spacecraft. These challenges entail several subtle issues of automation, maintainability, commonality, and reliability. They must be resolved in a way that allows

space-station crew to treat the life-support system like a utility requiring only preventative maintenance, and not have it occupy a primary position in their day-to-day activities, simply because it must necessarily sustain their lives.

Each challenge may also be viewed as a management opportunity. The need to achieve technology readiness presents a chance to plan and organize a technology program sharply focused on space-station requirements. The program will bring the technology beyond laboratory demonstration of critical functions or characteristics through testing of an engineering model in a simulated or, if necessary, the actual space environment.

With the near-in, 1986 space-station start, only subsystems now in some stage of development will have any real opportunity.

The second technology challenge, proving technology readiness, encourages systematic demonstrations. Three are planned. In the first, a laboratory demonstration of the long-life characteristics, each test article will be a scaled-down subsystem embodying the "heart of the process." This family of life-test modules will be run continuously throughout 1983, 1984, and 1985, with periodic checks to measure any loss in process efficiency. By the 1986 space-station start, much data will be available to instill confidence in the life characteristics of the candidate subsystems. The second demonstration, however, will be the most important "proof." It involves extending the current subsystem-level testing to unmanned integrated testing and then a manned test of a prototype ECLSS in a closed-door chamber. The third will subject concepts potentially sensitive to zero-g to flight tests.

All three demonstrations being successful, final design can commence with good confidence.

F-4 describes the overall technology plan. An integrated ECLSS—the Technology Demonstrator—will be used in the manned test demonstration discussed above. Definition of subsystems for the Technology Demonstrator has begun. Concurrent with this are three separate technology activities. The first provides backup concepts in each important ECLSS area. The second covers technology potentially important to evolution of the space station. (Backup subsystems for the Technology Demonstrator will move to this activity if not required to support Demonstrator development.) The third, the basic R&T, leads to attractive options for the more distant future. This approach supports prime-contractor efforts early in the program. With proper coordination, the integrated ECLSS manned test bed can be used to generate development data for the prime contractor.

SPACE STATION TECHNOLOGY

SYSTEMS AND OPERATIONS

Living with Complexity and Growth

By W. RAY HOOK
NASA Langley Research Center

For the space station, nine working groups will oversee most of the research and the development of technology needed in nine separate disciplines. The complexity of the space station and its interactions with other space and ground systems calls for a tenth group to check on how the technology works together.

The space station will be supported by the Space Shuttle and a ground operations group with the Tracking Data Relay Satellite System tying the three together. The space station will host other spacecraft (F-1A) such as orbital-transfer vehicles, science and application free flyers and platforms, and teleoperator maneuvering systems. The crew also will carry out an impressive array of experimental and operational functions. Since the space station will likely be added to (F-1B) and old portions updated for at least 10 years after it is first put into orbit, careful attention must be given to the interfaces between elements of the station to prevent costly development and operational work-arounds later.

Complexity of the space station interfaces, need for evolutionary design, and for low development and operational costs are main concerns.

Growth in size and exchanging new technology subsystems for old ones can be made easier by developing computer emulation of the interfaces. Growth hardware can then be checked for compatibility before it is launched into orbit. It will be examined not only for form, fit, and function, but also to avoid unacceptable interactions with the complete space station. In the past, systems-level verification has been done using the actual flight system before launch. The same cannot be done for the space station, for it will grow on orbit.

W. RAY HOOK, (M), directs NASA-Langley's system analyses of large space antennas and permanently manned orbiting space stations. Earlier he contributed to systems studies of Skylab and Spacelab. Hook is a member of the AIAA Space Systems TC.

New-technology replacement subsystems may perform required functions in a radically different way. The interfaces must transmit whatever functions are necessary, independent of the technology incorporated into a subsystem. This approach to interface design has been called "technological transparency," which may be ensured by minimizing subsystem interactions through the use of a high degree of hardware modularity and a corresponding distributed data system.

The working group has the job of conducting systems analysis, interaction, and sensitivity studies across disciplines and architectural options. It will depend on computer-aided design and analysis.

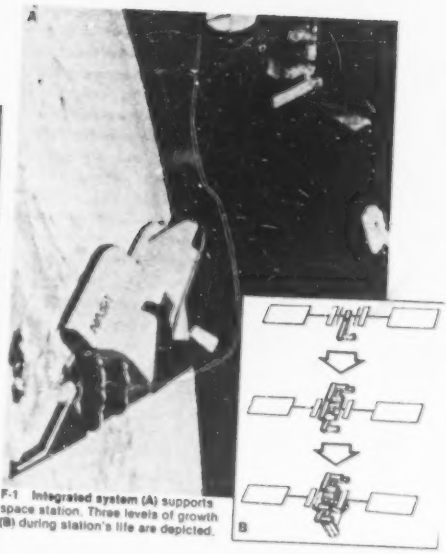
New technology is necessary for deployment, assembly, checkout, and operation of the original station, and deployment, mating, and checkout of modules sent up later. The long-range goal is to develop standardized payload checkout and operation with a minimum of ground crew involvement.

Assessment of the needs for and the benefits from autonomous operations must be evaluated broadly—across the space station system. The results of this assessment will be periodically fed to the other discipline working groups to assist their selecting technology goals that can significantly reduce costs. Efforts have begun to develop generic fault detection, isolation, and correction techniques that could simplify on-orbit operations, maintenance, and repair. Engineering assessment methods have to be worked out for making cost-effectiveness trade studies between reliability—gained through such measures as high-quality parts, or extensive screening and testing—ease of maintenance, and design for fault isolation and correction to obtain the lowest overall life-cycle costs.

Guidelines and standards for checkout, repair, servicing, and deployment of spacecraft from the space station by both EVA and teleoperators will be developed to identify technology gaps. Construction, erection, and assembly operations will be studied to evaluate the degree of automation desired and the types of equipment required. The technologies necessary for advanced manipulators, teleoperators, and robots will be defined. The goal is to capitalize on man's ability on orbit and to maximize his effectiveness in operating machines.

The working group is also responsible for a variety of tasks that do not relate directly to the disciplines of the other working groups. The tasks include alternative rescue and escape strategies, integrated hydrogen-oxygen system analysis, and computer-aided design and analysis application to systems trades.

Alternate rescue and escape strategies range in complexity from provision for safe havens on board the space station to remote space-orbital shelter or orbit-based rescue, to reentry escape or ground-based rescue using the Shuttle. Economics does not allow keeping a Shuttle Orbiter at the space station. This will be a significant change from the practice of keeping an Earth-return vehicle on station at Skylab and the USSR Salyut. This study will develop crew safety philosophy and criteria, assess potential threats to crew safety suggested by mission scenarios and associated station architectures, and evaluate the effectiveness of the various escape and rescue strategies to meet the desired criteria at reasonable cost.



F-1 Integrated system (A) supports space station. Three levels of growth (B) during station's life are depicted.

An integrated hydrogen-oxygen system promises the greatest reduction in resupply costs of any single development. Scavenging excess fuel from the Shuttle's internal and external tanks and using leftover Shuttle payload for fluid tankage could supply hydrogen and oxygen for propellants, fuel cells, and life support. This approach could reduce resupply and simplify fluid management. Advances in cryogenic fluid management and storage technology are the keys. They would also further the development of orbital-transfer vehicles, teleoperator maneuvering systems, and high-energy upper stages.

Additional technology would be needed for regenerative fuel cells, gaseous hydrogen/oxygen propulsion, and life-support systems. Fuel cells could be used as primary fuel cells only, as primary cells coupled with a photovoltaic array, or in a fuel cell/electrolyzer combined with a photovoltaic array. In the first, two arrangements the cells could

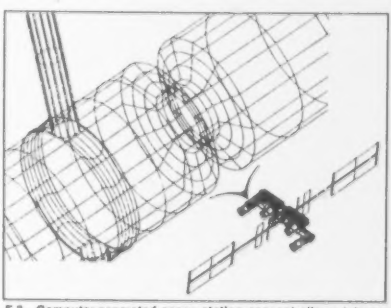
Copyright © 1983 by the American Institute of Aeronautics and Astronautics.

operate on propellant-grade hydrogen and oxygen scavenged from the Shuttle tanks. The regenerative system (F-2) would use water as the fuel for the electrolyzer. Water could be resupplied routinely by the Shuttle using excess payload capacity. In these concepts the fuel cell produces primary power and may be integrated with the life-support, thermal management, and propulsion systems for gains in cost savings and operational simplicity.

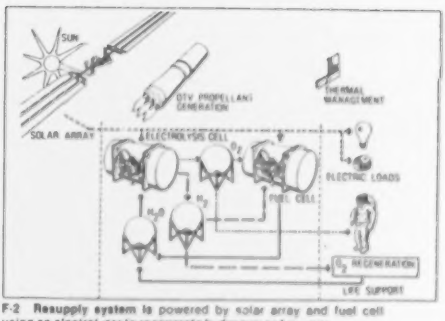
In the regenerative system, water output from the Environmental Control/Life Support System would be electrolyzed to make oxygen to go back into the life support system. The primary cell would convert oxygen and hydrogen into water for use in the thermal management system and as energy for the space station electric loads. Similarly, water could be delivered to orbit to be turned into hydrogen and oxygen for space-station-based, orbital-transfer vehicles. A new technology refrigeration and liquefaction system would be required to convert the gaseous fluids to the cryogenic state.

The discipline working groups have identified a long list of technology that needs to be developed. The next step will be to better quantify the payoffs from individual technology advances, understand the interactions of advanced technologies across disciplines and subsystems, and better define how they affect space station growth. Then priorities can be established.

A tool for setting these priorities will be the computer-aided design and analysis system called Interactive Design and Evaluation of Advanced Spacecraft (IDEAS) under development by NASA-OAST at Langley Research Center. The system integrates conceptual design and analysis software for large orbital spacecraft. Most computer codes for multidisciplinary analysis of large spacecraft had been collections of long-running, single-discipline,



F-3 Computer-generated space station concept allows interaction between program modules to design complete system.



F-2 Resupply system is powered by solar array and fuel cell using an electrolyzer to regenerate hydrogen and oxygen.

highly generalized codes that did not have the breadth needed to perform complete parametric tradeoffs of the total spacecraft, its supporting subsystems, and the on-orbit operational environment. With the new system engineers will be able to rapidly evaluate system concepts and technology needs for future large spacecraft more cost-effectively with less labor. The system consists of about 40 technical modules, efficient executive and data/file management software, and interactive graphics display programs. Technical modules include structural synthesizers and finite element modules; spacecraft dynamics and control system analysis; large-area drag, gravity gradient, and solar pressure environmental loading algorithms; structural element design; subsystem design and data base; habitable module support systems; operational analysis; and performance, cost, and reliability algorithms. The automated computer-aided design and analysis system allows interaction between modules and is used to create a complete system design (F-3) by putting in mission requirements and specified subsystem characteristics. The design is rapidly synthesized and evaluated, and performance characteristics are determined.

With the system, competing space station and mission designs can be rapidly evaluated, performance/cost tradeoffs made, technology sensitivity analyses carried out, and competitive technologies evaluated. These evaluations can maximize the return from the technology investment.

The success of a new space station will not be measured until many years after the station has gone on orbit. A primary measure of its success will be the degree to which the station has become a major element in a fully integrated space system. Focusing early on an integrated systems and operations design will help ensure this success.

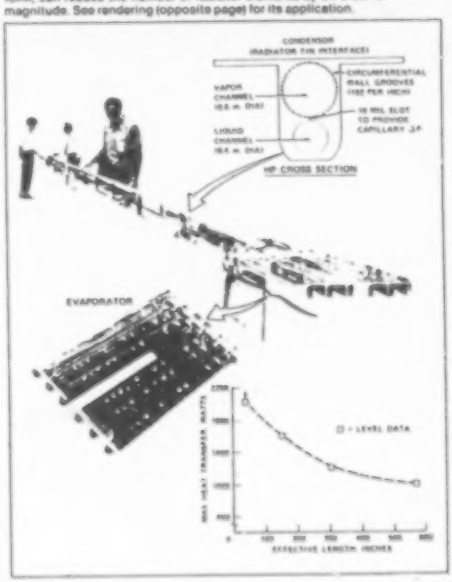
SPACE STATION TECHNOLOGY

THERMAL CONTROL

Heat Buses Will Operate Like a Public Utility

By W.E. ELLIS and J.G. RANKIN
NASA Johnson Space Center

This 2 kW monogroove heat pipe, already tested in prototype form, can reduce the number of radiator elements by an order of magnitude. See rendering (opposite page) for its application.



Multi-year mission duration, large quantities of waste heat to be dissipated, and the anticipated large variety of payloads and missions all will be major drivers in the design of space-station thermal control. The space station especially must be able to handle widely varying heat loads, sites of heat sources being changed by the crew as dictated by mission objectives, and, while continuously operative, evolutionary growth.

Active thermal control requires long-life heat rejection, highly versatile thermal transport, and efficient system integration.

Heat rejection focuses on the requirements for final transfer of waste heat from the spacecraft to the ambient environment by radiation. Any concept for a large manned space station will need large deployed radiators for heat rejection. By a significant margin, the radiator will be the largest and most exposed portion of the space-station thermal system. Improvements in radiator size, complexity, and efficiency will be mandatory to gain the needed performance.

Transport requirements encompass the collection and movement of thermal energy from the space station's heat sources to the radiator heat sink at required temperature levels. Current thermal subsystems require precise ordering of equipment within the thermal-transport circuit to maintain temperature control (i.e., equipment requiring cold temperatures must precede in the circuit equipment that can tolerate higher temperatures). Modular growth of the space station will require it to accept multiple heat loads of various magnitudes, heat-flux densities, and locations without causing adverse interactions. That is, the station will need a highly versatile thermal "utility" or bus system analogous to a municipal public utility. Changes in location or load of individual subsystems and payloads must minimally affect the utility's ability to serve the remaining heat loads.

Current thermal systems make large use of electrical heaters and require much crew involvement to

W.E. ELLIS, far left, directs the Systems Engineering Br. of the Crew Systems Div. at NASA Johnson. He has led NASA's in-house advanced thermal technology development program for the last 10 years, particularly heat pipe applications to spacecraft. J.G. RANKIN, senior thermal control system project engineer at NASA Johnson, joined NASA in 1971 to work on the Shuttle active thermal control system and EVA mobility unit. Previously, with Vought, he had a hand in thermal control of Apollo and Skylab.

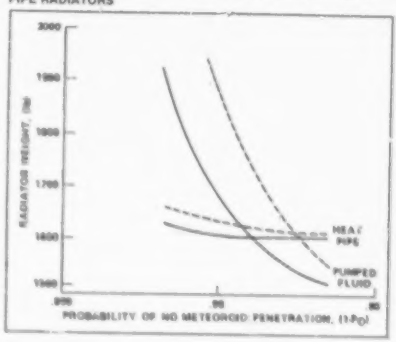
change the system's operating configuration as power profiles and heat loads change and system failures occur. The space-station thermal system must make judicious use of waste heat (minimize or eliminate electrical heaters) and minimize crew involvement by using an automated thermal utility system. Operational life and costs will be key issues in design.

In a decentralized thermal system, each module of a space station would collect and reject all of the waste heat generated with no module interconnects necessary. Each module would have complete flexibility in the selection of its control temperature and in how its heat gets rejected. It would be possible for modules to use different working fluids and devices. However, the decentralized approach would not allow waste heat from one module to be used by another. Also, since each module rejects its own heat, it would need its own radiator and thus impose its own orientation and location restraints on the overall vehicle. Since several modules may require radiator deployment to achieve heat rejection, overall thermal complexity and weight of the system would tend to be high.

In contrast, a centralized thermal system would allow maximum use of waste heat from one module by another. It would minimize the size, and thus the cost, of the thermal system. Because the system could take advantage of the "peaks and valleys" of the module heat loads, it could be sized for an average vehicle heat load and thus be significantly smaller overall than a decentralized system. A centralized system also allows efficient radiator design and positioning "out of the way."

In the centralized system heat must be transported across module boundaries. Several methods of doing this have been investigated, such as direct fluid interface through fluid disconnects, typical compact heat exchangers with connectors, and contact heat exchangers. The latter two would not require intermixing of module heat-transport fluids. The contact heat exchanger has the additional advantage of entirely eliminating fluid connections, thus improving reliability and providing more flexibility in thermal-control design for the individual modules. Also, the contact heat exchanger simplifies adding new modules to the station during build-up and routine equipment installation. Its pri-

F-2 METEOROID SENSITIVITY OF PUMPED FLUID AND HEAT PIPE RADIATORS



mary disadvantage is a somewhat higher temperature drop across the interface.

All space-station concepts envisioned to date require large deployed radiators to reject waste heat. It is necessary to minimize the size of the radiators not only to hold down weight and cost, but also to simplify design and operations. Smaller radiators simplify launch and construction, vehicle attitude control and stability, maintenance, payload space-sensor viewing, resupply-vehicle docking, and micrometeoroid protection.

In general, for minimizing size, radiator panels should travel edge-to-Sun as much as possible. F-1 illustrates radiator-area sensitivity to the external thermal environment. Gimbaled continuously away from solar flux and Earth flux as much as possible, the radiator can have an area as much as 60% less than one of fixed orientation. The figure also illustrates another advantage of a gimbaled radiator; not being directly exposed to the Sun, its thermal coating would degrade less.

High reliability for long-duration missions can be achieved with a Shuttle-type (separate-tube) radiator if it is adequately shielded, but the system would be heavy and complex because of redundant plumbing, pumping, and valving. To handle 100 kW of heat rejection an existing Shuttle-type fluid radiator system would require over 19,000 ft of tubing consisting of over 1500 individual pumped fluid tubes, over 50 fluid manifolds, over 75 isolation valves, fluid disconnects, and fluid swivels (or flex lines).

A radiator using multiple independent heat pipes offers an attractive means to eliminate most single-point failures. Loss of a single heat pipe would not be catastrophic. The heat-pipe radiator would thus need much less meteoroid protection. Prototype heat-pipe panels have been designed, built, and tested. F-2 compares the weight of conventional fluid-type radiators and heat-pipe radiators for a long-life space station. The implications for micrometeoroid protection are clear. Heat pipes can also greatly decrease system complexity. A single heat pipe can passively reject as much as 2 kW of heat. Thus as few as 50 could handle a 100-kW space station.

A high-capacity monogroove heat pipe (opening illustration) has been developed to simplify space radiators. It separates the heat-transport and heat-transfer functions so that they can be optimized separately to transport 600,000-1,000,000 W-in. with high film coefficients. It combines the advantages of axial grooves, such as simple construction and large liquid and vapor areas, with the high heat-transfer coefficients of circumferential wall grooves. (The basic monogroove design contains two large axial channels, one for vapor and one for liquid. The small slot separating the channels creates a high capillary pressure difference that, coupled with the minimized flow resistance of the two separate channels, gives the high axial heat transport. High evaporation and condensation film coefficients are provided separately by circumferential grooves in the vapor channel walls.)

The space-station designer must decide to deploy or to construct the radiator space. A pumped-fluid radiator would probably require deployment, because of the complexity of making and insuring leak-tight fluid connections in orbit. A deployable radiator would simplify initial on-orbit buildup, but at significant system complexity, weight, and cost. The deployment mechanism will be inherently complex, requiring drive motors, fluid swivels, and flex hoses; these would increase radiator weight by 25-50%. Heat-pipe radiators readily lend themselves to on-orbit construction since they are made up of several independent, closed elements. The leak of a single heat pipe during construction would not significantly reduce overall system performance. Construction in space would require on-orbit crew time using the Shuttle's remote manipulator system (RMS), but would decrease overall radiator system complexity, weight, and cost. Perhaps of overriding importance for the life requirements of the space station, space construction would be inherently maintainable on orbit.

A space-constructible radiator that fully meets the challenges could use the large (~2-kW) independent heat-pipe elements and a centralized heat-transport circuit. Any radiator area would be formed by putting together the required number of heat transfer elements.

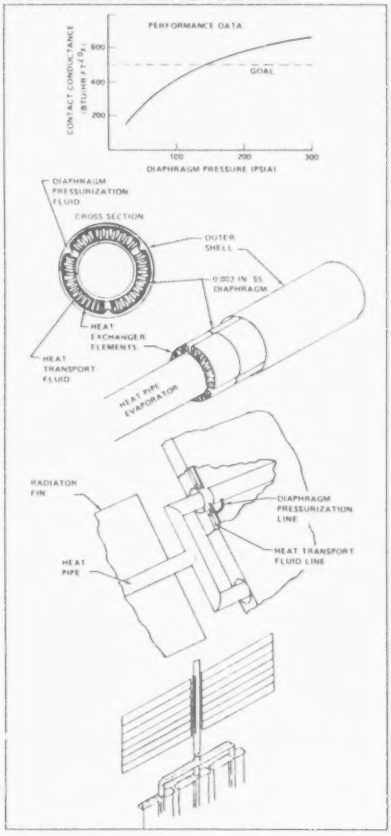
The space-constructible heat-pipe radiator, illustrated in the rendering near the beginning of this article, would reduce the number of radiator elements by an order of magnitude (e.g., 50 heat pipes vs. 1500 fluid tubes for a typical 100-kW system). The reasonable size and relatively small number of radiator elements make RMS use practical. Individual heat-pipe elements could likewise easily be replaced or upgraded. Launch weight and volume would be minimized because the radiator elements could be compactly stowed.

The requirement to transfer up to 100 kW out of the heat-transport circuit and into the radiator system through a *contact* heat exchanger presents one of the major challenges for any type of thermal-management system. Interfaces must be attachable and detachable in a zero-*g* space environment using the RMS. That complicates the design of its elements. Heat transfer must have a low temperature drop. That necessitates intimate thermal contact across the joint. Bolted joints have been used both for ground and space applications, and interface materials such as indium foil and thermal grease have been used to aid heat transfer. But such joints would be very hard to assemble in space.

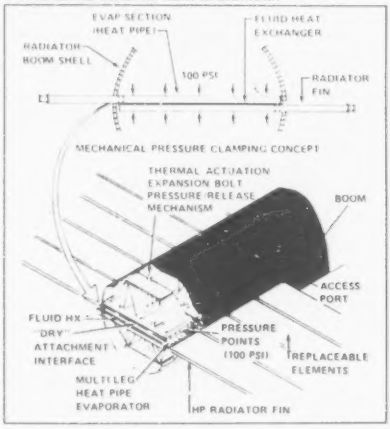
Two types of thermal-contact joints have been investigated as alternatives. Both rely upon the application of pressure to dry surfaces in intimate contact to provide the required heat transfer. In one (F-3) the RMS would insert the evaporator of the heat-pipe panel into the heat exchanger. Gas or hydraulic pressure against a diaphragm would force contact between the surface of the heat pipe and the fluid heat exchanger. Heat-transfer coefficients as high as 500 Btu/hr-ft^2 have been measured for joint pressures of 150 psi (see F-4). The disadvantage of this concept involves the added complexity of components associated with the gas or hydraulic pressurization system.

F-4 illustrates a second approach, using a flat contact heat exchanger. Thermal-expansion bolts and a truss assembly apply 100-psi pressure to the interface to distribute the load over the contact surface. A prototype heat exchanger of this type is be-

F-3 MECHANICAL CONTACT HEAT EXCHANGER

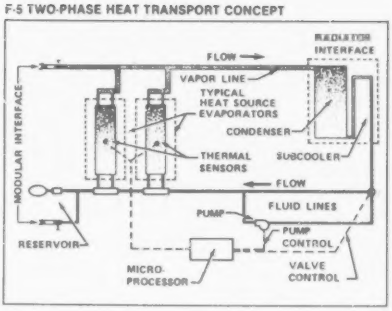


F-4 PRESSURE-CLAMPED HEAT EXCHANGER



38-036 O - 84 - 55

F-5 TWO-PHASE HEAT TRANSPORT CONCEPT



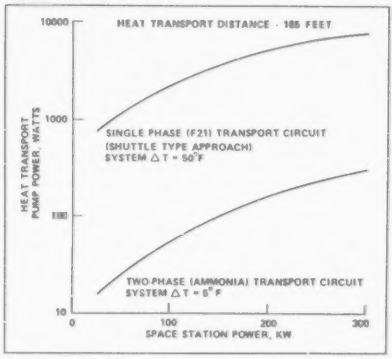
ing fabricated.

In previous manned spacecraft, pumped liquids have transported heat between sources and the radiator heat sink. These conventional loop systems use mechanical pumps to circulate Freon 21 or water. Pumped-loop technology has been found to be fairly reliable. However, when sized for a space station, they bring severe pump-power penalties and operational constraints. Pump-power penalties for a 100-150-kW space station would be on the order of 3-5 kW. This would not only be a very significant energy consumer, but also would require extremely large and costly space-qualified pumps to be developed and fabricated. The large pumps would be major sources of noise and vibration. Furthermore, their periodic maintenance, refurbishment, or replacement would be a continuing drain on operating costs and crew time.

Operational constraints of the pumped-fluid system would reflect the large temperature differentials around the fluid circuit. (The Shuttle Freon 21 loop operates with a temperature differential of about 50 F, from 40 to 90 F, during its path around the heat-transport circuit.) Varying and constantly increasing heat-transport fluid temperature would require equipment to be placed in the circuit at the *precise* place where fluid temperature could handle the necessary cooling. Thus, equipment must either be placed in proper order or fluid lines must often double back on themselves to place equipment in proper order relative to the fluid loop. This is an acceptable burden on small spacecraft and is tolerable even on large spacecraft like the Orbiter, which has fixed heat loads. However, even on the Shuttle, the liquid circuit places undesirable limits on payload thermal support. For a large and evolving space station, needing flexibility in place and magnitude of heat loads, a pumped-liquid system will impose severe operational constraints—perhaps even severe enough to prohibit certain missions.

A space-station system has been conceived to solve such problems—a two-phase heat-transport circuit (F-5) that moves heat into or out of the loop by evaporation or condensation of a working fluid (e.g., ammonia). The prime mover for the fluid is a small pump in the liquid portion of the loop. Evaporative heat exchangers remove the heat load from individual subsystems or payloads. The vapor from the heat exchanger is fed through a vapor-return line to the radiator interface heat exchanger where it is condensed and slightly subcooled. The liquid that comes from the radiator heat exchanger is then circulated back to the heat loads by the pump. Because heat transport is determined by the heat of vaporization (e.g., ammonia, 589 Btu/lb/°F) rather than the heat capacity of Freon 21 (0.24 Btu/lb/°F), the pump flow requirements are at least 50 times less for this system than they would be for a Freon 21 fluid-circulation system. Many of the components, particulary the pump, can thus be much smaller.

F-6 POWER REQUIREMENTS FOR SINGLE- VS. TWO-PHASE HEAT TRANSPORT CIRCUIT



F-6 illustrates the overwhelming advantage in pump power of a two-phase heat transport circuit over a Shuttle-type pumped-liquid circuit: for a 100-150-kW space station, less than 100 W compared to 3-5 kW for a pumped-liquid system. Long-life space-qualified pumps of 100 W or less are readily available.

Because the evaporation and condensation processes are essentially isothermal, the two-phase loop provides a uniform thermal-control bus temperature for space-station subsystems, experimental

equipment, and payloads. It eliminates the need for sequencing of heat-generating equipment. It broadly serves the overall needs of space-station modularity, operational flexibility, and evolutionary growth.

Several two-phase-circuit hardware test programs have proved the feasibility of the thermal-bus concept. A capillary-pumped two-phase loop (CPL), developed in the mid-Sixties, transfers significant quantities of heat with little temperature drop and no external pumping. It consists basically of a wick evaporator and continuous loop. Recently, a new prototype was developed and tested with Freon 11 on a 33-ft-long CPL. It demonstrated a capacity of 400 W (158,000 W-in.). Subsequent tests with ammonia demonstrated a capacity of 1,400 W (554,000 W-in.) with only two evaporators. Because the evaporators are in parallel, much higher capacities can be reasonably projected.

Another thermal-bus concept—a pumped, two-phase series loop—has also been tested. It uses a closed pumped-fluid loop serially interfaced with several evaporators.

An alternative would be a pumped, two-phase parallel circuit, and this also is under experimental investigation. Its evaporator, condenser, and vapor and liquid return-lines can be sized independently to achieve optimum tradeoff between pressure drops, heat-transfer performance, volume, and weight.

One additional approach to the thermal bus should be mentioned—the capillary-pumped plate. Two different capillary plates are being investigated. One relies on wick structure for pumping; the other, on machined grooves in the plate.

Out of these many considerations has come a strong candidate for the thermal management system. Illustrated at the beginning of the article, it optimizes system weight, power consumption, growth capability, operational feasibility, maintainability, and cost. The two major elements of the system are the heat-transport and heat-rejection subsystems. The pumped two-phase thermal bus operates at a near-constant temperature, independent of location in the circuit, for payload and subsystem heating or cooling, while requiring less than a tenth of the electrical power of a comparable single-phase pumped-liquid system. Its space-constructible heat-pipe radiator will allow any size of radiator system to be erected or maintained at any time during the space station's evolution by simply combining the required number of identical, independent heat-pipe radiator modules. The same basic high-capacity heat pipe would be used in a combination meteoroid-shield/radiator module design to minimize deployed radiator area.

SPACE STATION TECHNOLOGY

HUMAN CAPABILITIES

Long Residence an Uncharted Field

By ALAN CHAMBERS
NASA Ames Research Center

Skylab and Soviet space-station work confirmed that man can live and work in space for several months. Both demonstrated man's ability to overcome unexpected difficulties. Without the extravehicular repair of a damaged solar array and placement of a sunshade, the entire Skylab program would have failed.

We have seen the value of the astronaut as pilot, scientific observer, systems manager, and engineering technician. The Shuttle program continues to exploit a crew in these roles.

One can predict, however, that the change from the intermittent flights of the past to permanent residence in space will bring problems. Once in operation, the space station will not be seen as a "one-of-a-kind" space spectacular, and the astronaut will lose the aura of hero or novelty. The extensive training which has characterized earlier programs will diminish under the pressure of increased launch rates. And, as their roles expand, crews operating in space will come from a far more heterogeneous group socially, educationally, physiologically, and psychologically.

Moreover, advanced computer technology with high speed, high-capacity onboard data processing will change the relations of ground and space operators. It will bring about changes in command and control strategy and psychology, requiring careful integration of people and technologies.

Living and working in the space station indeed requires fresh thought, from questions of food to robotics and Extra-Vehicular Activity (EVA).

Shuttle food provisions emphasize high-energy content, dense packaging, and unitary servings for quick access (F-1). Limitations in preservation technology cut out many foods and processes such as

ALAN B. CHAMBERS, chief of the Man-Vehicle Systems Research Div. at NASA-Ames, has worked on the problems of man in space, particularly environmental control, for 15 years. He has served on the Air Force Science Advisory Board since 1960.

freeze drying and reconstitution significantly alter others. But that deficiency will change as people in space press for better, more normal meals. Improved means of preservation, bulk storage, and reconstitution will probably precede even limited onboard production of foodstuffs, but technology to grow food in space will be a long-term goal. Packaging and onboard preparation, including means to reduce waste and prevent spoilage, need near-term improvement. A better food technology should serve the space-station occupants. By and large, it has not been created.

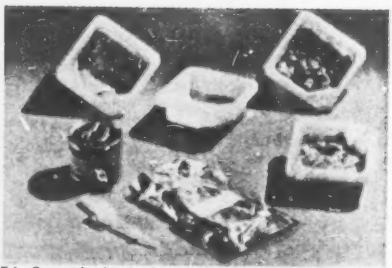
Another concern is contaminants. Space missions involve elaborate precautions to prevent crew exposure to pathogens and equipment-related toxins, vapors, and particulates. New considerations arise with respect to permanently manned vehicles. Periodic rotation of personnel and onboard experiments involving animals and other life, will expose stabilized, susceptible crew members to new pathogens. All manner of equipment and operations (manufacturing, vehicle maneuvering, maintenance and repair, and waste disposal) also will increase exposure to contaminants. Decontamination, containment, and prevention technologies are yet to be developed.

A permanent station will need new, more comprehensive health maintenance procedures and provision for care of sick and injured crew members. Our assessment of medical risk factors indicates that research and technology programs should be started in numerous areas. It is necessary to define differences between the physiologic normal values on Earth and in space, identify effective zero-gravity therapeutic methods, develop medical equipment, test these concepts in space, and establish design criteria for space-station medical facilities.

Several other aspects of the physical environment will affect the long-term habitability of the space station. The vibroacoustic environment, for example, will directly affect the comfort and performance of the crew.

On Earth, much low-frequency noise goes through the "walls" to the outside atmosphere. In space, with the absence of this energy-absorbing atmosphere, the acoustic energy is reflected and may increase the interior background noise by 12 dB or more. Many of the onboard noise sources will be operated periodically, resulting in intermittent sound and vibration that could potentially be more distracting than continuous noise.

F-2 describes measured noise levels of Skylab and Shuttle and predicted levels for Spacelab equipment, along with Earth-based noise criteria. Measured levels have exceeded those acceptable for various activities, and have caused crew complaints, indicating need for better prediction and control. In some cases, adverse reactions to noise have developed despite fulfullment of design specifications. Shuttle and other orbital vehicles should incorporate improved design and control techniques that can be applied to the space station.



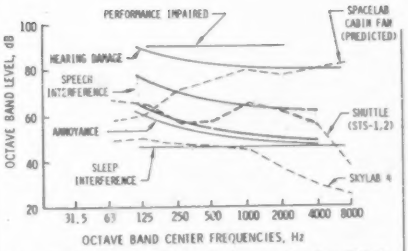
F-1 Current food technology, typified by packaged Space Shuttle fare, needs substantial development before space station crew members can hope for "normal" meals.

Many other habitability issues—architecture, personal hygiene and housekeeping, characteristics of the internal environment, crew work/rest cycles and off-duty activity—remain unresolved. Insights and answers may come from studying upcoming space operations. Although perhaps not concerned with hard technology, they may strongly affect performance in the space station.

As already indicated, two interacting concepts, automation and autonomy, will play an increasingly important role as space-station plans mature. In this context, automation means the degree to which space-station operations require manual control or intervention. Autonomy means the extent to which the space station becomes independent of ground support. A major challenge will be to determine how many ground-based functions can successfully migrate to the space station. Likewise, it should be understood how automation and autonomy affect the long-term performance and well-being of the space-station habitants. The interactions of displays, control, and data management need investigation. Existing specifications must be updated to include state-of-the-art technology and man-machine-oriented design models.

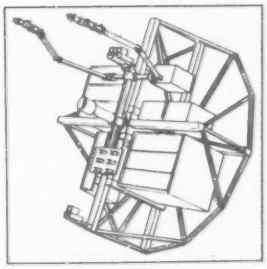
Teleoperators (F-3) no doubt will greatly improve man's overall ability to function in and from the space station. As teleoperator systems become more complex, however, control systems will have to be improved from what we have operating now. This will particularly be true for multi-task, multi-arm, and multi-operator systems. Modeling and simulation must stay abreast of advances in man-machine systems. An integrated program of hardware development, analysis, simulation, and evaluation should pace teleoperator technology readiness.

EVA unknowns compel more research. Several

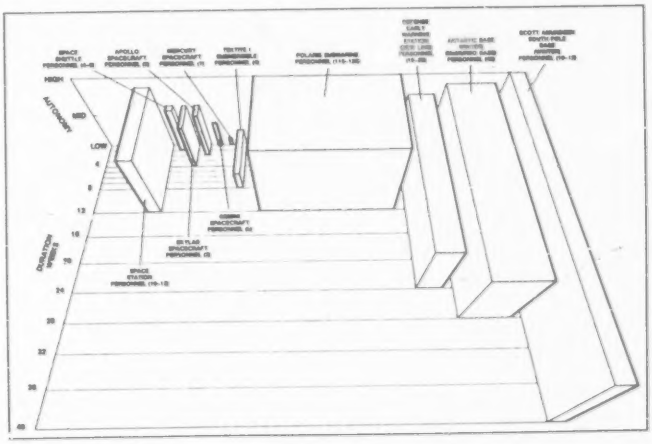


F-2 Space vehicle sound intensity (measured and predicted). "Amplification" of noise in a station in airless space could, unless attenuated, be injurious with long residence.

F-3 Remote orbital servicing system. Teleoperator technology aims at limiting space station's ground dependence.



F-4 Habitability analogs offer helpful guidelines for understanding crew reactions to extended periods of restriction in a space station.



technology development needs can be identified: restraint and attachment systems, communications, and information display to the EVA crew. A family of options must be developed to adequately cover worksite operations.

Other potential EVA requires attention. The duration and complexity of the space-station mission will require maintenance procedures for machine shop, repair shop, or depot. We know little about the effects of massive machinery upon a space-station environment (such as the pollution created by the residues of machine operation). Diagnostic operations, optics cleaning and refurbishing, lubrication and bonding will have to be addressed. Techniques are needed for overcoming the cumbersome space-suit glove. Dexterous tools and manipulators which approximate bare-hand work are needed for effective EVA.

The Shuttle gives us the opportunity to perform experiments that can promote good productivity from people and machines. Shuttle experiments, especially regarding food technology, virbroacoustic environment, EVA, and teleoperators can greatly clarify design decisions for the initial station.

The short missions planned for the Shuttle do not allow examination of all relevant issues, such as onboard management and effects of long-term isolation. On the other hand, we have extensive experience from nuclear submarines and antarctic bases (F-4), and this should help to plan operations and prevent problems.

The presence of a larger, more heterogeneous team in the space station will require technology beyond that necessary on previous missions. In order to meet this challenge, we will begin by taking full advantage of the Space Shuttle and lessons from the development and operation of these other, analogous systems to the space base.

SPACE STATION TECHNOLOGY

PROPULSION AND FLUID MANAGEMENT

Station Keeping Will Eat Energy on a New Scale

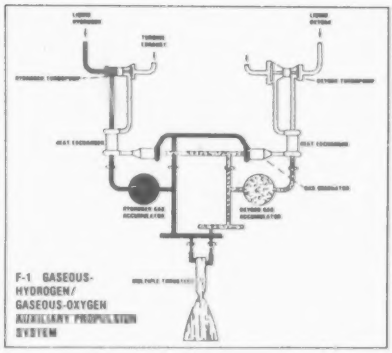
By DONALD A. PETRASH
NASA Lewis Research Center

In examining onboard propulsion and reduced-gravity fluid management, emphasis has been placed on identifying technologies that could be brought to a state of minimal development risk in the near term yet offer the potential for evolutionary growth consistent with future space-station propulsion requirements. We have reviewed needs for safety, integration of systems, and maintenance. The probable propellants for auxiliary propulsion are used in other systems and thus offer a resupply benefit and a benign rather than corrosive or toxic handling environment.

Auxiliary Propulsion: The auxiliary propulsion system provides attitude control, orbit change, acceleration control, and controlled de-orbit. The wide range of thrust required led to a mixed high/low propulsion system using chemical engines for all high-thrust applications and electrical engines for all low-thrust applications.

Considered state-of-the-art were the storable monopropellant and bipropellant pressure-fed propulsion systems now in use. Near-term technologies include a gaseous-oxygen/gaseous-hydrogen propulsion system, a resistojet, and improved diagnostics for both. Long-term technologies include inert-gas ion propulsion and electrothermal propulsion. Placed in a future (post-1990s) group and dropped from consideration, because they would require too much development, were solar thermal, nuclear, and arcjet rockets.

The anticipated total energy requirement for station keeping of large platforms in low Earth orbit (LEO) greatly exceeds the moderate requirements of present spacecraft. Higher specific impulse, moderate thrust, and high performance become increasingly important. A gaseous hydrogen/oxygen system will satisfy these requirements. As conceived, the system (F-1) draws liquid oxygen and liquid hydrogen from storage tanks, pumps them to the required system pressure, vaporizes the liquids, and stores the gaseous propellants in accumulators for feeding to the thrusters. A gas generator supplies the hot-gas working fluid for the propellant vaporizer and turbine drive of the pump. Overall performance will depend on the selected thrust level and propellant conditioning system; but specific impulse should fall between 375 and 400 sec. This system has a mature technology base.



F-1 GASEOUS-HYDROGEN/GASEOUS-OXYGEN AUXILIARY PROPULSION SYSTEM

The resistojet, an electrothermal device, uses a resistively heated energy exchanger to heat a gaseous propellant and then expand it through a nozzle. It requires externally produced electrical power. Thrust is low—about 0.2 N of thrust per kilowatt. Depending on propellant selection, specific impulse can range from 300 to 600 sec using near-term, low-risk technology. It can range up to 1000 sec with advanced technology. The resistojet can use various propellants, including storables such as hydrazine and ammonia, hydrogen, and those commonly associated with manned systems—water, carbon dioxide, and methane. The effluents in most cases are like the propellants, nonreactive and noncontaminating. Long-term ground and space tests have built a good data base on resistojets. (An operational communications satellite uses hydrazine resistojets.) Technology advances appear to entail very low risk and offer a high growth potential.

The need for both ground and on-orbit inspection and monitoring for useful life will require better engine diagnostics. The diagnostics must permit timely, cost-effective repair or replacement of

DONALD A. PETRASH, as chief of the Space Propulsion Div. at NASA-Lewis, heads research on H_2/O_2 upper stage and electric propulsion, for which Lewis is NASA's lead center. Earlier, he directed work on reducing aircraft engine emissions.

system components. The precise diagnostic requirements have yet to be determined, but they will call for technology development of sensors.

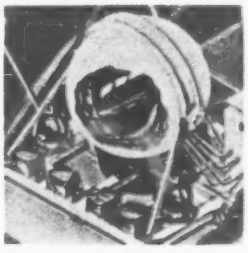
Inert-gas ion thrusters offer the highest performance of the proposed propulsion concepts. Through high performance, low thrust, and benign effluents, these engines offer cost, performance, and integration benefits for large space systems in high Earth orbits and free flyers associated with a LEO space station. High specific impulse means less mass and longer system life; that spells less spacecraft maintenance and resupply costs.

Fluid Management: The space station will store and supply a variety of fluids, including cryogens and refrigerants, to meet the needs of various subsystems. In the near term, fluid management will be dictated by the needs of the station's own operational subsystems. In the far term, it will probably be dominated by the desire to refuel space-based Orbit Transfer Vehicles (OTVs). As the station evolves, experiments, satellites, and OTV payloads may rely on it for periodic servicing and resupply of fluids.

Obviously, fluid-management subsystem requirements and characteristics cannot be fully defined until a reasonably firm mission scenario has been established and other space-station subsystems have been defined more clearly. It is possible, however, to see major options. A few questions bring them into focus.

Will a centralized storage and supply system be possible, or are the fluid requirements too diverse? Should resupply be by individual tank replacement, a logistics-module exchange, or transfer from a tanker via interconnecting lines? Where will the fluids come from?

Centralized fluid storage and supply that allows integration of space-station systems appears attractive if the variety of required fluids can be kept small. Adoption of centralized fluid management will simplify logistics. It will give the maximum fluid margin to meet contingencies—for instance, OTV propellants could be used in a fuel cell to provide emergency electrical power. Use of common fluids meeting the requirements of several systems adequately must be compared with the choice of a fluid to meet each system's requirements optimally. This will be the subject of much further study.



F-2 Experimental cryogenic fluid transfer unit would recover unused Shuttle propellants to fuel OTV.

For relatively small fluid quantities, the designer must consider the periodic replacement of individual fluid tanks and use of a logistics module for the complete fluid storage and supply subsystem. As the space station grows, it will be necessary to transfer fluids from the Shuttle Orbiter to the station, preferably by interconnecting lines. Fluid-replenishment options need to be compared on the basis of operational complexity, Earth-to-orbit transportation costs, availability of technology, and impact on evolution of the space station.

Liquid hydrogen and liquid oxygen will eventually be stored on the space station to support OTV operation. Options for making these fluids available need to be explored. Methods of recovering unused propellants from the Shuttle Orbiter and External Tank need evaluation to define Shuttle modifications and performance penalties. It will be necessary to compare the economics of dedicated Shuttle fluid-resupply missions, manifesting of Shuttle payloads to provide maximum use of Shuttle capability by using fluid tanks of different size, weight, and geometry, and the Earth-to-orbit transportation of water and hydrazine followed by on-orbit manufacture of propellants by electrolysis or catalytic reaction and liquefaction.

NASA has programs to develop the ability to store and supply cryogenic liquids on orbit and to resupply both noncryogenic and cryogenic liquid systems by liquid transfer from the Shuttle. F-2 depicts an experimental liquid-hydrogen transfer unit mounted on a Shuttle/Spacelab pallet. It will be used to establish operational techniques and design criteria.

We also see a need to develop—

—Leak-proof fluid couplings and leak-detection techniques to enable safe and contamination-free fluid interconnections and transfer.

—Fluid-quantity gauges that give accurate readings under weightlessness.

—Reusable and lightweight insulation for Shuttle tankage used to transport cryogenic liquids.

—Long-term orbital cryogenic-liquid storage facilities, possibly employing refrigeration and liquefaction systems.

In summary, several options for space-station auxiliary propulsion come within the state of the art, yet have growth potential demanded by the evolutionary nature of the project.

NASA has broad research and technology programs, including industry and university expertise and test facilities to produce and system test engineering-model hardware.

SPACE STATION TECHNOLOGY

STRUCTURES AND MECHANISMS

Streamlining for Fuel Economy

By MICHAEL F. CARD
NASA Langley Research Center

Being evolutionary, a space station will pose new problems in structural design. To make transportation costs as low as possible, station structure must be packaged efficiently in high-density modules taking the minimum of Shuttle volume fractions. Once in orbit, these elements must be deployed and assembled with a high degree of reliability. The inherent mechanical complexity of deployable structures must be traded against risking man in less complex erection activities. NASA and industrial R&D has shown the practicality of a crew erecting space structures (F-1).

In terms of architecture, a master plan must be created which exploits near-term hardware, yet can grow into a large complex. Basic issue: how to build into components the means for structural growth without compromising the initial system. F-2 depicts one possible solution—an initial configuration becoming part of a stiff closed cell in the final configuration. A stiff configuration is expected to reduce control-system problems.

How much should be invested initially to permit configuration growth? In terms of structural design, growth can be achieved by increasing initial design safety factors, introducing dynamic isolators to prevent loads from reaching the initial components, or preplanning refurbishment of initial structure with stronger elements. Intelligent design tradeoffs require definition of on-orbit loads (including docking and maneuvering) translated into load spectra for estimating fatigue life.

Structural components of the station will likely include tanks for long-duration fuel storage, manned capsules, large (possibly inflatable space-hardened) hangars, and large solar-array appendages. This ensemble will be drag-prone. Indeed, drag in low Earth orbit makes configuration a key parameter in system tradeoffs. F-3 gives estimates of Shuttle fuel deliveries required to keep large solar arrays or platforms in orbit for 20 years (Kyser, NASA 16620). A 150-kW Sun-pointing solar array in a 220-n.mi. orbit requires over 120,000 lb of fuel for 20-year life *without drag reduction*. A Sun-pointing array trimmed to a trailing attitude in shadow needs a lesser amount of fuel—something over 85,000 lb. A fixed trailing array (about twice the size of a Sun-pointing array) can cut fuel requirements to about one-fifth (26,000 lb) of the requirement for the untrimmed Sun-pointing array. The desire to reduce drag could make cable stiffening attractive.

MICHAEL F. CARD (AF), as chief of the Structures and Dynamics Division at NASA-Langley, oversees research on structural dynamics, solid mechanics, failure analysis, and composites. Card formerly chaired the AIAA Structures Technical Committee.

Structural joint's sockets slip together, then lock. F-1 shows joints being fitted into a space structure.

Because of the evolutionary nature of the space station, an archive of engineering design data will be needed to track configurations. F-4 suggests an integrated scheme for data bases, optimization analysis, and checking by critical tests. Data bases would be alterable at the analyst's or designer's convenience after stringent verification of proposed new data. The data base would be transferable to different computer operating systems, thus avoiding the need to convert computational codes.

Since full-scale "mated" static and dynamic tests will not be feasible as the station grows, designers will have to rely on analysis for qualification of

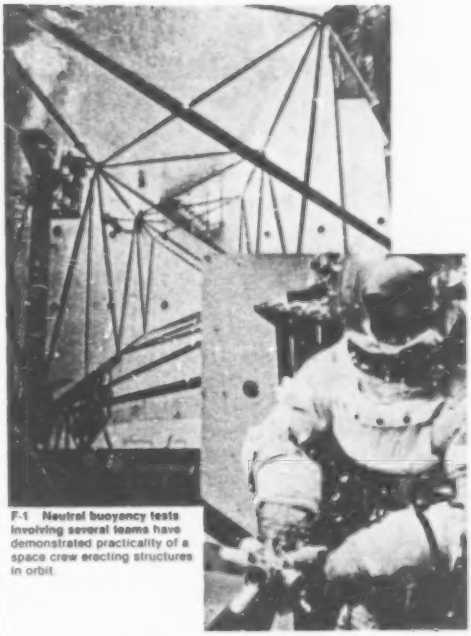
structures. F-5 describes an approach for obtaining a mathematical model that builds on pathfinder and structural models. Space-station complexity will pose a need for improvements in thermal, structural, and controls analyses—model simplifications, reduced computation times for heat-transfer calculations, methods of handling structural nonlinearities, (e.g., in solar arrays and articulated mechanisms), and improvements in modal synthesis and system identification.

F-5 shows need for four activities. A pathfinder model will be needed as soon as the basic configuration is known; it will be used to identify and resolve test and fundamental analysis issues. A replica-model program parallels full-scale hardware development. Unlike past programs, this model would continue as long as the space station grows. It will be the only source of mated vibration test data before orbital assembly. In parallel with this replica program component and element full-scale testing would be done. Finally, on-orbit vibration tests would check ground-test data and analyses and measure characteristics to be entered into the archival data base.

The long-life requirements of a space station will produce unique problems. Improvements in materials must be made to reduce contamination, slow materials degradation, and extend the life of coatings. F-6 describes a typical material degradation—change in solar absorptance of paints and reflective surfaces after several years exposure on a spacecraft in polar orbit (Winn, AFML-TR-78-79). Paints show continuous degradation whereas secondary reflective surfaces appear to stabilize after initial degradation (probably due to early contamination). More data on degradation is needed to characterize a broader range of materials, particulary composites. If deterioration cannot be prevented, simple methods of repair must be devised to restore desirable qualities.

The long-term integrity of structures must be preserved. Structures will need localized protection of critical elements against space debris and micrometeoroids. Redundant, fail-safe structures are likely to be employed with some form of on-board fault detection, especially for tankage. We may need to apply small forces to observe changes in characteristic "signatures" of on-orbit structures to test their integrity.

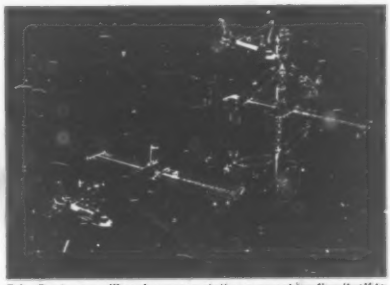
To minimize on-orbit maintenance, long-life lubrication systems and advanced sealing concepts must be developed. Solid-film lubricants and self-acting seals developed for engine applications need further research to determine their long-time integrity in applications such as docking latches and



F-1 Neutral buoyancy tests involving several teams have demonstrated practicality of a space crew erecting structures in orbit.

cryogenic pumps. Advances must be made in the reliability of mechanisms to avoid costly errors in detail design. Computer-aided kinematic analysis of real mechanical systems (including effects of tolerances, interference and flexibility) should improve design quality.

The spectacular growth of microprocessor technology suggests the development of "smart" mechanisms—programmable mechanisms having sensor feedback and capable of performing multiple functions, such as the "next generation" space-crane



F-2 Designers will seek a space-station concept lending itself to evolution. Sketch indicates one approach—an initial, relatively simple power-cell platform becoming part of a stiff closed cell.

F-3 FUEL REQUIRED TO MAINTAIN A 20-YR ORBIT

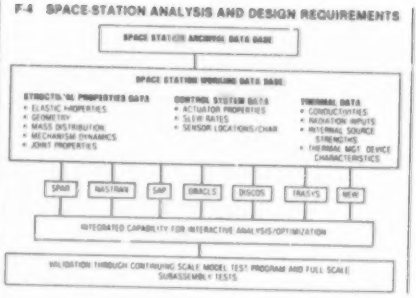
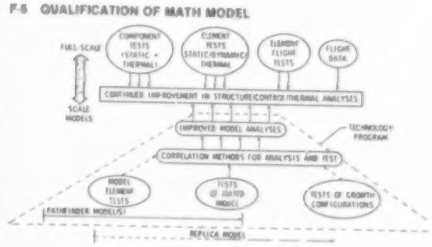
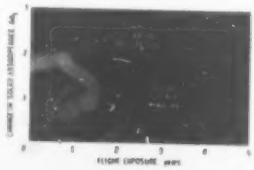
F-4 SPACE STATION ANALYSIS AND DESIGN REQUIREMENTS



F-5 QUALIFICATION OF MATH MODEL



F-6 DEGRADATION OF THERMAL-CONTROL COATINGS
Flight data from AFML-TR-78-99.



F-7 "Next-generation" space crane, along these lines, would use local sensors and actuators under programmed master control to take any desired configuration.

concept illustrated in F-7. Through a combination of local actuators and sensors, it can be programmed to retract and deploy and take a position in any desired configuration. Designers will likewise need reliable moving joints and latches with minimum deadband, low coefficient of expansion, long life, and high functional reliability.

To complement this development, a family of fluid couplings and electrical connectors needs to be developed and integrated with mechanical subsystems for module hookups, satellite maintenance, and refueling operations.

Finally, we will need new mechanisms for docking. Concepts are being investigated to reduce docking loads ("soft" docking with final velocities less than 0.1 ft/sec) and to berth inert payloads.

Technical concerns and a desire to develop experience in space station operations will likely lead to early experiments using the Shuttle. One logical candidate for a pathfinder experiment will be space construction. Problems in the dynamics and control of large flexible structures should also lead to pre-station flight experiments; basic issues are ability to predict and control vibrations on orbit, and to perform vibration testing, practical systems for orbit control, and usefulness of adaptive control.

NASA is studying practical approaches for performing low-cost experiments. A reusable pallet, called the Space Technology Experiments Pallet, would minimize integration cost and would allow reuse of expensive electronics. Plans so far would have the pallet used specifically for structures, structural-dynamic, and controls experiments that can be packaged compactly to allow convenient payload manifesting.

The development of a space station requires creative structural engineering to evolve a simple power module into a complex permanent base. The viability of this "infinite life" spacecraft will reflect the ingenuity of materials and structures engineers in solving durability and maintenance problems. ☐

SPACE CITY

2001 it's not.

by M. Mitchell Waldrop

Illustrations by Ron Miller

In 1869 the Atlantic Monthly published a whimsical and charming serial called The Brick Moon by the Boston clergyman Edward Everett Hale. Hale's creation was a utilitarian satellite made of brick that being visible from Earth, helped sailors navigate the seas. Its 37 occupants communicated with the ground by hopping in unison on the exterior of the satellite in Morse code. It was the first space station in science fiction.

Almost 100 years later there appeared the most famous space station in science fiction--the giant, rotating wheel in the film 2001. This one was a lot more plausible; the movie even featured a visit to the station by a winged shuttle craft.

The irony, however, is that for the last two years or

so the National Aeronautics and Space Administration has been hard at work planning a *real* space station, and its plans are turning out to be a good deal closer in spirit to Hale's utilitarian mass of brick than to the more glamorous wheel. The political realities of the 1980s make it clear there will be no return to the glory days of the Apollo moon landings when space spectaculars were their own justification. If NASA wants a multibillion-dollar space station, and it's hard to see how the cost could be less, then the country had better get a few billion dollars' worth of use out of it.

NASA's station would not even resemble a wheel. In fact, since it will have to be pieced together out of modules ferried up one at a time by the space shuttle, it will look more like something a child would build with an Erector set. The station probably would not rotate; the astronauts' experience with Apollo and Skylab showed that centrifugal imitations of gravity are unnecessary. Nor would it soar very high; the shuttle is limited to orbits under 700 miles. But it would be a permanent base for humans in space, something that space pioneers and science fiction writers have dreamed of for generations.

In the course of planning the space station, NASA has asked scientists, businessmen, and other prospective tenants precisely how such a station might help them do their jobs. The question initially surprised a lot of people who were still getting used to the space shuttle. But once they had thought about it, they all had very definite ideas of what they would need.

In astronomy, for example, some of the most exciting advances in the last decade have come from orbiting instruments sensitive to X rays, gamma rays, ultraviolet light, and infrared light, all wavelengths of the electromagnetic spectrum that are screened out by Earth's atmosphere. With their detectors placed beyond this screen, astronomers have seen pulsars, supernovae, stars in the process of being born, and even, apparently, black holes. They are hungry to see more. With the space telescope, scheduled to be launched above the murk of Earth's atmosphere in 1986, they will be able to observe the planets in exquisite detail and study how faint, distant galaxies began forming in the aftermath of the Big Bang. Even more advanced instruments are being designed, some of which may be able to peer into the hearts of far-distant quasars and explain the source of their immense power.

These new telescopes could be flown on the shuttle or placed on separate satellites. But a panel of astronomers who recently studied the question for the National Academy of Sciences agreed that it would probably be more efficient to assemble many instruments on a single space platform where they could stay up indefinitely and share power, tracking, and communications hardware. The researchers stressed, however, that it should be an unmanned platform. They don't want their high-resolution telescopes shuddering every time somebody goes from the kitchen to the bathroom. On the other hand, the astronomers do want people nearby so they can visit regularly to change or repair equipment and replenish the liquid helium used to cool detectors.

Meanwhile, the people who work on exotic materials want just the opposite, a manned laboratory where they can run experiments in person in a comfortable, shirt-sleeves environment. The lab will not be glamorous: It will look like a tin can outside; inside it will resemble an airliner with its ceiling and walls covered with electronics and apparatus. But the lab will be serviceable, for space offers access to round-the-clock solar power and, more important, microgravity—*micro* instead of *zero* because there will always be a little bit of acceleration from atmospheric drag and any bumps and bangs that might shake the station.

Many enthusiasts have held out the promise of whole new industries in space. A weightless liquid, for example, need never touch the walls of its container, so researchers may be able to cool molten blobs of ultrapure silicon into semiconductor crystals in space without ever having to worry about contamination from the container. Nor is a weightless liquid roiled by convection currents, since there is little gravity to make the warmer

layers rise and the cooler ones fall. Thus, it may be possible to grow crystals that are larger and more perfect than any on Earth. By the same token scientists in space may be able to make new kinds of alloys from metals that separate like oil and water on Earth.

When the shuttle carries the European Space Agency's *Spacelab* aloft for its first flight this fall, at least half of its 77 experiments will be of that kind. "We're really looking forward to the station so we can get a lot of work done instead of one shot at a time," says Lowell K. Zoller, manager of the Engineering and Major Tests office at NASA's Marshall Space Flight Center in Huntsville, Alabama.

Spacelab, a joint venture of the European Space Agency and NASA, is scheduled to fly on the shuttle this fall. One American and one European scientist will conduct more than 70 experiments designed to answer such questions as how the sun affects Earth's weather and how plants know which way is up. Telescopes and sensors, on the pallet behind the lab, will be open to space.

In a separate endeavor, the aerospace company McDonnell-Douglas has teamed up with the Ortho Pharmaceutical Corporation, a subsidiary of Johnson & Johnson, to test a microgravity process for separating biological substances such as interferon and insulin-secreting beta cells. The process is an adaptation of a well-known laboratory technique called electrophoresis in which materials are suspended in a liquid and separated by an electric field. Without convection currents, the separation process in space is hundreds of times more efficient than it is on Earth. The partners have successfully tested their process and are now building a prototype manufacturing plant. The fully automated plant could be aboard the shuttle as soon as 1985. But they look to the space station for a full-time factory.

Ever since the space communications industry began booming in the 1960s, the trend has been to put more and bigger antennas on big-

(continued on page 66)

Evolution of the space station

Edward Everett Hale, best known as the author of the American classic *The Man Without a Country*, described the first manned space station in 1869 in a funny and fanciful short novel entitled *The Brick Moon*. Hale detailed plans to launch a globe-circling, 200-foot sphere that would serve as an aid to navigators at sea. His brick moon, supported by 13 internal spheres, was coated with a ceramic powder that would fuse as it flew through the atmosphere to provide a heat-resistant shell very similar to the ceramic nose cones and heat shields of today's spacecraft. Accidentally launched with 37 people and food and water aboard, the moon reached an altitude of 4,000 miles. Favored with gravity, an atmosphere, and abundant rainfall for their crops—Hale doesn't explain how that was possible—the inhabitants thrived and multiplied, as shown at bottom left in the illustration above. They even witnessed evolution of a sort. "Write to Darwin," they signaled to Earth, "that he is all right. We began with lichens and have come as far as palms and hemlocks."

Hermann Oberth, the German rocket pioneer, proposed a much more likely but much less charming scenario in his 1923 book, *The Rocket into Interplanetary Space*. Like a great many who followed him, Oberth overestimated the need for gravity. To create it, he proposed two manned rockets of about 400 tons each, as shown at top left in the painting above. Tethered together by a strong cable a few miles long, the rockets would rotate about each other creating an artificial gravity (an idea revived by NASA in the 1960s for a manned mission to Mars). Oberth also planned an enormous mirror to beam solar energy to Earth.

The first careful scientific description of a space station, which appeared in Hugo Gernsback's magazine *Science Wonder Stories* in 1929, was by an Austrian writing under the pseudonym of Hermann Noordung. Noordung detailed a station consisting of three separate spacecraft: a manned wheel, a solar power plant, and an observatory, all connected by air and power umbilical lines. The main unit was a torus 164 feet in diameter that spun on its axis to provide gravity.

In the late 1940s engineer H. E. Ross and artist engineer R. A. Smith of the British Interplanetary Society described an orbital base serviced by winged cargo rockets that would be a way station for a moon landing. The station would have a 200-foot solar reflector to generate power and a long boom to house radio transmitting apparatus.

The space station conceived by writer Fletcher Pratt and artist Jack Coggins in 1952 was a rare nonspinning, zero-gravity concept. They felt, rightly as it turned out, that gravity might not be a necessity in space, so they designed a station in the form of a hexagonal prism. Winged shuttles would ferry supplies from Earth needed to construct a small, multi-legged ship that would send explorers to the moon.

Probably the most esthetically pleasing and elegant of all space station designs was that of the great German rocket pioneer Wernher von Braun. Developed as part of a symposium on space exploration sponsored by the old *Collier's* magazine in the early 1950s, the design used only available technology and materials. the plan actually would have worked. The station, with its crew of 80 orbiting 1,075 miles above the Earth, was to be attended by a three-stage shuttle. A telescope would orbit nearby. The design was so influential that only recently did the United States and the Soviet Union abandon wheel-shaped stations. The idea survives today in the futuristic space colonies envisioned by Princeton physicist Gerard O'Neill.

With the possible exception of the Pratt-Coggins station, none of these pioneers anticipated what a *real* space station would look like. But that is a small point. For they were convinced of the need for one—and for the varied functions it could fulfill.

—Ron Miller

The first space station could be in orbit by the early 1990s.

(continued from page 63)
ger, more sophisticated satellites. The shuttle will be able to launch the larger antennae planned for the next decade or so, but eventually the satellites may outgrow the shuttle's payload bay. What the industry will need then is a transportation hub: a space station in low Earth orbit tethered to a separate platform with manipulator arms and other gear for assembling several payloads into "antenna farms." The hub would also offer refueling and docking facilities for an unmanned, reusable vehicle that would ferry the antennae up and back to the 22,300-mile geosynchronous orbit, where they will stay fixed over one spot on the equator.

This same transportation hub might also prove useful to planetary science. Researchers have had a decade of extraordinary successes, including the Viking Mars landers in 1976 and the later Voyager flybys of Jupiter and Saturn—followed by a more recent period of severe budgetary constraints. Things are looking up, however, and plans are now afoot to mount follow-up missions in the coming decade to the planets and to the comets and asteroids. If the scientists had access to orbiting facilities for assembly and refueling, they might also be able to mount much more complex missions—collecting and bringing back rock and soil samples from Mars, for example, or sending manned expeditions to nearby asteroids.

The orbiting transportation hub would also be essential for undertaking some of the ambitious projects proposed for the next century—satellites for beaming solar power to Earth, mining colonies on the moon and the asteroids, and eventually, perhaps, vast space colonies with farms, factories, and subdivisions housing tens of thousands of inhabitants.

The group that appears most reticent about the space station is the one that people tend to think would be first in line: the military. President Reagan's call for a space-based *Star Wars* missile defense system last spring only heightened the public's concern about the militarization of space. But even if someone could figure out how to build, say, a particle beam weapon or an X-ray laser—and many physicists have voiced severe doubts on that score—the Pentagon could hardly base them on a space station. Not only would the station be vulnerable to attack, but there would have to be dozens of such weapons in orbit in order to cover the Soviet launch sites around the clock.

The job of reconciling the varied requirements for a permanent base in space falls to John Hodge, an affable, silver-haired, English-born engineer who heads the space station task force at NASA headquarters. "What we're really talking about is a *system*," he says. "We'll have the space shuttle to get from the ground to low Earth orbit, a station in orbit, and a transport from the station to geosynchronous orbit." Because the users' demands are contradictory, he adds, "the buzz word these days is 'distributed architecture'"—NASA argot for a space station that is spread out like a swarm of bees.

The central complex of the swarm would contain a housing module for a rotating crew of four to 12 who would probably stay up for about three months at a time. The command module would contain basic life-support systems and communications gear. Nearby, floating free or tied to the central complex by Kevlar tethers, would be unmanned platforms for astronomy, Earth observation, and materials science. They would be serviced by astronauts or remotely piloted vehicles based at the central complex. Eventually, Hodge says, there might be two such clusters, one in equatorial orbit and one in polar orbit.

Hodge estimates that the system could cost from $7 billion to $9 billion but spaced out over many years. A space station does have one great advantage over a project like the Apollo moon landings or the space shuttle, he points out: It is modular. It can be built a piece at a time, which means that careful planning can keep the yearly cost down to something reasonable. If things move along at the rate that NASA would like, the first modules could be in orbit by the early 1990s.

First, however, NASA has to convince a very skeptical Washington. The budgetary climate these days is not conducive to building a multibillion-dollar space city. And worse, the agency is still trying to live down its image as a bunch of overly enthusiastic space cadets. The reputation is not entirely undeserved. In the late 1960s, as NASA's leaders were trying to fire people's imaginations for a dramatic new commitment in the post-Apollo era, they pushed hard for a gigantic orbital wheel housing 50 or 100 people full-time—the concept depicted in *2001*. The problem was no one could really explain what they wanted it for. Their naiveté fed a growing perception that space was just a stunt. We spent tens of billions of dollars on space Olympics to beat the Russians to the moon, and what were we getting out of it but moon rocks?

In the end, NASA got grudging permission from the Nixon administration to build one small piece of its vision: a reusable "logistics support vehicle" originally intended for ferrying cargo up to the space station and back. We know it now as the space shuttle.

The shuttle, unfortunately, turned out to be far more complex than NASA had imagined. Years of delays and cost overruns hurt the agency's credibility even more.

Thus when NASA administrator James M. Beggs revived the space station idea in 1981, the initial reaction—from some quarters at least—was scathing. "I am concerned that [the space station] will proceed regardless of the real need for such a program because NASA needs it more than the country needs it!" said Wisconsin's Senator William Proxmire.

Even the less vociferous critics wonder if the agency is obsessed with having a "manned" space station for its own sake. No one has any problems with NASA building unmanned platforms for astronomy and such. But what would the astronauts do up there that would justify the cost of maintaining them permanently? Presidential science advisor George A. Keyworth points out that we already have a kind of mobile space station—the European Space Agency's *Spacelab*, designed to ride in the shuttle payload bay like a camper in a pickup truck. "First let's capitalize on the investment we've already made," he says.

Under Beggs, however, NASA has been trying hard to own up to its previous mistakes and to build a solid base of support for the space station. Hodge, for one, is adamant about finding out what the users need before letting the engineers charge ahead with hardware designs. "To hell with the configurations. What are the requirements for the next 25 years?" he asks. He also argues that humans are needed in space—but not for the sake of glory. "Everybody agrees we should have a man in the loop somewhere. The question is whether to leave him on the ground operating things remotely or put him in space." He points out that the cost of maintaining people in space has to be balanced against the potentially high cost of building very smart, very reliable satellites and transmitting prodigious amounts of data up and down.

As for using the shuttle as a mobile space station, he says, it *sounds* good, but the shuttle was not built for that. It is limited in size and can only stay up for seven days. "It would be like trying to turn a truck into a hotel or a factory," he says.

Hodge's boss, NASA Associate Deputy Administrator Phillip E. Culbertson, worries about a failure of the imagination. "People's thinking is conditioned by what they know," he says. "Ask them what their needs are, and they usually describe what they already have. If you had tried to justify the development of television, the automobile, the computer, or the airplane on the basis of somebody's need at the time, you never would have built any of them. So those of us who work in high technology have to have faith that it will pay off."

Does that mean NASA should have a license to do anything it pleases? Hardly. NASA first has to demonstrate that the space station is more than a toy—that it has real utility now and that it opens new possibilities for the future. And in fairness the agency has gone a long way toward doing that.

But it does mean that there is no way to settle the question by analysis and study alone; NASA must persuade the political system, and especially the President, to take that leap of faith. Ronald Reagan is enthusiastic about space. But budgets are very tight. He will be making a decision on the station this fall. If he says yes, NASA will go ahead, and the first components of a space station could be in orbit by 1990 or 1991. If he says no, then the project will be effectively dead in this administration.

If it comes, says Hodge, the space station will be a utilitarian, workaday thing. No space Olympics here. By the very linkage of the words *space* and *utilitarian*, however, the station could prove far more important than all the heroics of Apollo. "Somebody once asked me how I defined success in this business," Hodge says. "And I said, 'Success is the day we have a mission and it doesn't appear in the newspapers.'" S

I. INTRODUCTION

The attributes of the proposed space station program are specifically oriented toward research activities. On the other hand, the ultimate goal of research is to develop technologies which can generate long term benefits for mankind. In our society, unless such technologies are deemed of national interest and thus are government funded, they must stand on their own in the marketplace. Therefore, the objectives of a United States space station should be based on "commercial" criteria; otherwise, such a project will not attract long term funding. The reality of this conclusion should be evident in these times when budgets will continue to be affected by lingering deficits.

At this point, there is encouraging evidence that some potential space station activities could be generating revenues from shuttle related projects within the decade. Specifically, the McDonnell Douglas and Johnson & Johnson electrophoresis prototype pharmaceutical processing experiments show significant promise. Other materials processing concepts as well as remote sensing, as documented by Terra-Mar's analysis for the TRW space station study, indicate substantial potential. Furthermore, the economics and thus the commercial feasibility of such projects will be improved by the operating efficiencies available with an ongoing space station program.

Thus, by the end of the decade, there may be several applications which will seek the services provided by or associated with a space station. That possibility can and should dictate the direction of current space station development. A future space station can generate a substantial proportion of its own funding on the basis of its commercial potential. This potential must be defined and documented in a format that will be well received by the investment community. In addition, each component of space station activity which has commercial potential must be matched with the appropriate financial vehicle available from the investment community. Wall Street is not a monolithic source of capital, and NASA must do its homework to appreciate the opportunities for private financing that a sophisticated investment banker, broker, or institution can provide.

This study will investigate the alternative methods available to NASA to finance the commercial component of its proposed space station. This analysis will be done in the context of Terra-Mar's previous research into the markets for remote sensing data and services and the financing concepts available for funding the next generation of orbiting remote sensing devices.

II. BACKGROUND

The space station as it is presently conceived may be quite different from its ultimate configuration in space. However, one thing is certain -- the space station will be an expensive undertaking. If NASA utilizes government financing (in other words, tax dollars), funding will be accomplished through the normal negotiations that are associated with obtaining money from Congress. On the other hand, if the space program takes on a commercial orientation, then it will be necessary to approach sources of private capital with a reasonable knowledge of their operating procedures and mechanisms. The latter are considerably different from those associated with Congressional funding.

The following analysis will describe in lay terms the process and procedures utilized by the investment community in funding desirable commercial enterprises. However, it should be recognized that investors are guided by one fundamental principle. They would like to get their money back in a reasonable amount of time with some compensation for the risks incurred and/or they would like to see sufficient growth in the fruits of their investment so they will continue to be secure in the knowledge that their dollars are well placed. Furthermore, they would like to see managers using their funds in an efficient and "lean" operation. Investors are generally extremely sensitive to time delays or deviations from proposed budgets. Although there may be some titillation and indeed ego fulfillment associated with seeing one's investment floating in orbit, when it comes down to making decisions, the "bottom line" will almost always be the dominant factor. In this situation, NASA will be given no more or less consideration than a bright-eyed entrepreneur walking in off the street with a new idea. In fact, considering that the entire pool of venture capital within the United States is approximately $5 billion, even enthusiastic pronouncements regarding the benefits of a $10 billion space station may not be well received by the investment community.

Given this situation, NASA will have to learn the language and procedures of the financial services community and perhaps assume a little humility along the way. The space station will be composed of many elements, some of which may fall into the commercial category and may be financed from private sources. However, as with Congress, it will be necessary for NASA officials to approach sources of capital knowing full well the requirements and the correct protocol. An awareness of the psychological as well as financial aspects of raising capital will be necessary.

III. ELEMENTS OF RISK: TECHNOLOGICAL, FINANCIAL, AND POLITICAL UNCERTAINTIES

The financial community has some basic guidelines by which it evaluates all potential investments. The perpetual question is -- what are the risks involved in financing the project? These risks could take the form of technical, financial, or political uncertainties. First, as far as a space station type investment is concerned, technical risks would be those associated with the operation of the facility as specified or as required to generate revenues.

Second, financial risks would be those associated with the required funding and revenues of the project in question. In other words, can the device be built within budget and on schedule and will it generate the projected revenues over its lifetime?

The third element of risk is in the political domain but indirectly relates to the first two elements. Specifically, will a government sponsored space station continue to maintain its priority in the government budget cycle through changes in administration and congressional constituencies? Therefore, if I am an investor in this project that depends on a government supported system, I want to know if I risk finding that space station turned off someday due to lack of interest or due to changes in priority among political constituencies in the government.

In general, structuring a financial deal is a process of juggling the elements of risk and reward over time. Whatever NASA can do to minimize the risks and maximize the returns over the shortest period of time will increase the level of interest on the part of the financial community. However, within the two extremes of a low risk, high return opportunity and a project with high risk and negligible return, where the bulk of investment situations lie, the mode of financing depends upon the "perceived" level of risk as compared to expected rate of return. Thus, an investor in treasury bills (usually considered a safe investment) expects a return only slightly greater than his passbook savings account, while an investor in a new company producing a new product for a new market expects a substantially larger return based on the anticipated level of risk associated with the project.

In addition to the factors of risk, reward, and time, there is the size of the investment to consider. Two projects with comparable risk-reward ratios will still be handled quite differently if one project requires $5 million and the other requires $500 million. At first glance, it is natural to assume that any project associated with a space station will be a "megabuck" proposition. On the other hand, to a great extent the use of a space station for manufacturing and materials processing, as an example, will

involve new and innovative concepts that may more rapidly emerge from a small group of entrepreneurial engineers rather than from a major corporation. Such small initiatives with such great potential will start with limited funding, low ground-based overhead, and lots of enthusiasm.

If NASA is truly committed to space commercialization in the future, its role may be to create a space processing "incubator" assuming it can relate to the venture capital elements of the financial community accordingly. At the same time, the "incubator" may cost several hundred million dollars to engineer and fabricate and thus NASA may also choose to deal with that segment of the financial community, (i.e., institutional lenders) that handles large investments (oil refineries and pipelines, for example) in an appropriate investment framework.

In bridging the range of investment possibilities, the remainder this report will concentrate on three major mechanisms for business financing and on variations and combinations of the three methods where appropriate. These financing methods include venture capital, R & D limited partnerships, and project financing. Each method is appropriate under different conditions and circumstances; however, considering the breadth of possibilities encompassed by these three techniques, there are relatively few viable business concepts that could not be financed by one alone or by a combination of the three.

IV. FINANCING METHODS

Venture Capital

Venture capital is a subset of equity financing -- in other words, financing involved with selling shares in the ownership of a company among individuals who may or may not be directly associated with the company. The majority of large companies are primarily funded through equity financing with their shares traded publicly either on one of the major stock exchanges or on the over-the-counter markets. The term venture capital is often associated with start-up companies or with companies that are small and have little or no operating history. Therefore by definition, there is greater risk involved with this kind of situation. Add the element of new technology and there is even more risk to be considered. On the other hand, the investors involved with venture capital are generally looking for higher return on their money and are willing to take calculated chances to achieve that objective.

The amount of money involved with most venture capital funding is small by NASA standards. The range is within $100,000 to $10,000,000 with the bulk of the financing occurring between $300,000 and $1,000,000. In this context, why should NASA be concerned with venture capital? As mentioned previously, new commercial technology is most frequently spawned in the venture capital environment. For example, the personal computer industry started in a garage in the Silicon Valley area of California in 1976 and now represents a $6 billion industry growing in excess of 50% annually. To a great extent, space commercialization will require the creation of product concepts which do not exist today. Large corporations will definitely be involved in this process, as are McDonnell Douglas and Johnson & Johnson in the current electrophoresis project on the shuttle. But based on recent past experience, it is more likely that new companies will respond to the challenge faster than large established companies. Facing competition from the upstarts, the large companies will then very rapidly respond to the challenge -- case in point, IBM's reponse to the personal computer market in 1981 after denying its existence in 1978.

Given a viable new product or service, the objective of the venture capitalist is to assist the new company through the risky early years of development and growth in anticipation of taking the company "public", the point when capital is raised through a public offering of stock. At this juncture, the value of the company is recognized in the price of the stock. Additionally, because the stock is widely traded at this point, the initial investors have significantly greater flexibility and latitude in "cashing in" their investment.

However, up to the point of going public, requirements for additional equity capital fall on the backs of the original venture capital group which must either insert additional funds to protect the viability of their initial investment or seek additional investment funds from other venture capital groups, thus diluting their share of the company. When such injections of capital are predictable and according to the business plan, then everyone is happy and content that the company is growing and progressing as planned. Also, if growth and potential profitability are ahead of schedule, the need for additional funds is not begrudged. It is the unexpected "negative cash flows" that make venture capital investors nervous. Outside influences of particular concern include unpredictable supplies of raw material and changing requirements for unique facilities and transportation, problems not unfamiliar to NASA.

In order to overcome this obstacle, NASA must be able to sign a contract which specifies the exact availability of facilities and the cost of those facilities to be used over a specified period of time. NASA, and thus the government, must be held liable for any delays that could affect commercial production schedules to the extent that short term sales revenues are lost and the viability of the company is jeopardized. Without such assurance, no sensible businessman would commit time or money to the space station program.

How can NASA best position its space station program for venture capital investment? Most immediately, by continuing the "joint endeavor" process while turning agreements around in weeks instead of months. In a similar manner, NASA must be prepared to provide space services rapidly and at a reasonable price to an investment community that cannot tolerate bureaucratic delays and that works on a very short, tight schedule with a limited budget. If a new venture calls for a 1990 space station facility at a $5 million annual lease rate, a "technical" or "budget" problem that delays the availability of that space station until 1992 and results in an annual lease rate of $10 million will not be tolerated.

Assuming that NASA can respond to this challenge, NASA must, in addition, sell its space station programs to entrepreneurs and venture capital sources in a manner responsive to their need for facilities. Will a new start company be interested in buying "up-front" a complete facilities module at $200 million? Unlikely. Will they rent or lease space starting at $200,000 per month if they can sell the resulting product for $400,000? There is a strong possibility. At this point, the pertinent questions are:

- can NASA fund the building of appropriate hardware and charge out its usage at an acceptable level so that it can recover its costs?

- if NASA cannot or chooses not to perform this function, are there other entities within the private sector who would willingly perform this function?

- if there are such "third party" opportunities, can NASA in turn respond to their needs?

The second and third questions above will be addressed later in this report. But an important point to make now is that all forms of commercial financing are tied together by common threads of self interest. Therefore, on a more earthly level, a new high technology company will require manufacturing facilities to do its R & D and to build its product. Consequently, the company leases office and laboratory space from a real estate investment company that in turn receives its financing from banks and insurance companies. Thus, NASA is confronted with not only the priorities of the venture capital community but also with how these priorities relate to other financial interests. Similarly, financial institutions involved with setting up limited partnerships and structuring project financing for the fabrication of space facilities must have commercial tenants with a viable application in mind. Indeed, a communications customer may walk in with contracts and commitments in hand. Yet, organizing and cultivating potential new venture concepts, and specifically their financial supporters, will be a fundamental requirement for stimulating the long term development of commercial space activities.

Research and Development Limited Partnerships

As a financial vehicle, the limited partnership has been around for many years. The concept centers on the utilization of funding from a group of investors, known as limited partners, and on the management group, composed of individuals or a corporation known as the general partner, all of whom are organized under specific legal and accounting guidelines. The primary objective of a limited partnership is to provide off balance sheet financing -- in other words, funding not affecting the credit status of the company -- while providing specific tax and income benefits to an otherwise unaffiliated group of investors. Specifically, the investors receive the immediate tax benefits associated with the purchase of hardware and equipment with the additional commitment to receive a specified percentage of revenues from the resulting project over a predetermined period of time. The company presumably does not need or want the tax benefits, avoids the use of debt financing or equity financing, and is not required to indefinitely share

the profits of a specific project or the long term prosperity of the company with the investors/limited partners.

In the past ten years, a variation of the standard limited partnership has evolved which provides specific benefits to those companies developing new high technology products. Known as the R & D limited partnership, it is designed to complement rather than replace conventional equity and bank financing. The R & D partnership is particularly beneficial in that it is designed to efficiently utilize available tax benefits to minimize an investor's after tax capital at risk and thus substantially boost the after tax returns. Furthermore, if the research project proves to be successful, the royalties may be taxed at the long term capital gain rates. Consequently, these tax benefits enable an investor to take financial risks which would otherwise be unacceptable to venture capital as well as conventional equity investors.

The benefits provided by the R & D partnership are based on three major elements of the tax code and related legal decisions. First, the Internal Revenue Code, Section 174, permits an electing taxpayer to currently deduct qualifying research expenditures rather than capitalize them as part of a product's ultimate cost. Second, the tax code permits the partners to be taxed at the long term capital gains rates on the sale of all rights to a patent or patentable property by the inventor or a person who buys an interest in the invention from the inventor before it is commercially exploitable, regardless of the actual holding period. The third element is the decision made by the U.S. Supreme Court in a precedent setting case known as "Snow vs. Commissioner", 416 U.S. 500 (1974) which held that limited partners could offset their income with partnership research or experimental expenditures. This decision also further extended the boundaries of Section 174 to include businesses that have not yet offered any product for sale.

For example, a typical partnership would be initiated by an inventor, who as general partner would contribute his invention or idea while the limited partners provide capital to finance the required research and development to bring the concept to fruition. The partnership subsequently spends the funds for research allocating the resulting tax loss to the limited partners. This loss offsets the limited partners "nonpartnership" taxable income therefore reducing their after tax exposure and thus reducing the perceived risk of the research project. When the concept is perfected and brought to the marketplace, the general and limited partners share the income generated from the sales of the product.

Over the last ten years, many variations to this basic structure have been suggested and tested within the business community. In most cases, the partnership contracts out the

R & D to a research corporation, usually headed by the inventor. This procedure takes advantage of existing facilities, minimizing the requirement for the partnership to invest in new facilities while protecting the "trade secrets" of the inventor. Similarly, rather than manufacturing and selling the results of the research effort, the partnership will sell all rights to the invention to the research corporation/inventor in exchange for royalties based on sales. These royalties usually represent a significant proportion of revenues until the limited investors are paid back for their initial investment. At that point, the royalties decrease to a substantially smaller percentage which, by contract agreement, usually terminate after a specified period of time. In this manner, the inventor maintains control of his company and his technology based products while minimizing external debt. The limited partner/investor minimizes his risk through the tax benefits while obtaining the prospect of above average returns on his dollar if the product is successfully developed. This prospect is particularly enhanced by the stipulation that tax on the royalties will be paid at capital gains rates rather than ordinary income rates.

Although the concept described for creating an R & D partnership is seemingly simple and straightforward, there are legal and accounting pitfalls which can jeopardize the integrity of such a project. Lawyers and accountants tend to get rich in the process, but their advice, gathered from other's experience, will be required in structuring an agreement which meets the requirements of all participating groups including the IRS.

NASA may not immediately appreciate the significance of the R & D partnership in financing the commercial elements of a space station. However, it should be realized that most R & D partnerships stress the development more than the research. In other words, where capital is required to test the feasibility of manufacturing a product or creating a process for manufacturing in space, the R & D partnership may represent an appropriate mechanism for achieving that objective. Again, it should be realized that such financing usually would not stand alone. Somewhere in the process of funding a new business, venture capital will be involved as well as those elements of financing required to fabricate the manufacturing facilities, which for NASA's purposes, would be modules of a space station.

Therefore, in covering the attributes of venture capital and the R & D partnership, the basis for using these financing tools for funding the most promising commercial space activities has been established. The methods for financing the components of the space station will be addressed in an overview of project financing.

Project Financing

Project financing is another relatively simple concept that is utilized by the business community to finance large, capital-intensive projects while minimizing the impact to the sponsor's balance sheet. The basis of project financing lies in the ability to confine the financing to a particular business unit or "project" without recourse to the sponsor. Thus, the project should stand by itself as a viable business concept or have access to specified third party guarantees which will ensure the project's ability to repay its lenders.

Project financing has been successfully utilized by companies involved in the transportation and processsing of new energy resources in particular. The amount of money and the time required to build such facilities frequently places an intolerable burden on a single sponsor unless the risks and rewards can be spread among several other interested parties. Such groups could include insurance companies, upstream suppliers, and downstream customers, as well as the lending institutions themselves. Collectively, the interests of all parties are achieved, usually through intense negotiations and compromise, and the credit viability of the project is established based on the combined qualifications and commitments of its constituents.

Although simple in concept, project financings can become quite complex when the often conflicting goals and requirements of its constituents are considered. Again, the experience of other companies, both their successes and failures, can be beneficial in determining whether project financing would be appropriate for a particular application and in determining how best to minimize delays in completing the transaction.

Criteria for Implementation

As stated previously, project financings generally are associated with capital intensive business concepts that have a lifetime of significant duration. Therefore, it is necessary to consider various criteria for project financing in the context of the project phase in which these criteria are applicable.

For practical purposes, almost all projects can be divided into four distinct phases: planning, engineering and construction, start-up, and operation. The sponsor of the project will initially produce a business plan which will outline in detail the anticipated costs to be incurred, revenues, and milestones for the proposed project. In the case of a space station, the dollar amounts and time periods may vary, but the sequence of events will be the same. Thus during the planning period before implementation of project

financing for a component of a space station, the following criteria will be carefully scrutinized by lenders who wish to minimize their exposure:

- Is the primary sponsor adequately backed by equity funding? (Banks and other lending institutions are not financially backed or organizationally prepared to take equity risks.)
- Are the projections for costs and revenues conservative and based on valid assumptions?
- Is there technology risk? In other words, are there components of the project which are technically unproven and potentially unreliable?
- Are components and raw materials readily available and reliably priced?
- Is transportation for raw material and finished product available and competitively priced and will it remain so for the lifetime of the project?
- Does a market exist for the finished product? If so, is it a mature or immature market that is growing, static, or relatively unpenetrated?
- Is there a threat of technological obsolescence?
- Is the contractor or any intermediary agency considered reliable, cost conscious, and noted for delivering according to contract schedule?
- Are the management personnel experienced? Have they operated similar projects under comparable conditions and what was their track record?
- Is there sufficient insurance to cover losses beyond the control of the operators?
- Is the project going to operate in a stable political environment? In other words, will all types of regulation be anticpated, will all forms of taxation be discounted, and will changes associated with fluctuations in government be minimal?

Leasing

Although debt of some type is present in almost all forms of project financing, various forms of leasing represent an important mechanism for facilitating the flexibility required in capital-intensive project funding. The basic or true lease provides the lessor the opportunity to claim the tax benefits associated with equipment acquisition which he flows through to the lessee in reduced lease payments. The lessee, who might otherwise be unable to take advantage of the tax benefits, thus is able to reduce his cost of financing his business. In a pure sense, the lease is a form of project financing. In a broader sense, the lease is a component of larger, long term equipment acquisition which has become known as project financing in the evolving use of that term.

Leasing typically appears in a project financing in the form of a "leveraged" lease. In this variation, the lessor borrows from 50% to 80% of the funds required to purchase the desired equipment from a long term lender such as a bank or institutional investor. At this point, the simple lease becomes somewhat more complex now that a third party is involved. The debt is secured by a first lien on the equipment purchased and an interest rate is negotiated based on the credit-worthiness of the borrower and the perceived risk of the transaction. The lessor is permitted to claim all the tax benefits of the equipment purchase which will initially reduce any negative cash flow from the transaction even though interest must be paid to the lender. In the short term, the lessee also benefits due to reduced lease rates. Assuming that the use of the equipment progresses as planned, the reduced negative cash flow in the short term will accelerate growth and development of the business to a point where a positive cash flow is achieved at a faster rate. Leveraging also increases the risk asociated with unanticipated losses -- that is, leverage can work in both directions.

In leveraged lease transactions of any significance, there may be a large number of lenders and owners. Thus, frequently, an owner trustee is established to hold title to the equipment and to represent the owners while an indenture trustee is named to oversee the interests of the lenders by holding the mortgages and monitoring the periodic flow of funds. The complexity of such transactions and the resulting legal costs usually limit their use to projects involving major equipment . Hardware for a space station operation would most certainly fall into this category.

Factors that could enhance or expedite the formation of project financing transactions would include government guaranteed debt (i.e., revenue bonds, guaranteed bank debt, etc.) and/or investment tax credit and accelerated depreciation for technology investment. In particular, this is an

area where NASA and the Congress can play the most effective role by providing incentives for the investment community to become involved with space commercialization. New technology areas are always slow to attract investment dollars until one or another factor triggers the interest and awareness of investors. Positive publicity is a very important contribution. In that sense, space commercialization is receiving favorable coverage by the press. However, the public perceives that space activities are expensive and risky and prone to undefined time delays. Economic incentives would go a long way towards changing that image and putting space commericialization into a positive investment environment.

V. SPACE COMMERCIALIZATION: REMOTE SENSING AS A CASE STUDY

Satellite remote sensing, as typified by the Landsat series of satellites, has been utilized and scrutinized for more than a decade. And yet, within the government, very little has been done to understand the commercial potential of satellite remote sensing or to determine how it could be commercialized productively and efficiently. Landsat has been primarily an R & D program with heavy emphasis on the "R" and with only minor attention paid to the commercial "D". Unfortunately, this has left a very promising commercial technology with a very poor foundation for transition to private sector operations. Even the major aerospace contractors, who have been involved with the Landsat program, have a poor understanding of the business opportunities in this field. From their point of view, satellite remote sensing was only important to them in terms of government contracts and not in terms of developing a new market for earth resources information services.

The government, through the NASA Landsat and the NOAA meteorological satellite (Metsat) programs, has contributed significantly to the future economic potential of satellite remote sensing. In spite of this contribution, however, an unfortunate lack of understanding has developed concerning the context in which remote sensing fits into a commercial environment. In NASA's sphere of operation, remote sensing is primarily an aerospace technology. But in the commercial world, remote sensing is a computer and information technology and it should be packaged and marketed accordingly.

Of greater significance, however, is the fact that remote sensing has not been positioned by the government as a potential commercial technology; therefore, it has remained unnoticed by the financial community. Specifically, no government agency has ever conducted market research to define the true potential of an information system based on real-time data acquisition from a network of geosynchronous and low earth orbiting satellites. To a great extent, knowledgeable private sector groups understand that the potential gross revenues derived from all components of an earth (land and ocean) resources and environmental data industry can be numbered not in the millions, but in the billions of dollars annually.

This past underestimation of the commercial potential of satellite remote sensing certainly does not help NASA now when promoting remote sensing as a component of a commercial space station program. Estimates by TRW in their Space Station Needs, Attributes and Architectural Options Study (SSNAAO) indicate that the contribution of the space segment (namely, the sensors and platforms) of remote sensing to overall space station revenues could be as much as $5.15 billion between 1995 and 2000. However, this contribution

to the support of the space station program is highly dependent on aggressive development of the satellite data user market at this time, paralled by a dedicated commitment to developing a commercially viable follow-on to the Landsat program.

The government's past attitude towards remote sensing may be attributed to its orientation toward research rather than business in space. There is also a seemingly "governmental" quality to the meteorological satellite observation process. Nevertheless, it is apparent that the current activities of the Landsat program will be transferred to the private sector within the next several years with other application functions (i.e., ocean and meteorological remote sensing) being assumed by private companies during the latter part of this decade as a function of a gradual transition to commercial operations.

Terra-Mar recognizes that future revenue from appropriate satellite sensors is directly tied to growth associated with the next generation of computer services. In this context, digital satellite imagery will be a valuable source of input into earth resources information services. Within the private sector, the infrastructure for this service capability is now in the development stage. Highly refined applications software for converting imagery into information will soon greatly expand the current limited user base. Furthermore, computer networks and distributed processing will provide convenient access to new markets for specialized earth resources data bases. This is a factual not a speculative scenario that is based on generally accepted trends which are fundamental to all computer service companies.

In building investor confidence in the commercial potential of remote sensing, it is essential to establish the connection between these trends and the commercial opportunities that accurate information generated from satellite imagery will provide. Assessing and analyzing the market becomes an important function of capitalizing a new industry.

Assessing the Potential Market

Previous government studies have at best defined the value of satellite remote sensing in terms of a "cost-benefit" analysis using techniques inappropriate for assessing future high-technology markets. Specifically, the mechanism for gathering information about the future user community -- the market survey -- has misrepresented the substantial potential of an earth and environmental resources information industry. The market survey can be a very useful tool in predicting sales figures, depending upon how the information is gathered and how it is utilized. In the

38-036 O - 84 - 57

case of past surveys of users of remote sensing data, the general questions have been along the lines of "...how would you use remote sensing data", "... how much remote sensing data would you buy", and "...how much are you willing to pay for remote sensing data". The absurdity of such questions can be put into some perspective if one considers how a "potential customer" for computers or plain paper copiers would have answered similar questions in 1950. Most people cannot even begin to imagine how remote sensing data could relate to the way they do business or to how they make decisions.

In order to correctly assess the potential market for remote sensing "information" -- that is, highly processed and refined remote sensing data -- one must ask questions which relate to how people use any type of earth resource information in their business and how critical this information is to their decision making process. This type of information could be as seemingly mundane as a newsletter from the state fish and game department or the morning weather, livestock, and commodities report on the local television news. It could also be as expensive and complex as a $100,000 per year crop forecasting service received daily by a commodities brokerage business. Each use of information is extremely significant for the forecasting of the market for remote sensing derived products. Even this market research is irrelevant if put into a market forecasting model which does not account for the real world environment. In the case of forecasting remote sensing information markets, models which do not include industry concentration (revenues per establishment), user sophistication (ability to utilize and adapt to computer generated products), and technology leverage (growth of computer generated services) should be considered useful to the academic economist but otherwise useless in a commercial environment.

Unfortunately, such an incorrect market analysis has been generated in past market forecasts from current sales of Landsat data from the EROS Sioux Falls Data Center. Sales of products from an R & D system in a format not readily interpreted by the "masses" does not constitute the basis for accurate market projections.

In evaluating market potential, Terra-Mar has assessed the gross requirements of users for all forms of renewable and nonrenewable resource and environmental information in terms of operating revenues which are specifically affected by the availability of that information. Thus, an oil company managing a $100 million offshore oil field may spend $500,000 per year for wave, current, and meteorological information derived from satellite data and associated value-added services. Or, 10,000 commodity brokers may each utilize $50 worth of a commodities information service in making trades equaling $50,000,000.

Based upon the availability of appropriate remote sensing data, earth resources and environmental information services will eventually penetrate and expand these current markets with improved products. Projecting the growth and development of such a business becomes a function of quantifying the size of that potential market and then calculating rates of market penetration based on historically documented algorithms for comparable technologies (namely, those based on computer and communications technology).

Terra-Mar's market projections derived from analyzing these marketing and technological trends provide a positive basis for pursuing commercial satellite remote sensing services. These projections assume an aggressive marketing environment -- one that is unregulated and very competitive. Similar promising revenue estimates for materials processing products and services have been made outside the government. NASA must recognize that the technologies, which are partially the fruit of NASA's own R & D efforts, must be nurtured in an environment stimulated by the application of creative marketing techniques. The creation of the technology establishes the potential of a new business. Application of sound marketing and management techniques makes that potential business a reality.

The Leverage of Improving Technology

To a great extent, growth in the markets for earth resources and environmental information will be made possible by advances in semiconductor and computer technology. The growth in the sales of personal computers from zero in 1976 to over $6 billion in 1983 is indicative of a trend towards less expensive, distributed computing which will shape the marketing strategies for computer services in the future. In essence, the personal computer has created a mass market for software and data services on an individual level. Like the scientific hand-held calculater of the last decade, a high percentage of scientists, engineers, and businessmen will own a desktop personal computer to use in their day-to-day decision making process. It will not be a luxury but a necessity.

In this marketing context, remote sensing data will become an important component of the future information revolution. Terra-Mar has determined that a substantial proportion of important decisions made by the business community are related to having accurate information about the earth's resources or its environment. Improving the raw satellite imagery with value-added services -- essentially, customizing the data to user needs -- will make remote sensing data a strategic element of the future decision making process of international business.

In addition to advances in computer technology, the next decade will see improvements in the methods of deploying orbiting earth sensors. More reliable, interchangeable, and thus less expensive sensor components will be operated from space platforms such as the Fairchild Leasecraft and the MBB SPAS in coordination with manned space stations. On these platforms, scheduled maintenance and repair will prevent the costly loss of satellite sensor systems, as previously experienced with Seasat, for example. The requirement of efficiency and economy will replace the "gold-plated" specifications generated by the previous era of R & D sensors.

Approaching the Investment Community

Unfortunately, the investment community has not been well informed about the commercial opportunities regarding utilization of remote sensing technology. Government officials have not only failed to educate Wall Street but have also failed to understand how private investors can play an important role in developing this strategic technology. As mentioned previously, investors are guided by certain criteria in evaluating prospects for placing their funds.

Four criteria are particularly applicable in the case of remote sensing. First, is the technology far enough removed from research and development that there is small risk of technical surprise along the path to the marketplace? Second, is this a market with substantial opportunity for long term growth? Third, after considering development and operating costs, are revenue projections sufficient to provide adequate return-on-investment (ROI) in comparison with other investment opportunities? And fourth, is there minimal near and long term risk of the type of government regulation that could inhibit earnings growth? In other words, are we dealing with a politically benign technology?

Ten years of successful R & D in Landsat and related environmental satellite programs will provide the basis for initiating commercial remote sensing ventures with little threat of technical uncertainties or unknowns. Solid state sensor technology will minimize many of the risks of mechanical sensors, while improved modes of deployment such as SPAS and Leasecraft serviced through a manned space station can minimize the risks of on-orbit failure.

Discounting the government evaluation of remote sensing generated information markets, private studies such as those prepared by Terra-Mar adequately document the potential of a market for products and services primarily generated from the availability of appropriate remote sensing data. Paralleling other computer generated information service markets, this business should generate approximately $12 billion in revenues (in constant 1980 dollars) from sales of

data, computer hardware and software, and value-added services by the year 2000. Such rapidly growing and sustained market opportunities are currently highly valued by the investment community.

Thus, the projections for revenues and profits become equally appealing as costs decrease with improved computer and sensor technology, while progress along the "learning curve" creates well defined methods for decreasing unit cost for data generation. Subsequently, remote sensing will follow the trend of other computer technologies as near term dominance of hardware sales is rapidly displaced by requirements for software and then raw data, as the market becomes more broad-based and sophisticated in its utilization of available products.

This leaves the fourth factor -- the issue of politics -- as the remaining unknown and the single issue which could inhibit commercial development of remote sensing products and services. The current controversy over the disposition of Landsat 4 and the environmental satellites poses a serious problem for the business community to overcome. Specifically, Landsat 4 and the Metsats are encumbered with technical and political problems which make their transfer to the private sector rather complex. The original value of the satellite and related data processing assets is significant; however, on the open market, that level of technology is considered obsolete. Given the computer technology which is available today and which will make another substantial leap by 1984, Landsat 4/Metsat-type equipment, primarily oriented for R & D applications, could be considered in financial circles to be a commercial liability. There is also a negative stigma associated with "Landsat" as a commercial concept. The entire process of "analysis" has politicized Landsat to the extent that the financial community views Landsat with a certain skepticism -- it is expensive, unreliable, and may entail unknown political traps.

Nevertheless, Landsat 4 and the Metsats do represent a significant contribution to our understanding of the technology associated with developing viable commercial information products. The addition of the Thematic Mapper to Landsat 4 has provided new insights into the potential usefulness of satellite resource surveillance. However, Landsat 4 is not configured to be an operational satellite system, and no investor who is seeking to compete in an open marketplace would consider owning that system. The NOAA and GOES environmental satellites, although existing in an operational environment, are similarly not configured for commercial utilization. The government's preoccupation with "selling" Landsat and NOAA satellites has missed the true objective of promoting satellite remote sensing as a viable commercial technology. Emphasis should be placed on creating incentives for investment in the next generation of reliable and efficient satellite sensing systems, rather

than on unloading the product of past R & D programs. Similar errors cannot be made in developing commercial space station programs, otherwise investors will show little interest in these programs.

The proper government orientation and strategy should be to stimulate the groundswell of value-added activity which is already occurring, thereby increasing revenues from satellite data sales as new applications become entrenched in the marketplace. Strength among private sector operators will eventually permit backward integration into data receipt and archiving as well as the development and operation of orbiting sensors. In this mode, healthy competition will encourage the creation of new applications software as well as encourage the companies with the best capabilities to assume a leadership role in developing a fully integrated earth resources information system.

In this frame of reference, the investment community can properly interact with those private companies, objectively evaluating the strengths and weaknesses of various competing concepts, evaluating their management's strategic planning skills and knowledge of the market, and putting each to the ultimate test -- looking at the "bottom line". The government should not compete with Wall Street in making these decisions. The government's self-interest, as probably the largest single customer for earth resources information services, will be best served by letting the marketplace determine which companies are best qualified to own and operate remote sensing satellite systems. A similar approach would expedite and enhance the investment potential of other commerial space activities.

Creating an Investment Model for Commercial Remote Sensing

Assuming a creative and stimulative transition of satellite remote sensing from current government operation, a remote sensing/earth resources information industry can finance its space segment using many of the techniques and tools outlined in Section IV. A further assumption must be made that the cost of remote sensing systems will decrease substantially during the next decade as improved electronics are incorporated into operational sensing platforms. As discussed previously, this capability will be further improved by the ability of sensing platforms to be serviced on orbit by astronauts from a manned space station. Changes in the competition and cost structure within the aerospace industry will also lead to the availability of space qualified components at prices approaching those for aircraft avionics. Within this structure, multiple sensor "platform" systems will be feasible under project financing guidelines.

VI. SPACE STATION MODULAR FINANCING

Various circumstances may evolve which will dictate the design and operating priorities for space station development. Assuming that commercial applications become a significant factor in the planning process, a strategy must be implemented that will accomodate differing requirements for orbiting facilities by various commercial users. Besides being sound from an engineering point of view, this strategy must also be financially viable. Ideally, early commercial users of an orbiting space station will pave the way for other users. For example, every new technology market has its identifiable source of market leverage. In this situation, communications provides that source of leverage. Or, in the parlance of corporate America, telecommunications could be the "cash cow" of space commercialization and could provide the core facilities to support commercial remote sensing and materials processing projects.

Commonality and interchangeability of hardware will become a key criterion not only for operational convenience but also to minimize fabrication costs and consequently investment risk. Investors will be favorably inclined towards facilities where the risks associated with engineering and fabrication are borne by a number of users. "Custom" facilities have the aura of high cost and unknown operating history. Those risks are commonly taken for granted by NASA but are to be avoided if possible when presenting projects for financing to the investment community. If engineering risks are to be part of any project, they should be "packaged" as part of an appropriate financial vehicle -- namely, venture capital or R & D limited partnerships.

In that sense, for financing reasons the space station should be engineered in a modular framework that is both functional and practical. Individual projects planned for the separate space station modules (or components), and their operating facilities, can then be matched with the financing mechanism best suited for the element of risk and the return on investment associated with that project. In reviewing the space station feasibility studies prepared over the last decade, Terra-Mar has concluded that an appropriate concept reflecting this logical, modular approach is embodied in the "Manned Orbital Systems Concepts Study" (MOSCS) prepared by McDonnell Douglas for NASA in 1975. Vestiges of this philosophy can be found within the reports completed earlier this year in response to the SSNAAO, although there appears to be an inclination to engineer a facility on a more elaborate scale. The reader is referred to the MOSCS Executive Summary for a review of a conceptual approach to a commercial space station which, if repackaged for Wall Street today, would probably be favorably received.

VII. SPACE STATION INVESTMENT SCENARIO

There are many possible variations on how and under what conditions the investment community would participate in some component of commercial space station financing. For illustrative purposes, this section contains an investment scenario in which the previously discussed financing techniques are interwoven into a deal reflecting the priorities of investors as they relate to an actual opportunity. In this analysis, all individuals and companies are fictitious and the circumstances do not represent current or proposed ventures of any kind.

Cast of Characters

Tom Evans	- Senior Chemical Engineer at Consolidated Elctronics Industries
Fred Dexter	- Tom Evans' boss
Roger Barrett	- Fred Dexter's boss and V.P. of Engineering at Consolidated Electronics Industries
Pete Baxter	- Tom's brother-in-law and an investment tax lawyer with Kroger, Michaels & Cresap
Phillip Donley	- President of Aerospace Devices, parent company of Space Facilities Inc.
Bob Lambert	- Board member of Aerospace Devices and retired bank executive
Gary Hansen	- Board member of Aerospace Devices and former president of Crosby Steel
Ted Lambert	- Bob's brother and a partner at Kroger, Michaels & Cresap
Al Pearson	- Pete Baxter's tennis doubles partner and a partner in Advanced Technology Concepts

Tom Evans is a senior chemical engineer at Consolidated Electronics Industries in Lake Pleasant, New York. He has worked for Consolidated for twenty-five years and now heads their semiconductor crystal fabrication laboratory which synthesizes and tests various materials used in semiconductor fabrication. An aerospace buff for many years, Tom has been intrigued by the possibility of growing pure crystals of gallium arsenide in microgravity. He knows that NASA is building a space station where migrogravity experimentation time will be available at a reasonable cost for R & D and

feasibility studies. Thus inspired, he took some of his own time over a three-month period to develop the chemical analysis, engineering fabrication plans, and the business plan for a gallium arsenide crystal growing project which he subsequently presented to his boss, Fred Dexter, for review. Fred was impressed, put his stamp of approval on the project, and referred it up the chain of command to the V.P. of Engineering, Roger Barrett.

Consolidated Electronics, for reference purposes, is a $10 billion conglomerate with investments in everything from aerospace to agribusiness. Forty percent of its annual revenues is derived from government contracts, primarily with the Department of Defense. However, 1986 was not a good year for Consolidated. Hit hard by the unexpected recession, Consolidated got caught with "fat" inventories when contracts were cancelled and anticipated orders did not arrive. In fact, its defense business was the only factor which kept Consolidated in the black for the fiscal year.

Roger Barrett considers these facts as he reviews Tom Evan's proposed project. Roger is also only three years from retirement and is being considered for promotion to Senior Vice President during the next annual review. He decides that he does not want to give the impression to the boys at the top that he is experiencing early senility by advocating any "Buck Roger" ideas in this economic climate. Therefore, he places his REJECT stamp on Tom's proposal and passes it back down to Fred Dexter.

Tom Evans is very disappointed. He thinks out loud, "what a great opportunity for Consolidated to utilize their experience in semiconductor R & D and to get a leg up on their competition. But those guys at the top must know what they're doing -- they really have the big picture."

By chance, Tom tells his story to his brother-in-law, Pete Baxter, who is an investment tax lawyer with the New York investment banking firm of Kroger, Michaels, & Cresap. Pete is intrigued by Tom's project. Pete knows that Tom is the best in his field, and he has a feeling that a recent project in which he was primary legal counsel may be related in some way to Tom's idea.

K.M. & C. acted as an advisor and broker in a project sponsored by Space Facilities Inc., a subsidiary of Aerospace Devices, a $100 million fabricator of specialty electronics components for NASA and the Department of Defense. Aerospace Devices' president, Phillip Donley, wanted to exploit his company's distinctive competence in building custom aerospace hardware in the new arena of commercial space operations. Phil had been impressed two years before at a NASA briefing where the NASA brass really put forth a well-oiled plan for stimulating commercial space activities. Phil organized a plan with his chief of engineering to build

materials processing modules that would be compatible with the space station design established by NASA.

In essence, it was NASA's innovative approach to this design that convinced Phil they were really serious about commercialization. First, they locked in a design within a year of the SSNAAO studies thus giving everyone outside the system a chance to evaluate the design and come up with their own interfacing ideas. Second, the design was a masterpiece of simplicity -- flexible, taking advantage of all that was learned in the Skylab and Shuttle programs, and incorporating the latest advances in computer and electronics technology. For Phil, it was a piece-of-cake to come up with a compatible design that was equally flexible, using off-the-shelf technology and their own ingenuity to fabricate a relatively inexpensive module for materials processing experimentation.

Phil presented the idea to his board of directors. Bob Lambert, a member of the board and retired bank executive, was enthusiastic but had some reservations about getting such a project financed. He told Phil after the board presentation that Aerospace Devices really needed a customer for the module or at least a couple companies who were willing to sign up for long term contracts to rent space on one or more of the experimentation modules. Gary Hansen, another board member and former president of Crosby Steel Corp., had heard that his former company had been doing some microgravity metal alloy experimentation with NASA Marshall and offered to see if they were interested in committing to some long term project. Well, Crosby Steel was quite cooperative, particularly after realizing that all their R & D experimentation could be expensed, rather than capitalized, based on the 1984 Space Commercialization legislation that Congress had passed.

Thus, Aerospace Devices received a contingency "take or pay" contract from Crosby Steel for module rental as well as a similar contract from the National Science Foundation for collective university studies. At that point, Aerospace Devices also established their Space Facilities subsidiary which sought additional potential large and small customers through advertisements in various professional journals. NASA, impressed with Aerospace Devices' concept and their initiative, expedited the engineering review documents and enthusiastically gave the materials experimentation modules their seal of approval.

Then, Bob Lambert stepped back into the picture and got the wheels turning at K.M.& C. where his brother Ted was a partner. Ted and Bob put their heads together and decided that a project financing approach would be the most appropriate form of financing for the materials processing modules. Pete Baxter, Tom Evans brother-in-law, was in charge of writing the legal opinion for the project financing, in

collaboration with Aerospace Devices' counsel, and orchestrating the final negotiations for a leverage lease with General Credit Corp. backed by loans from Gotham National Bank, the lead lender among eight participating banks. Aerospace Devices could not take advantage of all the tax write-offs associated with the fabrication of experimentation modules, particularly the 15% investment tax credit and accelerated depreciation which was also part of the Space Commercialization legislation. Thus, the project financing involved the sale of the modules from General Credit who in turn leased them to Space Facilities Inc. for resale of services to their customers. Outer Limits Insurance, Inc. brokered the insurance covering all risks incurred in transporting and operating the microgravity modules on orbit. So, all issues of risk, liability, and compensation were covered by a complex but mutually acceptable project financing agreement.

In reviewing the project financing documents, Pete Baxter saw an opportunity for his brother-in-law, Tom Evans. Space Facilities was offering special incentives for small experimental users to rent space for 250 hours or more of their microgravity module time. Tom did not have the money or even his company's backing but he did have the reputation and a great concept on paper. Pete called his tennis doubles partner, Al Pearson, who was a partner in the venture capital firm of Advanced Technology Concepts, Inc. (ATC), and arranged a meeting between him and Tom. The meeting went very well and Fred and his partners decided to back Tom's gallium arsenide crystal business, to be known as MicroSpace Devices, with a $1.5 million equity investment -- however, the proof of concept would require up to $6 million in equipment, processing facility time on the Space Facilities' microgravity module, and transportation costs on the shuttle. And there was the issue of release of proprietary ideas from Consolidated Electronics.

Good lawyers and good brokers can solve most problems, at a price. The REJECT stamp on Tom's proposal was his ticket to freedom from Consolidated since employers must either utilize their employees ideas or provide them the opportunity to develop their ideas on their own, according to legal precedent. The $6 million issue was settled with an R & D limited partnership brokered by ATC's parent, Ferrill Bench, and offered through their 276 offices nationwide. With "Space" and "Semiconductor" in the same prospectus title, it was an instant sellout, in spite of all the boilerplate warnings and disclaimers.

Now, hypothetically, we are in the year 2000 and we are reviewing the long term fruits of this initiative. MicroSpace Devices, better known as MSD to the financial community, is a $3 billion annual sales company, dominating the market for ultra fast logic devices, primarily designed for the MEGAVAX type computer that most people wear on their

wrist. Aerospace Devices, referred to as ADI, now has annual sales of a $2.5 billion supplying microgravity manufacturing, processing, and habitation modules to their estimated 2500 customers worldwide. They have also just entered the market for prefabricated hotel modules which they will initially sell to Hilton International. By the way, NASA rents hangar and habitation modules from Space Facilities for their interplanetary exploration vehicles. Collectively, the Gross National Product has been expanded by $100 billion by direct and indirect capitalization expansion due to space industrialization. And the federal government no longer has a national debt, in great part due to the additional tax dollars generated by commercial space development.

For review purposes, the foundations of this free enterprise fantasy may be traced in Figures VII-1 and VII-2 which diagram the ADI project financing and the MSD limited partnership and venture capital funding.

VIII. LEASE VS. BUY: NASA HAS A CHOICE

In the previous sections, it was assumed that NASA would be the prime instigator in establishing a space station for commercial or any other purpose. Supposedly, this would mean that the government would own the space station and, through NASA, would lease facilities and thus provide services for a fee. Conceivably, one could ask whether, on earth, the government should be in the business of building industrial parks and leasing these facilities to the private sector. In reality, although the government does own a large number of the office buildings and laboratories which it utilizes, it also leases a considerable number of buildings from private owners and real estate developers.

It could be argued that a space station is nothing more than an industrial park in space -- in essence, orbiting real estate. Should NASA be doing a lease vs. buy analysis in determining its best utilization of government funds? Perhaps yes. Is there something so overwhelmingly governmental about space that the private sector should not be given the opportunity to take the initiative? Perhaps no. Definitely, the military's requirements for secure facilities may preclude their operation by civilians. If this factor is an overriding consideration in our future space programs, then the government should take the lead in developing appropriate facilities for its own use.

However, if military applications do not represent the primary reason for being in space, the lease vs. buy decision should certainly be considered, particularly if the concept of space commercialization is to be taken seriously. Why? For the reasons brought up initially in Section II. Can NASA guarantee its customers continuity of prices and policy through changes of administration and fluctuations in the attitude of a Congress that continually revises budget priorities? It is extremely unlikely. On the other hand, NASA could lease all or part of a space station from a private financial institution and expect that contract to remain in tact through the lifetime of the facility. That is the reality of law and the art of writing a good contract.

What about the cost? Here, there are trade offs that must be considered. In favor of leasing: deferred vs. upfront payment, tax revenues generated by leasing profits, and interest dollars saved if deficit financing is involved. In favor of buying: elimination of tax deductions associated with depreciation and potential revenues gained from leasing facilities to nongovernment customers. A sensitivity analysis could be run to analyze the effect of various tax considerations and interest rates on this type of trade-off analysis. However, a more appropriate and perhaps less easily answered question would be -- what levels of efficiency and economy could be achieved by an appropriate pri-

vate space station operator as compared to a government agency? Would private lenders backing a private space station operator impose greater discipline on the contracting and facilities management process thus promoting more efficient operations? Would the construction and operation of a private space station be comparable to the manufacture and operation of airliners -- delivered on schedule for the contracted amount, operated and maintained according to strict guidelines motivated by legal, liability, and profit considerations? Would the economies achieved through business and legal discipline reduce NASA's flexibility in accomplishing its stated mission, specifically, leading edge research and development in aerospace applications?

Of course, there is the middle road. The government through NASA could finance the core facilities -- the solar panels, docking ports, cooling and radiation devices, and telemetry facilities -- while the private sector would own and finance its own manufacturing and processing modules.

To a great extent, the answers to the above questions go beyond economics and enter the arena of establishing and perhaps rewriting government policy. However, it should be realized, that the investment community will more readily interface with a system that it understands and respects, namely, a system of binding contracts and economic incentives. NASA's commitment to space commercialization may be judged on the basis of NASA's willingness to play by those rules. The commitment of private dollars to a commercial space station project will be impacted accordingly.

MAN IN SPACE

SPECIAL REPORT:

SPECIAL REPORT: MAN IN SPACE

Space has become as familiar a dateline as Beirut or Moscow, as NASA pushes forward with its most ambitious plans for man in space since the Apollo moon landings. February's historic untethered spacewalk has set the stage for a bold attempt in April to repair the disabled satellite Solar Max. It has also given impetus to President Reagan's call for a space station, where people will live, work, and dispatch manned and unmanned missions to the far reaches of the solar system. In this special report, DISCOVER examines America's manned space program, beginning in Part I with a report on a trouble-filled shuttle mission that was highlighted by one symbolic and glorious moment. Part II previews the Solar Max rescue, while Part III describes the proposed station in space. Finally, in Part IV, some thoughts on the manner of it all.

PART I: THE MISSION

IN THE ARMCHAIR OF THE GODS

The first solo voyages by untethered astronauts and a misty Florida landing redeem a frustrating shuttle flight

In a giant leap for American spacefarers, Bruce McCandless (above) and Robert Stewart (below) flew untethered from the shuttle in NASA's new jetpacks

BY DENNIS OVERBYE

Sunlight, creeping around the blue limb of the earth 175 miles below, began to wash over the hull of the space shuttle *Challenger* as Bruce McCandless, in the shadows of the cargo bay, asked permission to abandon ship. "I'm going to head on out of the bay," he crackled, "with your permission." With his left hand he pulled up on a small handle on the armrest of his square white backpack, which looked for all the world like a bulky, legless chair. A burst of compressed nitrogen gas shot from tiny thrusters, and McCandless rose head first out of the shuttle, his dangling legs silhouetted against the bright cloud tops of the earth. As he cleared the bay, the astronaut twisted another knob on his right armrest and flipped to face the shuttle. Then he backed cautiously off into the void, dwarfed by the blackness around him as he receded. "This is neat," he reported. Then, looking down, he exclaimed, "Looks like Florida—it is Florida! It's the Cape!" Sailing over the clouds at 17,000 miles per hour, McCandless had become a human spaceship.

The image of that moment will linger as long as humans fly and dream of challenging the stars. Powered by Buck Rogers backpacks, known as manned maneuvering units (MMUs), McCandless and fellow astronaut Robert Stewart became the first human beings to venture from their spacecraft without a lifeline. Their untethered flights, their ability to navigate freely, away from the shuttle, cleared the way for a host of new activities in space. Among them: the first space rescue—the scheduled capture and repair in April of the disabled Solar Max astronomical satellite (see page 20)—and the assembly of an American space station by the early 1990s. Said McCandless, "We've opened a new frontier."

For much of *Challenger's* eight-day flight in February, it hardly seemed that way. Two $75 million communications satellites were lost in space; the shuttle's robot arm developed a bad wrist; a $450,000 balloon exploded in space; the shuttle toilet clogged again; and on its long-awaited, first-ever landing at the Kennedy Space Center in Florida, the shuttle smacked into a bird.

NASA had been determined to get the first flight of 1984 off the ground on time and successfully, especially after President Reagan, only a week before lift-off, announced his support for the agency's long sought space station. And *Challenger* did roar aloft on time on February 3. Heading the five-man crew on his second shuttle flight was Vance Brand, 52. Assisting him were pilot Robert "Hoot" Gibson, 37, and mission specialists McCandless, 46, Stewart, 41, and Ron McNair, 33.

The first order of business was to launch the communications satellites: Westar VI, owned by Western Union, and Palapa B2, belonging to the Indonesian government. To do their job of relaying data and communications, such satellites have to be in geosynchronous orbit, 22,300 miles above the Equator, where their orbital motion just matches the earth's rotation and they hover over the same area of the globe. After being sprung from the payload bay, the nearly identical satellites were to be carried into high orbit by bulbous little booster rockets known as PAMs (payload assist modules). The same combination had worked well five times on previous shuttle flights. On the first

McCandless in space: "Are you going to want the windows washed while I'm out here?"

day, however, after being deployed flawlessly from the shuttle, Westar disappeared. NORAD radars found it, in good health but useless, in an elliptical orbit that took it to a maximum height of only 1,400 miles.

While engineers huddled over data from Westar and checked out the satellite in an effort to find out what had gone wrong, the Palapa launch was postponed and the crew moved to their next task, practicing approaches to another spacecraft. The plan was to launch a Mylar balloon 6.5 feet in diameter from the cargo bay, back away 100 miles or so, and then close back in on it using radar and star trackers. The balloon was in a canister that was supposed to be yanked open by stays as it left its cargo bay cradle, the way a static line opens a parachute. Instead, the stays lifted off as well. Then, reported Brand, "it blew up." Luckily, the crew was able to track a piece of the balloon and gain confidence that the radar will work on the Solar Max mission.

Finally, when technicians were unable to find anything wrong with Palapa, Indonesian officials gave the go-ahead for launching it. A television camera on the end of the shuttle robot arm relayed pictures of the PAM firing, which seemed to fade too soon. Sure enough, Palapa too was lost and then found, also in a low elliptical orbit. On both satellites, the booster rocket had apparently fired for only about 15 seconds instead of 85 as planned.

The succession of glitches cast a pall over *Challenger*, but the crew could still look forward to day five—to the debut of the manned maneuvering unit and a whole new way of flying. Each of the $15 million bulky white backpacks, built by Martin Marietta, runs on compressed nitrogen, which is squirted out of 24 little vents in response to the hand controls. Were an astronaut to keep the throttle down all the way until he ran out of gas—about four minutes—he could accelerate to a top speed of about 45 miles per hour. At that pace, he could never outrun the shuttle, which could quickly catch up to him if he got into trouble and scoop him up in the cargo bay. For that reason, NASA felt no need for McCandless or Stewart to use tethers, even on the MMU's maiden flight.

For McCandless, the morning of day five had been a long time coming. The son and grandson of navy officers, an avid environmentalist, and past president of the Houston chapter of the National Audubon Society, he graduated second in his class from the Naval Academy, and flew Navy jets before becoming an astronaut in 1966. This was his first space flight, and it was fitting that he test-fly the MMU because for almost all of his years as an astronaut he had been involved in designing and testing it. Says Johnson Space Center engineer and jetpack designer Ed Whitsett, "Nobody has left his stamp on any instrument in space like Bruce has left his mark on the backpack."

As Stewart watched, McCandless climbed into his backpack and checked out the controls while it was mounted in a wall rack in the cargo bay. Then he floated away from the wall and began flying around the bay. Meanwhile, Stewart practiced manipulating tools in zero gravity at work stations designed to resemble satellites that astronauts hope to repair in space some day.

McCandless's historic first voyage took him 150 feet away from the mother ship and lasted about twelve minutes. Scudding alone and tiny over the cloud tops far below, he looked like nothing so much as a Zeus blown by some cosmic gust from his Mount Olympus perch, throne and all.

After moving as far as 320 feet from the shuttle, he approached again and asked, "Are you going to want me to wash the windows or anything while I'm out here?" His kind offer refused, it was Stewart's turn to take the backpack. "Enjoy it," said McCandless. After repeating warmup maneuvers, Stewart headed into the void at the brisk speed of .7 miles per hour (relative to *Challenger*), prompting Brand to tell him to slow down. After pausing at 150 feet, Stewart ranged out to 305, and then came safely back.

McCandless's fun was not over. He stuck his feet into restraints clamped onto the end of the robot arm, and was given a ride around the cargo bay by McNair, operating the arm from inside. Anchoring themselves on the arm will give future astronauts leverage when they do work in space. "Just remember," McCandless warned McNair, "one false move and it's *plop*."

After a day of rest, McCandless and Stewart took another space walk, but trouble struck again. So astronauts could practice grappling with a rotating object—like Solar Max—McNair had planned to lift up a German instrument platform (used to float instruments temporarily in space) out of the cargo bay and spin it on the end of the robot arm. The platform was equipped with a grappling pin, and the astronaut carried a grapple similar to the one on the end of the

robot arm. But one of the arm's wrist controls would not work, and controllers decided not to press their luck. McCandless and Stewart, taking turns flying the second of the two backpacks on board, practiced docking to the stationary platform, and NASA pronounced itself satisfied. As they were finishing up, a loose foot restraint—a platform about the size of a bathroom scale—floated out of the bay. Deciding that there was enough junk in orbit already from exploded balloons and dud rockets, pilot Brand sidled the shuttle over to the runaway equipment, and McCandless slid along a handrail to the rear of the cargo bay and plucked it out of space. Said McCandless, " 'We deliver' may have been the motto of the fifth shuttle crew, but we also pick up."

Pressed on how it felt to fly the backpack, Stewart modestly explained that he considered himself merely a test pilot flying a new machine. Then Brand added, "But in the cabin, they call each other Flash Gordon and Buck Rogers."

There was one more milestone for Buck, Flash, and the rest of the crew, one that long had eluded NASA: landing the shuttle on a new three-mile runway at Kennedy Space Center, where shuttles are launched. Bad weather last June prevented the crew of the seventh shuttle mission from landing in Florida, but this time the skies were clear. NASA patrols made several sweeps during the night preceding the landing to hustle away any alligators or wild pigs that might have wandered onto the runway from the surrounding wildlife sanctuary (none had). *Challenger* re-entered the atmosphere near Indonesia, swooped across the Pacific, the Gulf of Mexico, Florida, and out to sea, did a U-turn, and sailed down over the palm trees through a flock of birds. As the shuttle touched down, two and a half inches off the center line of the runway, vortices of fog twirled at the ends of its wings. After an initial examination, the spacecraft was pronounced to be in perfect shape, except for four tiles (broken, NASA thinks, by ice during a water dump in orbit) and its landing brakes, which have to be replaced.

As DISCOVER went to press, NASA and industry engineers still had not pinpointed the cause of the twin satellite failures, but shuttle head General James Abrahamson vowed that "every available resource will be used" in the investigation. NASA suspects that the solid-fuel mixture used in the PAM rocket engines may have been defective, and blew apart, prematurely snuffing out the rocket flame. Pressed to find an answer before the next satellite launch from the shuttle, scheduled for June, the agency made plans to test-fire other rockets packed with fuel from the same batch.

Western Union and Indonesia stand to collect $75 million each from insurance underwriters, who warned that as a result, insurance costs for communications satellites would go—well, sky high. Although NASA claims it is not responsible for what happens once a satellite leaves the shuttle, the agency is concerned that it might lose customers. In fact, Westar was once slated to be launched by the trouble-plagued European Arianne rocket, but Western Union backed out of its date with Arianne to take advantage of an earlier slot with the shuttle.

NASA is already investigating the possibility of retrieving the satellites. Says Abrahamson, "If they ask us—seriously—then serious planning could begin." Controllers would have to use maneuvering thrusters to ease the satellites into circular orbits, where the shuttle could rendezvous with them, and to brake their rapid spins. Also, NASA would have to design special grappling hooks to snare the satellites, which have no pins for the robot arm to grab on to.

Challenger is scheduled to fly again on April 4, the shortest turnaround time yet for the shuttle. Not having to transport the orbiter from California, where most previous flights have landed, will give NASA an extra week to prepare for its April date with Solar Max.

PART II: THE RESCUE

NEXT STOP: SOLAR MAX

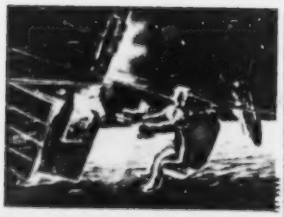
In April, five astronauts will make a dramatic house call to a sick satellite, wrestle it to rest, and perform electronic surgery in space.

Davy Crockett and Paul "Bear" Bryant both won their reputations wrestling bears, but early in April astronaut George Nelson, 33, should go them one better by engaging in the space-age equivalent: wrestling a 5,000-pound satellite orbiting 305 miles above the earth. Armed with only the microcomputer brain and tiny nitrogen thrusters of his manned maneuvering unit—the rocket backpack tested successfully on *Challenger's* February flight—Nelson will try to still a wobbling, disabled space observatory known as the Solar Maximum Mission, so that it can be grabbed by the shuttle's robot arm. Nelson's encounter will be the highlight of the most dramatic space mission ever planned: the capture and repair of a satellite.

The designers of Solar Max, as it is affectionately known, had no such spectaculars in mind when they launched it on Valentine's Day 1980 with a battery of instruments to photograph and analyze the mysterious storms and explosions that wrack the outer layers of the sun every eleven years, when the number of sunspots, which rises and falls cyclically, reaches its crest. This activity—called the solar maximum—lasts two or three years thereafter; the sun shoots out particles more frequently and savagely than usual, bombarding the solar system and disrupting communications on earth.

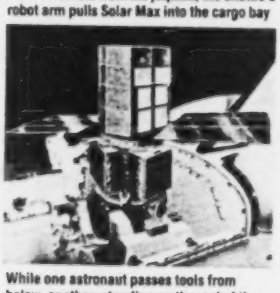
Solar Max was the first satellite built with standardized, easily replaceable plug-in modules containing circuitry to perform such chores as controlling electrical power and keeping the craft and its instruments pointed in the right direction. In anticipation of the shuttle, which did not venture into space until 1981, the satellite was also equipped with grapoling pins for the shuttle arm to hook onto.

Scientists had planned to bring Solar Max back to earth in 1986, say, after its mission was completed, but after only eight months a fuse blew in the satellite's pointing system, leaving the $200 million spacecraft drifting aimlessly, and setting the stage for April's Buck Rogers heroics. The capture and repair have been practiced move by move, screw by screw, in underwater tanks, flight simulators, and, most recently, in space, when the crucial backpacks were tested.



Dodging the spinning solar panels, an astronaut moves in and prepares to latch onto a grappling pin on the side of Solar Max

After the astronaut has stabilized the satellite with bursts from his jetpack, the shuttle's robot arm pulls Solar Max into the cargo bay



While one astronaut passes tools from below, another, standing on the end of the robot arm, begins working on Solar Max

It should all become reality early in April, when a five-man crew led by Robert Crippen (who has already flown on two shuttle missions) is scheduled to blast into a 305-mile-high orbit, the highest the shuttle has yet flown. Along with Nelson and Crippen, 46, will be pilot Francis Scobee, 44, and mission specialists Terry Hart, 37, and James van Hoften, 39.

On its third day in space, *Challenger* will rendezvous with Solar Max, which is spinning slowly, at one sixth of a revolution per minute, its solar panels sweeping space like giant fan blades. While van Hoften watches from the cargo bay, Nelson, in his rocket backpack, will fly about 200 feet over to Solar Max, dodge the delicate, slowly rotating panels, and grab onto one of the grappling pins with the special adapter used in February's practice sessions. Then, by firing his backpack thrusters in the direction opposite from Solar Max's spin, he will halt the satellite's rotation. *Challenger* will approach closer, and Hart, operating the robot arm, will grab Solar Max. Nelson will let go and follow along, he and van Hoften ready to give a helpful nudge, as Hart sets the satellite down into a special cradle in the cargo bay.

Then Nelson will doff his backpack and both men will pick up their tool kits. Riding the end of the robot arm as he would a cherry picker, to get around the 18-foot-high satellite, van Hoften will replace the 500-pound module containing the broken pointing system with a new one. That is the easy part. NASA would also like the astronauts to replace the failed electronic innards of Solar Max's coronagraph, a camera that photographs the hot, tenuous, outer layer of the sun. But the coronagraph's electronics were not designed to be replaced in space. To get at them, van Hoften and Nelson will have to cut Solar Max's insulation, undo 22 little screws, unplug connectors, and cut wires, and then reconnect them all—while wearing bulky spacesuit gloves. That task, in addition to the capture effort, is too much to do in one six-hour outing.

Most of the coronagraph work will be done during a second space walk, on the fifth day. In between space walks, while the repairmen rest, *Challenger* will climb yet higher, to 330 miles, in order to get the heavy satellite above the outer fringes of the atmosphere—and thus clear of atmospheric drag—when it is finally released. After Solar Max scientists at the Goddard Space Flight Center in Maryland have certified the satellite's health, Hart will lift it back out of the cargo bay on the sixth day and cast it loose to begin scientific life again. The shuttle will cruise near by for about eight hours to make sure Solar Max is back in good health before the crew begins making preparations to come home.

What if the astronauts are unable to fix Solar Max? They will stow it in *Challenger's* cargo bay and bring it back to earth to be repaired and returned to orbit on a later shuttle mission. Despite this contingency plan, NASA thinks that the ailing observatory will need only outpatient care. *D. O.*

PART III: THE SPACE STATION

WELCOME TO THE COSMIC MOTEL

NASA plans to build a permanent outpost in the heavens as a home for astronauts, a lab for scientists, and a factory for space industry

BY NATALIE ANGIER

Years and years from now, when people can vacation in a lunar lodge, mine the moons of Jupiter for minerals, and wear silver jumpsuits to work, they will look back on the twentieth century and try to date the beginning of the space age. Some, no doubt, will point to Sputnik, Yuri Gagarin, and John Glenn. Others will recite Neil Armstrong's quote about small and giant steps. But at least a few will cast their votes for the moment when Bruce McCandless levitated out of the space shuttle like a magician's assistant, spinning and rolling as gracefully as a young Rudolf Nureyev. Freed of the tethers that had chained astronauts to their craft in the past, McCandless was at home in space. All he lacked was the house.

If Ronald Reagan has his way with Congress, such a house will be built by 1992. In his State of the Union speech last January, the President announced that he would order NASA to begin construction of a manned space station—a project that will cost at least $8 billion. "This nation is at its best when it dares to be great," he declared. "We can follow our dreams to distant stars, living and working for peaceful economic and scientific gains." By committing the country to a major space-capade in what is not coincidentally an election year, the oldest president ever allied himself with the youngest ever; Reagan's address sounded distinctly like John Kennedy's "land a man on the moon" speech of two decades ago.

At space centers around the country, corks popped and NASA staffers hugged each other: the announcement had ended agency head James Beggs's three-year plea for space station dollars. By NASA's reckoning, the station is the next evolutionary step in space science and exploration. Through its portals, the agency insists, manned spacecraft will depart for the moon or even Mars at a fraction of the cost of launching such expeditions from earth, and technicians will haul in and repair wayward satellites. In its compartments, astronauts and scientists will conduct important experiments in fields ranging from astronomy to chemistry; unfettered by the earth's gravity, industry will manufacture better computer chips and concoct new chemicals. Industry had other reasons to cheer. Boeing, Rockwell, and the other aerospace companies hope to benefit from fat contracts that the space station project will send their way.

Yet not everybody is celebrating. Why a manned space station? many scientists wonder. What in the world are we going to do with it? Think of how many fellowships $8 billion would buy, or telescopes, or nuclear magnetic resonators. "There's plenty of study and experimentation to do before we need [the space station]," said Victor Reis, former assistant director of the White House Office of Science and Technology. "What corporation would spend billions to construct a plant before either the manufacturing technology or the market were even established?" Even the proponents of high-tech wizardry at the Pentagon see no need for a space station. Still, Congress is likely to approve the initial $150 million requested for 1985, which will enable NASA to settle on the most viable blueprint.

The basic design is set: the station must include one living and dining module—called the "habitat"—one or two intercon-

Reported by Sue Butler Hannifin and Geoffrey Leavenworth

nected laboratories, a factory, a storage center, and a sort of garage, where the shuttle can dock. Solar panels will provide the power. Within these specifications, however, the possible configurations are nearly endless. Now comes the hard job of deciding on one that might work. If all goes well, construction will begin in 1987. Components will be hauled about 250 miles above the earth in a space shuttle's cargo bay, and then pieced together, like a giant Lego set, by the astronauts. The final component should be snapped into place just in time for the 500th anniversary of Columbus's discovery of America, at which point even today's grumpiest scientists and Pentagon officials are likely to find ways to put the station to use. "My suspicion is that the space station is like the telephone," says Gerald Griffin, director of the Johnson Space Center. "No one thought they would need it when it was first invented, but once it was developed, everyone found they couldn't get by without it."

The notion of a manned space station is not new. More than a century ago, the Boston clergyman Edward Everett Hale described in detail how a huge brick sphere could be launched into global orbit, to guide sailors lost at sea. Writing for *Collier's* magazine in 1952, the great rocket designer Wernher von Braun declared that "scientists and engineers know how to build a station in space that would circle the earth 1,075 miles up. The job would take ten years and cost twice as much as the atom bomb"—or $4 billion (in 1952 dollars).

In fact, America has already experimented with a space station of sorts. In 1973, NASA launched Skylab, a cigar-shaped craft about the size of a three-bedroom house. Trios of astronauts spent up to three months at a stretch working there, and though most of the news was eclipsed by Watergate, the scientific results were impressive: x-ray photographs taken of the sun revolutionized theories about the corona and solar wind, while medical experiments revealed much about the body's reactions to weightlessness.

Skylab crashed to earth prematurely in 1979, when particles from solar storms caused the atmosphere to expand into its path, decaying its orbit. But even if Skylab had remained aloft longer, it would not have been enough to sate the imagination of NASA engineers, who felt that a permanent station in space was the logical next step after the moon landings. Designers proposed ever-grander schemes. Original plans for a station housing twelve-man crews were expanded to provide for 50 or even 100 people, including mess attendants, storekeepers, a barber, a chaplain, and a psychiatrist. Crew members would work eight-hour days—Skylab and shuttle astronauts put in twelve-hour shifts—after which they would retire to the gymnasium for a workout, or to their private cubicles, where they could read or watch television. Rooms would be decorated in restful, easy-on-the-eye colors—light blue or camel—and lighting changes would simulate day and night. A reusable vehicle would shuttle the astronauts back and forth from the earth.

But Vietnam caught up with the dreamers. The government decided that it needed only the shuttle half of the proposal (the half the Pentagon wanted), and vetoed the notion of building any station at all, let alone an entire suburban outpost. NASA did not abandon its hopes, though; like a good Zen master, it was prepared to wait as long as it had to.

Beggs and his assistants never flagged in their campaign for the space station. They toured the country, lecturing about the space station to aerospace and engineering groups and periodically discussing it with Reagan or his aides. If the manned space station seemed impractical, then NASA was prepared to build an unmanned platform, which could be converted later: the important thing was to put some permanent hardware up there. Many times it looked as though the President was almost convinced. When he showed up at a shuttle landing in the summer of 1982 to give a "Welcome home, astronauts" speech, many people thought he would use the occasion to give the space station a green light. But Reagan was noncommittal. His science adviser, George Keyworth, remained opposed to the space station, insisting as recently as a year ago that it "would be a big step backward."

Nobody is quite sure when or why the big change of heart occurred. Some think that Reagan took his first serious look at the space station proposals last winter, when former astronaut John Glenn was considered the biggest threat to his re-election. In June 1983, while addressing a group of mechanical and automotive engineers, Keyworth pulled an unabashed about-face, saying that a space station was a good idea, but not enough: "A space station is only an intermediate step in a more ambitious goal of exploring the nearby solar system." Perhaps the most decisive factor, though, was a report published in December by the congressional Office of Technology Assessment, which has this unsettling message to convey: "Soviet commitment to a permanent human presence in space contrasts with the absence of long-term U.S. goals." In their plodding, bearish fashion, it seems, the Soviets are pulling ahead in "space habitation"; they

SPACE may soon use space platforms to launch manned ventures to other planets, or even the moon—an orb heretofore under the stewardship of the United States. Spurred by the adrenaline of competition, Reagan decided to move. One amusing story has it that when he told the penny-pinchers at the Office of Management and Budget of his intention to authorize the project, David Stockman kindly reminded him of the deficit. Reagan replied with a grin, "Imagine what would have happened if guys like you had interfered with Columbus asking Queen Isabella and King Ferdinand to help him go to the new world."

After brief sparring between Houston's Johnson Space Center and the Marshall Space Flight Center in Huntsville, Alabama, for the lion's share of the project, Beggs appointed Houston the lead center. Nevertheless, all NASA's creative talent is sure to be tapped: the planned space station, while not as grandiose as earlier schemes, will still be enormous, and enormously complex.

The total package will house half a dozen people, weigh about 180,000 pounds, and be cozy enough inside for shirtsleeves. A central computer will control the climate in each section, ensuring that working spaces will be warmer, sleeping areas cooler, and the labs housing electronic equipment nippiest of all. Astronauts will stay for three to six months, dining on reasonably tasty cooked food rather than the "nutrition pill" (although NASA hopes some day to develop eatable algae that can be grown in space). There will be hot and cold water, and the air will be a mixture of oxygen and nitrogen, just as on earth. Because water and oxygen storage takes up so much room, Clarke Covington, manager of the space station project at the Johnson Center, advocates the development of a "closed-loop system," which is jargon for recycling the air and water on board. "For water, you take the humidity from the air, and purify urine and waste water with some kind of vapor distillation system," he explains. "The method would be initially expensive, but worth it over the long haul."

How to connect the modules has not yet been decided. The Marshall Center recommends arranging the pressurized cabins in a giant circle around a "multiple berthing adapter," which would serve as a kind of central lobby. Johnson engineers would string the sections together caterpillar-style.

Hovering in orbit near by would be one or more free-floating unmanned platforms. Telescopes and other delicate instruments could be put out there so that they are not disturbed by astronauts moving around in the station.

The most exciting invention to come out of the project so far is a new kind of solar cell. The space station will need up to 100 kilowatts of power—enough juice to supply the needs of a small neighborhood. If normal silicon cells were used, the array would have to expand over an area the size of several football fields. Instead, NASA has designed a cell made of gallium arsenide, which is more than twice as efficient as silicon in producing electricity; the new cells will convert about 23 per cent of the sun's rays into electricity, compared to the 10 per cent that Skylab's solar panels were able to harness. The final array of cells will be no bigger than 20,000 square feet—about half a football field.

Besides the stationary labs, NASA plans to have on board a couple of roaming gadgets now under development at the Marshall Center. One is the "orbital maneuvering vehicle" (OMV), an unmanned spacecraft only 15 feet wide and 3 feet high. Boosted by 6,700 pounds of propellant, the 10,500-pound OMV will fetch

broken satellites traveling as much as 1,500 miles above the earth and bring them back to the station for repairs. Another possible craft (not included in the present budget) is a manned "orbital transfer vehicle," which would allow an astronaut to visit a satellite wandering uselessly in the wrong orbit (like the Westar and Indonesian satellites launched by *Challenger* in February) and attach a propulsion system that would shove it into its proper path.

Apart from rescuing the flubbed projects of past shuttle missions, how would the astronauts spend their days? NASA has a long list of possible activities. One lab on board will be devoted to animal and plant research, with facilities to house as many as four monkeys and 200 rats. Another room will be set up for laser, electronic, and similar high technology experiments. Says Dave Wensley, chief engineer of the space station at McDonnell Douglas in Huntington Beach, California, "There are certain things in science for which having a man available is a distinct advantage. On Skylab, the astronauts made more discoveries about the earth's oceans than were made by any other means at that time."

NASA also hopes that industry will invest in the station. McDonnell Douglas, together with Johnson & Johnson, plans to produce rare drugs using the technique of electrophoresis in a free-flying module that may or may not link up with the station. In electrophoresis, a current of charged particles is passed through a moving solution of protein, blood serum, or a similarly complex mixture in order to separate the different compounds present according to their electrical properties. Terrestrial gravity severely limits the efficiency of this sifting, as well as the purity of the resulting constituents; chemicals tend to spread and smear together. In the weightlessness of an orbiting space station, an electric current can separate compounds 700 times faster and with a fourfold jump in purity. The two giant corporations already have tested the idea aboard the space shuttle, and found that it has great potential. "We can speed up research drastically," says James Rose, director of Electrophoresis Operations in Space (EOS) at McDonnell Douglas. "For every new chemical created on earth, we could make five in space." Among the pharmaceutical possibilities: insulin, interferon, and various growth hormones.

The space agency has other suggestions for industry: optical fiber production, laser communications testing, ultra-pure computer chip manufacturing, and much more. Investing in space is serious business though; McDonnell Douglas will not discuss figures, but the EOS will certainly cost well into the multimillion-dollar range—quite a sum for companies that have been reluctant to renovate existing plants on earth. For now, even the richest corporations are taking a "wait and see" approach.

It is because of the uncertainties surrounding the manned space station that so many scientists oppose it. James Van Allen of the University of Iowa, who discovered the radiation belts around the earth, pooh-poohed the projects proposed for station-based astronauts as "busywork." Von Eshleman, director of Stanford's Center for Radar Astronomy, insists that "technological thrust is better served by unmanned space exploration than by manned." Last year, a team of 40 students and four professors at Stanford conceived an idea called the Pleiades Project, a flotilla of unmanned platforms bearing diverse scientific experiments, which would cost a fraction of NASA's plan. Moans Eshleman, "When you have a major emphasis like a manned space station, it consumes so much of the major funding that other sciences suffer."

Secretary of Defense Caspar Weinberger remains a staunch foe of the space station, manned or otherwise; he is afraid that it will pull money away from other NASA projects crucial to the Defense Department. Days after the State of the Union address, he wrote a letter to Beggs restating his opposition to the project. Ironically, Weinberger's opposition may aid NASA's cause: the space station will not bear the stigma of being part of the huge defense budget.

Meanwhile, Reagan is sending Beggs on a diplomatic tour of Europe and Japan, in an effort to drum up foreign support—and money—for the space station. If all goes well over the next few years, the men and women who now venture into the cosmos like nervous tourists to an alien land will be able to kick off their shoes and make themselves at home in their motel in the sky.

PART IV: THE FUTURE

THE LAST FRONTIER

This is not an era of bold dreams or imaginative causes. Today, in our hopeful moods, we are content to try to preserve the world rather than transform it—or rush madly to the far ends of it, propelled by the sheer romantic exuberance of exploration. *Star Trek*, after all, was a product of the Sixties, Captain Kirk a Kennedy reaching for the stars. We are grown up now, and practical.

In February, however, we were transfixed by images from space that seemed out of a dream: Bruce McCandless, launched slow-motion into the void, a human satellite, suspended like a white god above the blue curve of the earth. We had seen those images before only in movies like *2001*, or in our schoolboy imaginations when we read science fiction. Many of us who report on space have been holding our breath for the past few years as the space program rose from the pit of inactivity that characterized the years after the last Apollo mission, half expecting the whole enterprise to sink back again. But the shuttle program has flourished, and science journalists suddenly find themselves commuting almost monthly to Houston, and thinking about installing permanent telephone lines at the Kennedy Space Center. The future has arrived almost unnoticed. Shuttles do not yet fly as often or as profitably as NASA wants, but it no longer seems absurd to think that human beings could revisit the moon or set foot on Mars by the end of the century.

So now it is time for the next step, a space station, an orbital waiting room for the deep-space bus, a permanent microgravity playpen for science, a platform from which to look over the health of Spaceship Earth. That is not a big dream; it is no call to arms like a manned Mars mission or a moon colony, each of which would cost tens of billions. The station's $8 billion price tag—a tenth of a per cent of the federal budget for eight years—is not likely to be felt by taxpayers beleaguered with a $1.5 trillion weapons build-up.

In fact, the amazing thing about NASA's proposed space station is how sensible and modest an idea it is. The American space program has in the past been characterized by spurts of grandiose ambition, followed by the distressing slashes of budget knives, and depressing slowdowns by each new administration, perhaps because we have never decided what space is for. Is it for Cold War competition? Is it for science?

Americans view space differently, and less practically, from their Soviet counterparts, who have forged ahead slowly but relentlessly. That may be because space is the extension of the roamings of a restless people—a frontier, if you like. To Americans, the future has always been represented by someplace to go, the next California or Alaska. Space is the connection between our past and our future—a connection brilliantly evoked by the cowboy test pilots portrayed in *The Right Stuff*. We cheer the Voyager images of Saturn and the Apollo views of white-suited men shuffling in the lunar dust because we are used to looking at godforsaken wilderness and imagining where the tennis courts will go. We have lurched rambunctiously upward and outward with our hearts as much as with our heads. But now we are grown-ups, ready for an aluminum-covered cottage in the sky with a silicon roof.

Still, there are critics. Some think a space station is boring, not ambitious enough to stir the American people. Others say it is too ambitious and expensive in a time of $200 billion deficits. Some of the doubters are space scientists, whose reservations were summarized in a report of the National Academy of Sciences that stated that there was no immediate scientific need for a space station. They fear that the house in the sky could, on balance, be harmful to science. For example, NASA-supported science projects designed to take advantage of the space platform would be hostage to delays in its development. That is what happened when the space shuttle was being built; spacecraft intended for launch by the shuttle languished as the shuttle program fell months and then years behind, and planetary exploration nearly died. Scientists also fear that money for the station will be diverted from scientific endeavors, as it was during the shuttle era.

NASA claims that it will not put scientists through the wringer again. The same 1985 budget that allots $150 million for the space station also includes funds for a new Mars probe and an upper-atmospheric research satellite, but it also slashes $5 million from money for analysis of previous missions. That has led some scientists to complain that the squeeze may already be on. It would be a shame to pay for the space house by selling the solar system.

But there is not enough money in planetary exploration to pay for a space station even if all the probes were canceled. Conversely, the bulk of the money saved by not building a space station would not be spent on science (or on mass transit or education, for that matter).

Unlike the shuttle, the space stations being studied involve little unpredictable new technology, no expensive problem children like delicate thermal tiles that chip and fall off, or fancy new rocket engines. The essence of a space station module was actually flown in space last December. It was called Spacelab, a pressurized scientific laboratory that sits in the cargo bay of the shuttle. To become an independent space station, Spacelab needs little more than a solar array for electrical power and a small rocket engine for maneuvering. So there should be little occasion, or excuse, for the kind of overruns that ballooned the shuttle's cost. If they do occur, help for science may also come from Congress. While there is congressional support for the space station, accord-

ing to surveys by space lobbies, there is even more support for the robot planetary expeditions that have so changed our view of the solar system.

Who benefits from the space station? NASA and the President have emphasized the commercial opportunities for drug and materials processing in weightlessness, but it is too soon to know which, if any, of those processes will turn a profit. The space station is a venture capital investment, in the tradition of the land giveaways of the last century. Judging by the number of young MBAs forming space corporations, the action need not be limited to the multinationals.

There is a danger in being too practical in space. If we are so cautious that we demand an accounting in advance, then our potential is limited by our own lack of imagination. What good is a future that we can predict? In 1971, a spacecraft named Mariner 9 slipped into orbit around Mars and found the planet covered by a ferocious dust storm that had cooled its surface and heated its upper atmosphere. That observation led planetary scientists to investigate what could happen under similiar conditions on earth. They concluded last fall that the smoke from burning cities after a nuclear war could block sunlight, bring about a "nuclear winter," and freeze mankind and perhaps all life right off the earth. This finding, when it sinks in, could help alter our attitudes about war and, maybe, save the race from extinction—if the race were to start behaving rationally. It is hard to think of any more practical benefit. Federal budget cutters might note that a congressional study showing that the technological and economic benefits spawned by NASA expenditures have outweighed their costs by 14 to one.

In other words, space is (in the language of the Eighties) a terrific investment. And it is the space program itself that needs the space station, as an interim payment on bigger dreams. When pioneers leave for the moon, Mars, or beyond, they will ride covered wagons assembled in orbit. Dick Tracy's two-way wrist radios will be fiction no more when there are communications satellites with antennas the size of football fields in geosynchronous orbits—assembled in low orbit and then boosted higher.

Most Americans will never go into space, but their children and children's children will. The space program has become a kind of national monument, our bequest to future generations. It is our acknowledgment that we are wards of the universe, that our cause and our destiny are bigger than ourselves. We have gleaned only a few insignificant structural and chemical details of the mysterious predicament in which we find ourselves: wandering about in individual bodies in a universe of lights, of starry islands all racing apart. We know that those lights in the sky are real places, future theaters in which we may play unknown roles. In this moment, poised between apocalypse and apotheosis, 80 years after we learned to fly, and 5,000 years after we learned to write, the future is still up for grabs.

The world can probably exist without giant communications satellites, without Mars rocks in museums, and without foamed aluminum made in space, but we cannot live without a sense of that future. Only a few great and rich nations have the luxury and duty of creating the future; it is part of the dues of empire. A thousand years from now, when the centers of learning and wealth have shifted elsewhere, perhaps to China or to the moon, we, along with the Soviet Union, will be judged on our stewardship of the earth and of mankind's dreams. Ours is the generation to which it has fallen to take the first steps outward from earth. Perhaps it will be said that, in the brief time allotted to us, we ran as fast and reached as high as we could. *D. O.*

THE AMERICAN JOURNAL OF PSYCHIATRY

The Journey Out and In: Psychiatry and Space Exploration

Patricia Santy, M.D.

Reproduced with permission of the copyright holder from Santy, Patricia, M.D. [311 Yacht Club Way, El Lago, Texas 77586] The Journey out and in: psychiatry and space exploration. The American Journal of Psychiatry, v. 140, May 1983: 519-527.

Although psychiatric issues have in theory always been considered important in space biomedical research, specific research into these issues has been severely limited because of other priorities that were more pertinent to the technological development of space flight capacity. As the technical and physical aspects of space flight become more routine, the psychological issues should take on increasing importance. The author reviews the U.S. and U.S.S.R. research in aerospace medicine that is relevant to psychiatry and suggests ways to expand psychiatry's clinical and research usefulness in future space exploration efforts.

(Am J Psychiatry 140:519–527, 1983)

In our lifetimes we shall probably see the beginnings of the colonization of space. I have no doubt that such colonization would mark the most important series of events in the history of mankind. As a psychiatrist, as well as a scientist, I believe that the ultimate success or failure of this great human endeavor will hinge considerably on many psychiatric factors. Whether man as a living organism can survive the formidable environmental dangers of space seems to have been answered affirmatively by the success of the manned space programs in the United States and the U.S.S.R. Whether man as a psychological entity can survive the transition from life on earth to life (or years) in the space environment remains unknown. A mass of physiological data has been accumulated, but many basic psychological questions remain unanswered.

There are several reasons why the psychiatric questions have not been answered, or even asked in some cases: 1) psychological questions were relatively unimportant in the early phases of the space program because the primary question was whether man could survive at all; 2) the length of time men spent in space and the size of the crews sent on various missions were limited, thereby limiting the type of psychological adjustment necessitated; and 3) the crew's privacy and comfort, which led to the crew's unwillingness to engage in psychological research, were given high priority in the early missions. Astronauts developed understandable suspicion of much of the medical and psychological activities that surrounded the early selection and flights, as described in Tom Wolfe's best seller *The Right Stuff* (1). The clinical psychiatrist, whose medical decisions have traditionally kept pilots grounded, has long been viewed with distrust by military pilots. Berry (2) commented in 1973, "We still know very little about the effects of the space environmental complex on personality and psychic well-being. These aspects of the human could prove to be the factors which limit the duration of space flight."

Now that the United States has entered a new phase in its space program—the shuttle—psychiatry must begin to address some of these crucial questions. In this paper I will review several areas of behavioral and psychophysiological research relating to space flight. I will then discuss models and methods of future psychiatric/psychophysiological research, and, lastly, I will speculate on two issues that relate to psychiatry and future space exploration.

CLINICAL ASPECTS

Astronaut Selection/Crew Selection

The bulk of clinical activity for psychiatry in the U.S. space program has been in the area of preselection aeromedical evaluations. As part of a team of physicians, psychiatrists have had considerable input into the astronaut selection process from the very beginning (2–15). As Kubis and McLaughlin (3) noted with the

first group of seven astronauts, the psychological stability of the candidates was considered of primary importance during the final evaluation process.

In general, situations that require prediction of performance have led investigators to rely on psychiatrists because of their presumed expertise in human behavior. Traditionally, the military aviation psychiatrist has had the power to ground a pilot as "unfit for duty" because of a psychiatric disorder. Because an overt psychiatric disorder is rare among such a select group as astronaut candidates, the psychiatrist's role is most useful for those candidates whose motivations are "pathogenically overdetermined" but who show no current evidence of psychiatric disorder. Personality areas that seemed to relate to potential for successful mission accomplishment have been defined. In particular, the following areas were felt to be of importance in this predictive task: general emotional stability; high motivation and energy level; adequate "self" systems (positive self-concept, sense of adequacy, emotional control); and satisfactory and productive interpersonal relationships. It was felt that the appropriate motivation was for the candidate to be "mission-oriented" (9–11) rather than oriented toward personal achievement. All of these factors were then evaluated by psychiatric interview, psychological tests, and observation of performance under stress. Psychiatric ratings of the candidates for the Mercury mission closely matched the final selection ratings (15).

It is important to note that most of the literature has dealt with the Mercury, Gemini, Apollo, and Skylab astronaut selections. Although psychological tests and psychiatric interviews were conducted on candidates for the more recent Shuttle mission, it is unclear how great a part this information played in the final selection process, but we can assume it was not a trivial one. In addition, the early literature deals with selection among a relatively homogeneous group of individuals: all males, all career military pilots, and few bachelors. With the introduction of the scientist/astronaut candidate later in the Apollo program, a more heterogeneous group of individuals was selected. The motivations and personality of the pilot applicant group may be somewhat different from those of the scientist applicant group. Whether different psychological criteria were, or should be, used for the scientist/astronaut applicant as opposed to the pilot/astronaut applicant would be important to know. (We do know that different physical characteristics were required of the two groups, e.g., vision requirements.) The question of appropriate motivation for space missions, which is possibly an extension of the pilot's professional motivation (15), is not so clear for scientists. According to Perry (9), "As the complexity of motivations increases, so will the chances of their being neurotically overdetermined." There are, however, no "standard" personality types or ready-made guidelines to rely on in assessing psychological capabilities; all such assessments should be part of a more global assessment of each candidate's overall capabilities.

It is unclear what role (if any) psychiatry has played in actual crew selection, i.e., who will be on what mission. Psychiatrists could be extremely useful in this area in evaluating who works well with whom (especially since the number of crew members will increase on later Shuttle missions) and in the application of general group dynamics. Perry (8) has even suggested a psychiatric back-up procedure for every crew that will help deal with emotional problems which may arise in both the crew and their families before, during, and after missions.

In summary, then, the psychiatrist seems to have played an important role in the selection of astronauts. Evaluation of candidates' "psychological fitness" seems valid for selecting astronauts, as does evaluation of candidates' overall "fitness" and the compatibility of crews. The selection process remains an area where psychiatry can expand its clinical usefulness in future space exploration efforts.

Isolation/Confinement

Early in space research the problem of isolation and sensory deprivation was felt to be one of the more serious psychological issues. Numerous studies done on earth-bound isolated individuals and groups, such as submariners (16–21), Antarctic journeyers (17, 18, 22), and volunteers in simulated environments (23–30), reported remarkably consistent findings regarding man's response to isolation. Reported symptoms varied only slightly from study to study, and all studies recorded the following symptoms: boredom, restlessness, anxiety, sleep disturbances, somatic complaints, temporal and spatial disorientation, anger, and (most important), deficits in task performance over time. Furthermore, in studies of isolated groups of men (18, 19, 21), researchers had to take into account such factors as group and social influences, individual and leader roles, and individual personality coping mechanisms. For example, Gunderson (18) and Gunderson and Nelson (19) studied groups in isolated and remote Antarctic stations over several months and followed subjective evaluation by the men of their symptoms. By far the most common complaint was sleep disturbance (reported by 72% of the individuals), followed by depression, headache, irritability, and other somatic complaints. It was noted that all the symptoms increased over time. Even when such symptoms (especially depression and irritability) occur among only a few members of a small, isolated group, they could pose serious survival problems for the rest of the group under certain circumstances; thus it becomes essential to understand the etiology of the problem and to pose some methods for coping with it as a group. (These issues will be discussed further in the section on group interaction.) Consistent in all these group studies was evidence that group compatibility and performance typically declined over prolonged isolation. On the other hand, Earls (20), who studied submariner groups, was struck by "the relative absence of overtly

expressed hostility" on the part of the submariners. This conflict—between the individual's unwillingness to alienate the group (upon which one's individual survival depends) and the increasing and inevitable normal kinds of tension that must remain undischarged (no overt aggression)—can arise in any group situation. Often the unresolved conflict can lead to depression and somatic complaints.

Berry (2) pointed out that sensory deprivation/isolation issues have thus far proved to be nonproblems in space flight (in fact, the opposite, hyperarousal, has more often been the problem). It seems clear, however, that for long-duration, extended space missions manned by individuals with more heterogeneous personality styles, isolation issues will become increasingly relevant and will require further study.

Hyperarousal/Sensory Overload

Instead of men in space experiencing the expected sensory deprivation, it has become obvious that they experience overstimulation or "hyperarousal." Aitken (31) pointed out that such symptoms as insomnia and anorexia, of which many of the astronauts have complained, could be due to a physiologic state of hyperarousal. Normal excitement, intense work schedules, numerous tasks, and the absence of many temporal cues (night versus day) all probably contribute to this state. If the hyperarousal state is prolonged, such long-term effects as perceptual abnormalities, impairment of concentration, depersonalization, muscular incoordination, and overall deterioration of performance may occur. It has been pointed out that several U.S. missions were jeopardized by unusual and unexpected behavior on the part of the crew and that at least one cosmonaut was noted to have unexpected inefficiency in operating his controls and had to be landed early (31). Thus, it appears that sensory overload may be an important factor in short-duration missions, and both sensory overload and sensory deprivation/isolation may be factors in long-duration missions.

Group Interaction

I will look at group interaction issues separately, although some of the problems that arise in this area have already been alluded to in the isolation section. Since the beginning of manned flight, the trend has been to increase the number of persons on each mission. As space vehicles enlarge and personnel roles become more specialized, even larger crews will be necessary to carry out the many research and assigned practical tasks (32). To date, the largest number of men in space working together at one time has been on the Apollo-Soyuz mission, when five people were interacting (three Americans and two Russians) (33). Establishing a large space station for purposes of scientific investigation and support for manned interplanetary missions will require numerous individuals working in a close-knit, efficient team manner. Many of these individuals will have to be highly specialized; they are therefore more likely to come from culturally and scientifically heterogeneous backgrounds. Obviously, psychological compatibility and methods used to determine the selection of the crew will play a large role in the ability of such crews to perform efficiently. The Soviet space program has long recognized this as a problem; to a lesser extent, so has the U.S. program. From the beginning of training, cosmonaut candidates are subjected to the most grueling psychological tests, and the candidates are grouped according to compatibility (34). The Soviets also have the edge in duration studies of groups in space, although, again, it is not as likely that serious problems will arise in small groups of homogeneous cosmonauts who have similar military backgrounds, values, and mission goals.

A new dimension was added to the evaluation of group dynamics in space when the first woman astronaut was selected for the crew of the Challenger. When Valentina Tereshakova, the first woman in space, made her few orbits, she did not have to interact with any male fellow astronauts—she went up alone and was in space for only a short time. Shortly after the United States named its first woman to go up in space, the Soviets sent Svetlana Savitskaya into orbit to rendezvous with fellow cosmonauts in the Soyuz space station. Other than as a publicity stunt and possibly to "scoop" the United States, it is unclear why the Soviets did this, as their thinking on the subject of women in space is not as liberated as one might assume. "Women are more emotional and are upset easier," chief Soviet cosmonaut Lt. General Vladimir Shatalov and veteran cosmonaut Georgy Beregovoi suggested in a recent article (34). Also as far as is known to observers in the West, the U.S.S.R. is not actively training any women to be cosmonauts.

At any rate, the possible repercussions of adding women to space crews are immensely interesting from a psychological standpoint. Thus far, the consequence of adding women to crews has not been dealt with in group studies, which have been with all-male groups. The issue of sexuality, especially on long-duration missions such as an interplanetary one, is not trivial. No matter how well trained the crew is, there is reason to expect that such issues as sexual arousal, tension, and competition are just as likely to occur in space as they are in any earth-bound endeavor, and they present a potential hazard to the accomplishment of mission goals. Having astronauts who are married to each other fly on the same missions is one approach to reducing the issue (currently there are two married couples who are astronaut/mission specialists), but again there is no reason to believe that the same type of tensions may not develop.

One method of approaching the complexity of handling group problems in space could be to train astronauts in simple group dynamics. Perhaps entire crews could participate before their flights in an ongoing group process to help identify and resolve potential trouble areas and to learn problem-solving techniques,

before they arise in the more dangerous space environment. As a practical method, this would also give the astronauts a model for resolving in-flight hostilities and tensions that can lead to group-threatening behaviors and decrease crew performance (35, 36). Such a method would offer useful ways of discharging tension and anger and possibly of alleviating the symptoms of depression and the psychosomatic complaints reported in other isolated groups. Such a technique could be tested out in other groups, such as submariners, in addition to space crews.

It is relevant to note here that in spite of all the concern expressed in the United States early in the space movement about the psychological effects of space on the human organism, according to Bluth (34) the U.S. space program has never made a formal attempt to set up experiments and record behavioral reactions, nor has it used behavioral scientists in its training program. This is one area in which the Soviet Union clearly excels, if only in its willingness to study such problems. It is very clear that psychiatry can make valuable contributions in this area.

Finally, it is important to realize that new situations and environments have always caused alterations in traditional social structures. Men and women in space will be in situations no human beings have ever had to deal with before. Preformed, rigid social structures may severely hinder the processes of psychological and physical adaptation that will be essential to explore the universe. On the other hand, meaningful social and environmental structure is necessary to some degree for individual egos to cope with the space environment. We must avoid letting rigid cultural values and customs, especially in the area of sexual mores, prevent research in this area.

Man-Machine Interactions

Airplane manufacturers have long known the importance of designing efficient man-machine systems for their planes. Faulty design in this area can lead to lethal consequences. After years of research, the size, shape, and even placement of certain dials and instruments are now specified because it was discovered that optimal treatment of these factors increased the efficiency of the pilot's interaction with the airplane and therefore decreased error (37, pp. 128–156, 38–40). The problems of man-machine interaction—from the design of space ships and stations to the layout of systems within the space vessel—seem especially relevant for psychiatric investigation. Issues of habitability become extremely important in longer-duration space endeavors (41). Attention to environmental detail may be an important factor in helping astronaut crews deal with stress during long-duration missions.

Jones (41) discussed nine aspects of habitability that were first compiled by Johnson (42): 1) environment (including atmosphere, temperature, lighting, and radiation levels); 2) architecture (how the living space is arranged); 3) mobility, restraints, and equipment handling; 4) food (i.e., preparation and storage); 5) clothing; 6) personal hygiene (body waste collection, grooming); 7) housekeeping (refuse, cleaning, laundering); 8) communication (intravehicular only); and 9) off-duty activity provisions (exercise and entertainment). Other issues that I believe will be important on long-duration missions are continued communication between the crew and earth; allocation of space for individual mementos (e.g. pictures and items with sentimental attachment); time for off-duty creative activities, such as painting, writing, or gardening; and the option of being alone, i.e., space designed to allow individuals to be by themselves.

The National Aeronautics and Space Administration has long recognized the importance of habitability in determining astronaut morale. Food items, for example, are selected to meet the tastes of individual astronauts. Music is used to boost morale on the space missions (wake-up calls played by Mission Control are often selections of the crew's favorite music or humorous sketches). Humor plays an important part in keeping tensions low. For example, in submarines it has long been noted that the number of practical jokes tends to increase during the voyage and seems directly related to the build-up of tension. As mankind's efforts in space expand, these habitability factors are bound to become increasingly important. For instance, the psychological needs of the shuttle's passengers have been kept in mind during the design of its environment. The Soviets have also recognized their passengers' needs, and during their long-duration missions, cosmonauts reported much satisfaction with their gardening attempts in space—as both a recreational pursuit and as a practical solution to the problem of obtaining food in space. In the popular TV series *Star Trek*, the *USS Enterprise* offered its crew a gymnasium and a botanical garden with plants from the home planet, as well as an interfaith chapel.

Other aspects of man-machine interaction should also be studied. Advances in computer technology have major implications for the men and women whose lives may depend on the appropriate functioning of such machines. In the science fiction film *2001: A Space Odyssey*, a paranoid delusional computer began to kill off its human crew. But computers with personality are no longer just science fiction. As computers become more sophisticated (more "human"), human reaction to computers may become increasingly less predictable. Along these lines, a recent article in the *New York Times* (May 2, 1982) told about a factory worker in England who "fell in love" with the machine he operated and who became upset when the company transferred him away from it. In large part, the interaction between man and machine is what will make space exploration possible. The input of psychiatry into this area can obviously be of great value. For example, studies on the psychological response of humans to computers or to machines in general would potentially be a useful research area. In addition, studies that look at individuals whose lives are depen-

dent on machines (e.g., hemodialysis machines and pacemakers) and these individuals' interaction with and feelings toward the machines would be relevant. Studies on the variability of stress and response in different habitats would be extremely important in designing future space dwellings.

The goal of studying man-machine interactions is to maximize the ability of man to work and live in the space environment. Many of the factors that now impede our achieving this goal will ultimately be reduced to an understanding of the psychological issues in man-machine interactions.

PSYCHOPHYSIOLOGICAL STUDIES

Response to Stress

Physiological variables have been monitored since the early days of manned flight. The traditional vital signs (heart rate, blood pressure, respiration rate, and temperature) were monitored in every manned flight because there was concern as to man's physiological capacity to deal with the physical aspects of space flight—weightlessness, in particular (37, pp. 50–92, 43–45). Measuring physiologic responses to stress was a part of the selection procedure and provided baselines for comparison in flight. Several important facts soon became apparent: 1) there is a considerable difference between laboratory stress and operational stress; 2) individual physiological response to stressful situations varies considerably; 3) physiologic response is not predictive, particularly of actual (behavioral) response, although it is useful in understanding and monitoring an organism's adaptation to the stress; and 4) no single physiological parameter can adequately reflect how the organism is coping with the stress, i.e., the homeostatic balance of an individual (15, 44).

As Rose (46) pointed out, in general the "*psychological* relevance of the stimulus rather than the particular physical stressors to which they were exposed has the most effect on the physiological response." Individual physiological response to stress has been measured in astronauts by breaking down the stress into four areas: 1) rest (normal, baseline), 2) anticipation, 3) stress, and 4) recovery (47). The study of the anticipation phase of stress application proved extremely useful in differentiating the emotional component aspect of the stress. In many situations the astronauts were found to have a greater physiological response during this phase than during the actual flight. This again points to the fact that individual response will vary greatly and will depend considerably on the individual's personal history, which may contribute a high degree of emotional loading to the response.

In addition to measuring the astronauts' vital signs, investigators of the early Mercury and Gemini missions determined the astronauts' levels of catecholamines (epinephrine, norepinephrine, and their metabolites) and 17-hydroxycorticosteroids excreted in urine. Epinephrine and norepinephrine are extremely sensitive measures for a wide variety of emotional stimuli. Epinephrine secretion is felt to be associated with situations characterized by novelty and unpredictability and seems to reflect the anxiety of a situation. When the situation is mastered, levels of epinephrine fall. On the other hand, norepinephrine secretion seems to reflect the amount of "attention-demandingness" or effort associated with a given task or the physical effort (46, 48–57). Technical problems abound in the measurement of urinary excretion of the catecholamines, and wide individual variability is found. Other parameters measured in the Apollo and Skylab missions included plasma cortisol and ACTH, as well as 24-hour urinary cortisol, growth hormone, and thyroid function (including free T_4). As one might expect, the astronauts' urinary epinephrine levels stayed relatively stable while they were in flight but increased before and after flight. Norepinephrine was more variable than epinephrine, but generally it seemed to increase at times during and after the mission. The astronauts' plasma cortisol levels increased substantially, and ACTH levels decreased throughout the Apollo and Skylab missions. The astronauts' 24-hour urinary cortisol levels increased substantially on all missions. Levels of free T_4 were found to be increased after the flight, and there was a modest increase in thyrotropin levels during flight. Growth hormone levels varied, but there was a noticeable increase in these levels during the first days of each mission and the first few days after recovery. All variables returned to baseline shortly after completion of each mission, and some returned to baseline during the mission, suggesting that adequate adaptation to the stress had occurred. The general rule seems to be that endocrine responses in flight extinguish as adaptation occurs (58–67).

Coping responses, or how individuals avoid being stressed when exposed to threatening environmental situations, are of special interest to the psychiatrist. Researchers (68) found that individual psychological defenses, such as isolation and denial, resulted in subjects' low cortisol secretion before a stressful event compared with subjects who were overtly distressed before the event. Thus, a defense may be effective physiologically but maladaptive psychologically, and it becomes an even greater threat to the organism. For example, women who had breast tumor biopsies and who denied the situation had low cortisol levels; however, because these women had waited much longer before coming to medical attention than women who feared the situation and immediately sought help, they put their lives at greater risk. In the same way, defensive structures in future space explorers may be vitally important; they may be more important than the explorers' physiologic response to stress. What seems to be missing from all the physiological data that have been accumulated are the concomitant behavioral correlates that would give the data more meaning.

The administrators of the Soviet space program have

always rated highly the behavioral aspects of space flight, and they have incorporated behavioral ideas into the cosmonauts' training program for the purpose of increasing individual stress tolerance. Reportedly, they put their cosmonauts through "live" hazardous environmental tasks (i.e., survival in a hostile climate) as part of training. Their purpose is to train cosmonauts to adapt psychologically to highly stressful situations. In fact, their entire training approach is behavioral and based on the so-called information theory of emotions (69, 70). This theory holds that the degree of emotional stress (E) is related to motivation (M) and information (I) by the following formula:

$$E = -M\,(I_n - I_r)$$

where I_n represents the information the subject needs in order to successfully negotiate a difficulty, and I_r is the amount of information the subject actually has or is able to receive. Although this is clearly a simplistic way of evaluating such complex phenomena, it has been surprisingly useful to the Soviets. They have, in fact, focused almost exclusively on the term $I_n - I_r$; they have tried to cognitively prepare their cosmonauts for every conceivable stress, thereby increasing I_r and reducing the term to zero (no emotional stress experienced) or to a negative number (only positive emotion experienced). Motivation, however, is also an important factor and deserves more recognition in research efforts. The M term includes such factors as defense structure, personality type, and coping mechanisms. Furthermore, because it seems likely that space will provide the human organism with environments and situations never before encountered in mankind's experience, the $I_n - I_r$ term may never completely approach zero, and the M term may need clarification and expansion.

Wherry (71) suggested a model for studying psychological stress, and Sells (32) has evaluated various terrestrial systems that could be used to study the stress and coping aspects of space flight. The shuttle offers a remarkable opportunity for behavioral scientists to do studies of men and women in actual space conditions.

Biological Rhythms

Psychophysiologic aspects of the sleep/wakefulness cycle, or circadian cycle, seem to be of particular importance in space flight (72, 73). Many physiological markers are rhythmic and affected by the physical cycle of day and night. (These include EEG, body temperature, hormonal variations, and immune variations.) The normal physiological time requirement for sleep appears to be about 8 of every 24 hours. Numerous studies have shown that attempts to ignore the need for sleep results in neurotic and possibly psychotic disturbances, including hallucinations and delusions. Air travelers moving through different time zones have aptly demonstrated the difficulty encountered in trying to "reset" this biological clock (74). It is possible, however, to change these rhythms over time (it usually takes 7–14 days, which is probably due to the slowness of response of such biochemical indices as cortisol levels) (75). Biological rhythms are reset when one changes from day to night work or even from a 24-hour work cycle to a 12-hour one. The desynchronization that occurs during such times may play a role in sleep disturbances, dysphoria, mood shifts, and gastrointestinal disturbances. All these symptoms have been reported in people during the biological readjusting or "resynchronization" (76, 77).

Our understanding of the underlying mechanisms of biological rhythms is still limited, but environmental cues seem to be an important factor in the cycling process (e.g., dark and light). In space, there are no environmental cues because the rotation of the earth and its day/night cycle are not observable. Natural time references, therefore, are absent. Studies with submariners indicate that, if clocks remain unchanged in the submarine, the men's diurnal cycles will remain undisturbed by the lack of outside cues. Likewise, it has been found that astronauts tend to stay on the same rhythm as their site of origin (72, 78). Obviously, earth time zones have little meaning for the orbiting space ship, as it passes through each zone in only a few minutes. Work/rest periods for astronauts will be dependent on their internal biological clocks. Studies in closed-cabin environments show that, without environmental cues, 5 hours of sleep and occasional catnaps during the work day seem to be sufficient for the inhabitants. Fatigue and increasing proneness to error were noted when this cycle was disturbed (78).

In recent years there has been an increasing emphasis on biological rhythms and their importance in psychiatry (79–81). The reality of time is part of the structure of the human organism. In addition to performance studies (79), which show that specific performance tasks seem to peak at different times depending on the skill required, studies of desynchronization have found that this factor plays a role in the etiology of depression, medical illness, and an individual's response to stress.

Although the human organism has proved to be extremely adaptable and capable of resynchronization over a period of time, it is unknown how far this adaptability extends. For example, will humans be able to colonize planets in other star systems—or even travel to those planets—if the biological rhythms established in our course of phylogeny on this planet are not compatible with voyages and life outside the sphere of terrestrial influence? Strughold (72) commented, "The physiological clock, manifested in terrestrial circadian rhythmicity, will play an important role in health and performance in man's conquest of space. . . . Its study under non-terrestrial cosmic conditions may shed some light upon the true nature of the biorhythmic phenomenon."

Psychophysiological Monitoring of Man in Space

From a practical point of view, the physiological monitoring of man in space is a great deal easier than psychological monitoring. Future space flights will continue to provide scientists with physiological data in areas pertinent to psychiatry. Data from studies of the hormonal and fluid/electrolyte status of astronauts will be essential to acquire on long-duration missions. EEG telemetry in the Gemini and Apollo flights proved to be a useful and practical method of monitoring sleep/alertness states (82–89). All these data are helpful in planning long-duration missions (89). There are many methods available for analyzing the physiological and biochemical responses of man to the space environment; however, behaviorally, there is a relative lack of pertinent research planning and information, especially information that can help to integrate the physiological data with actual behavioral changes. The psychiatrist is specially trained to integrate behavioral and physiological aspects of the human organism. As missions expand in length of time and number of crew, psychiatry's mission support responsibilities will need to expand into ongoing projects and in-flight support and research. In other sections of this paper it has been suggested that psychiatry can offer substantial expertise in many aspects of medical support for space flight. In addition, the psychological monitoring of humans in space requires that behavioral scientists should be part of the crew in order to conduct continuing research into man's psychological adaptation to space exploration. Astronauts have routinely reported on subjective experiences and have kept detailed logs during the missions, but these data must be considered only the beginning of behavioral research. Trained observers and researchers might provide even more reliable information and insights. The psychiatrist does not have to be considered a threat to the rest of the crew or as someone "invading the privacy" of crew members. If psychiatrists and behavioral scientists can be integrated into the structure of the crew in a manner similar to other medical professionals, an understanding by the rest of the space team of what psychiatry can offer will be obvious, and behavioral research will then come to be as acceptable as any of the other types of research that are carried out in space.

One possibility is to involve psychologically trained mission specialists in making more detailed and ongoing recordings of the astronauts' emotional responses to various positive and negative stresses in space (e.g., contacts with family members, recreational activities, response to unexpected problems). To further amplify the astronauts' responses, brief psychological tests could be administered at specific times. As part of the crew, such mission specialists may provide valuable data about crew interaction and interpersonal conflict resolution in the space environment, as well as valuable insight into man's psychological adaptation to the hostile environment of space.

SPECULATIVE ASPECTS

There may be many other opportunities for psychiatric input into the space exploration effort over the next 25 or more years. At the risk of sounding like the author of a science fiction story, I would like to suggest some areas of research that are purely speculative at this point but in which psychiatry may play an important role. The first area is an extraterrestrial psychology. A considerable amount of money has been spent and numerous volumes written by reputable scientists on the search for extraterrestrial intelligence (SETI). The field of exobiology has existed for many years and has grown considerably since it was first speculated that life in the universe may be based on an element other than carbon, e.g., silicon. Only science fiction writers have made attempts to speculate on the differing psychologies that such biologically alien beings might have. If these scientists are correct and the probability is high that intelligent life outside of our own exists, the problem of communicating with and understanding such beings may become imperative. The scope of the problem is tremendous, not only in speculating how the different biology has affected the alien psychological development (which would certainly lead to a better understanding of the interaction among biology, psychology, and the environment in living organisms), but also in studying human response to the potentially infinite number of forms such life might take.

A second and much more relevant area that also lies within psychiatry's realm is in understanding the "psychological evolution" of the human species. Niederland has touched on this fascinating problem in his writing on psychogeography (90–93). The problem involves nothing less than the concept of separation/individuation of our species from this planet, Mother Earth. What symbolism and fantasies lead individuals to go beyond their present horizons? Space exploration and the colonization of space by humankind offers a unique opportunity to study the motivation of our species as a whole. During the last great expansion of mankind, the westward movement (first to the New World, then within the New World to the American West, and now to space), psychiatry was a newly emerging discipline and perhaps was not yet ready to tackle such a task. Space exploration is, after all, the natural extension of an ongoing process that has enveloped mankind ever since evolution began on our planet.

There are many areas in which the clinical and research expertise of psychiatry may prove essential for the success of a manned space effort. As Perry (15) noted in 1967, "It is as if the absence of reports concerning *man* (as a psychological entity) were a product of denial in the psychoanalytic sense of the term. If this be true, of course, it would only serve to underscore the importance for the place which psychiatry may eventually have in support of man's progressive explorations of space."

INTERNATIONAL EARTH-ORBITAL RESEARCH HABITATS

Toward Men Permanently in Space

Before the end of this century, thousands of people from around the world can have lived and worked together in an Earth-orbital research "proto-colony" of several hundred inhabitants

Reproduced from Salkeld, Robert. Toward men permanently in space. Astronautics & aeronautics, v. 17, Oct. 1979: 60-69 with permission of the copyright holder Aerospace America.

The Apollo program proved that people can perform effectively for many days in space, and its descendent project, Skylab, extended this demonstration to nearly three months. Last year the Russians surpassed Skylab, and they appear committed with their Salyut orbital station to establishing the permanent presence of people in space.[1] Historical data and trends in F-1 show that the USSR leads the world in total person-years in space, can continue to do so for at least a decade, and that by 1990 we may expect to see 50-100 people living and working in space continuously.

So it appears that permanent human occupancy will be a next major milestone in the conquest of space. The U.S./European Shuttle-Spacelab cooperative effort moves in this direction, though slower-paced than the Soviet work. Lower-cost space transportation needed to support permanent occupancy has been identified and its technologies are being pursued in both the U.S. and USSR.[2-4]

Much of the future space population will be engaged in extensions of research and technology already begun in connection with Skylab, Salyut, Shuttle, Spacelab and other programs. Knowledge and knowhow from developments in space can benefit all peoples of the world. Many of these activities can be conducted most effectively on a cooperative integrated basis. *This suggests that all might gain greatly from an international Earth-orbital habitat for research and technology.*

An international spirit has always been part of the move into space and it is growing. From modern beginnings in the writings of Poe and Verne through setting of the technical base by Tsiolkowsky, Goddard, Esnault-Pelterie, and Oberth, the intellectual roots of space exploration have been diverse. The same is true of practical milestones. Goddard launched the first liquid rocket in 1926, the V-2 flew in Germany in 1942, the first Earth-satellite and first spacemen lifted off from the Soviet Union in 1957 and 1961, respectively, and the first men, Americans, walked the Moon in 1969. Direct USSR-U.S. cooperation in manned space operations began with the Apollo-Soyuz Test Project (ASTP) in 1976. Salyut has flown with international crews, as will Shuttle and Spacelab.

The International Astronautical Federation (IAF) was formed in 1950, Intelsat in 1964, and the European Space Agency (ESA) in 1975. At least a dozen other international space organizations,

governmental and commercial, now exist. As of September 1977, 146 nations reported space-related activities, 126 non-launcher nations had 354 international space memberships, 35 had cooperative space programs, and 21 had 78 bilateral programs.[5] As of 1980, seven powers will own orbital launch systems and 21 will have satellites.

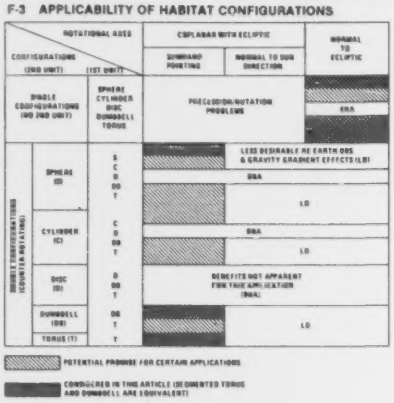
Many times astronautical concepts and commitments have crossed oceans and borders. After coming to the U.S., Wernher von Braun with members of his German team and leaders of the American scientific community jointly formulated in 1952 a forward-looking space program which included a permanent Earth-orbital station (F-2).[6] Serving as a platform for scientific observations of Earth and the cosmos, von Braun's station would rotate at 2.7 rpm to produce 0.35 *g*. It would provide submarine-like living accommodations for about 80 people. This concept remains technically feasible except that the Van Allen radiation belts subsequently discovered require an orbital altitude less than about 600 km, and the station would need a shielded "storm cellar" to protect permanent inhabitants against radiations from occasional solar flares.

Since von Braun's proposal, many concepts for permanent orbital stations have been studied quantitatively by government and industry, most of them modularized assemblies designed for no more than a few tens of people. But on a qualitative basis, Romick in 1956 suggested the concept of an Earth-orbital "city" of 20,000 inhabitants with a rotating residential disc at one end, constructed around a core formed of used rocket fuselages.[7] Also qualitatively, in 1967 Ehricke proposed an Earth-orbital "resort hotel" for 1200 people incorporating large zero- and partial-gravity "dynariums" for recreation and sports.[8] In 1974, jumping to a more ambitious scale, O'Neill proposed "colonies" constructed at lunar distances from lunar materials, and accommodating 10,000 to several hundred thousand people, an idea which has now received considerable study.[9-15] In support of O'Neill's work, Driggers explored a 2000-person "construction shack" at lunar distance.[10]

Despite this stimulating work, near-Earth habitats in the size range of, say, 50 to 10,000 people, have received little systematic quantitative study. (I have suggested a near-Earth "protocolony and technology station" for several hundred people, and a related design point for a 1000-person prototype colony has been explored in some detail.[16,15]) For reasons developed in this article, I believe that an international orbital research habitat should be somewhere in this size range; and the

F-2 Von Braun proposed a permanent toroidal Earth-orbital space station in 1952. Eighty persons would live in the 76-m-diam station in synchronous orbit at 1730-km altitude. Illustration by Chesley Bonestell in *Colliers*.[5]

F-3 APPLICABILITY OF HABITAT CONFIGURATIONS



T-1 HABITATS CONSIDERED
Torus segmented at smallest population to maintain minor radius at no less than 2.5 m.

CONFIGURATIONS / PARAMETERS		TORUS						SPHERE					
		SINGLE			DOUBLE			SINGLE			DOUBLE		
		RIM	TOTAL		RIM	TOTAL							
POPULATION		10	25	50	25	50	100	50	150	500	100	300	1,000
ILLUMINATION		ELECTRICAL						DAYLIGHT					
ROTATION	AXES	NORMAL TO ECLIPTIC			SUNWARD			NORMAL TO ECLIPTIC			SUNWARD		
	PSEUDOGRAVITY, g (MAX AT 3 RPM)	0.5	0.9	1.0	0.5	0.9	1.0	0.25	0.5	1.0	0.25	0.5	1.0
	RADIUS, m	47.5/2.5		95/5	47.5/2.5		95/5	25	50	100	25	50	100

article explores what such a habitat might be like, how long it might take to construct, and how much it might cost.

Each habitat would include the means for Earth observation (resources, environment, weather, etc.), cosmological research, materials and products research (including pharmaceutical, biomedical, agricultural and ecological studies), and basic technology development for advanced space systems, including information handling, large structures, and energy systems.

Habitat design assumed the following characteristics: population, 10 to 1000; construction, integral and done in orbit (aluminum shell with 218.7 MPa tensile strength); orbit, Sun-synchronous at 550-km altitude (est. ΔV required for orbit maintenance, 20 m/sec/yr); photovoltaic power (fuel cells for eclipse/reserve); no extensive or complex windows.

Internal environments include pseudogravity at 3-rpm max (Coriolis limit), 0.5 atmosphere (50% O_2, 50% N_2), radiation protection by solar-flare shelter providing 5 t/m^2 protection (adequate against the largest recorded solar flare, of Feb 23, 1956), area and power adequate for partly to fully closed ecoculture depending on habitat size, and soil 0.3 m deep over about 40% of habitable area.

Programming and scheduling are based on a "surprise-free" environment with no extraordinary drivers, and operational logistics are based on the conservative assumption of an open ecosystem with partial oxygen recovery.

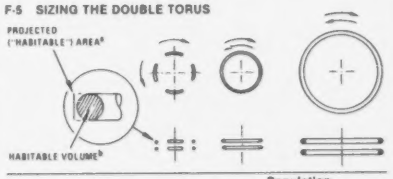
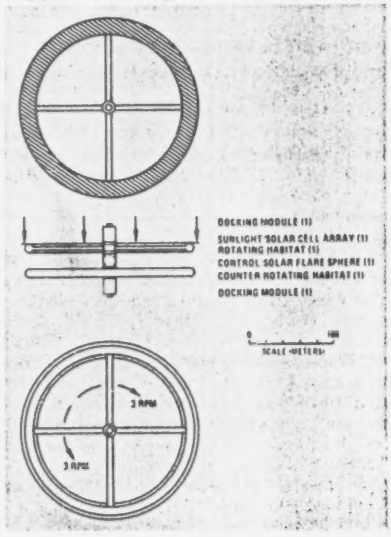
F-5 SIZING THE DOUBLE TORUS



Characteristic	Population 20	50	100
Torus radii, m	47.5/2.5	47.5/2.5	95/5
Pseudogravity, *g*	≤0.5	≤0.5	≤1.0
Habitable area, m^2/person			
Required from F-4	37	61	110
Available	38	62	123
Habitable volume, m^3/person			
Required from F-4	78	198	580
Available	146	234	938

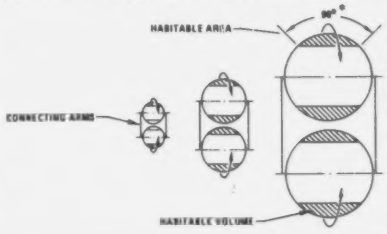
F-6 DOUBLE TORUS HABITAT
For population of 100, ≤ 1.0*g*, rotation axis pointing Sunward.



The habitat directly serves research and technology studies only, and not large space operations such as information-handling platforms, solar-power satellites, materials processing factories, or military activities. Only in this way can such an international cooperative enterprise be as free as possible from political, economic, and military obstacles.

F-3 presents a matrix of possible habitat configurations. T-1 and F-3 describe toroids and

F-7 SIZING OF DOUBLE SPHERE
Ninety deg selected as balance between use of space livability plus reasonable *g* range. At 90° minimum *g* is 0.7 maximum *g*.



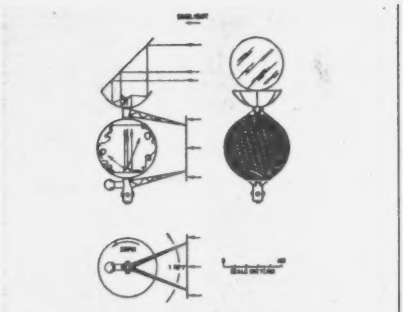
Characteristic	Population 100	300	1000
Sphere radius, m	25	50	100
Pseudogravity, *g*	≤0.25	≤0.5	≤1.0
Habitable area, m^2 /person			
Required from F-4	110	145	172
Available	111	148	178
Habitable volume, m^3/person			
Required from F-4	580	1196	1800
Available	463	1236	2966

spheres selected for consideration. F-4 gives habitat area, volume, and power requirements. The curves in F-4 are plotted from case-by-case analyses in which requirements were broken down into "urban" and "agricultural" elements (as in Ref. 12, 13, and 15) plus a "research" element. Eclipse and reserve power requirements were set to permit uninterrupted research at full power should photovoltaic power be lost.

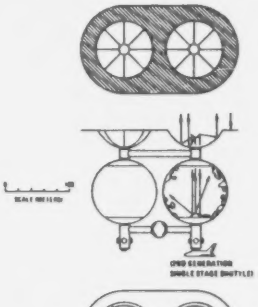
Sizing and design for toroidal configurations are shown in F-5 and F-6, and for spherical configurations in F-7, F-8 and F-9. F-10 gives habitat mass trends as a function of population. The curves in F-10 are plotted from individual mass estimates aggregated from a 22-item mass breakdown for each of the twelve point designs considered. The mass estimates are based on relationships and assumptions extracted from Ref. 10-15.

T-2 presents a possible evolutionary sequence of Earth-to-orbit transportation concepts and their costs. Data from T-2 and F-10 are combined in F-11 to show which vehicle concepts provide lowest transportation cost as a function of habitat population. A growth version of the Space Shuttle would suit populations between about 15 and 150 people. Between 150 and 750 people requires a second-generation "priority" Shuttle. Above 750 people calls for a second-generation "heavy" Shuttle.

For three toroidal and three spherical point designs, habitat program costs were estimated year by year according to a 16-item breakdown, and



F-8 Single-sphere habitat would house 150 people at 0.5 *g* or less. Solar array would cover the large disc at right. Nonrotating cylinder at bottom would have zero-*g* labs and docking and entry module. Small sphere at bottom would serve as control room and shelter during solar flares.



F-9 Counter rotating double sphere habitat would house 300 persons at 0.5 *g* or less. Solar array would cover shaded area.

ROBERT SALKELD (AF), consults to industrial and government organizations in aerospace and military planning, has held management positions at System Development Corp., United Aircraft, the Aerospace Corp., and Space Technology Laboratories, and took part in early studies of reusable launch vehicles and spacecraft, space stations and advanced strategic concepts. As a consultant he originated the mixed-mode propulsion concept for reusable single-stage shuttles and tugs. At STL, he worked on the Pioneer I deep-space probe. His book, *War and Space* (Prentice-Hall, 1970), examines military and political aspects of space.

collected into six major cost categories. Those six were then profiled as a function of time (F-12). Habitat cost estimates were based mainly on historical and projected cost data for large NASA programs and only partly on other costing schemes,[10,15] which I think to be generally over-optimistic. (T-2 shows the basis for transportation costs.)

Total costs, including ten years of operations, range from $6.8 billion for a 10-person habitat to $46.2 billion for a 1000-person facility. Peak-year funding varies from $1.5 billion for 10 people to $4.5 billion for 1000 people.

Development and construction time ranges from eight years for 10 people to 17 for 1000 people. Construction times assume assembly productivity of 450 t/man-year (three-shift basis).[12] The 300-person double-sphere habitat and a construction time of five years requires a construction crew of 10 persons supported in a modest space station (included in the "theoretical first unit" costs).

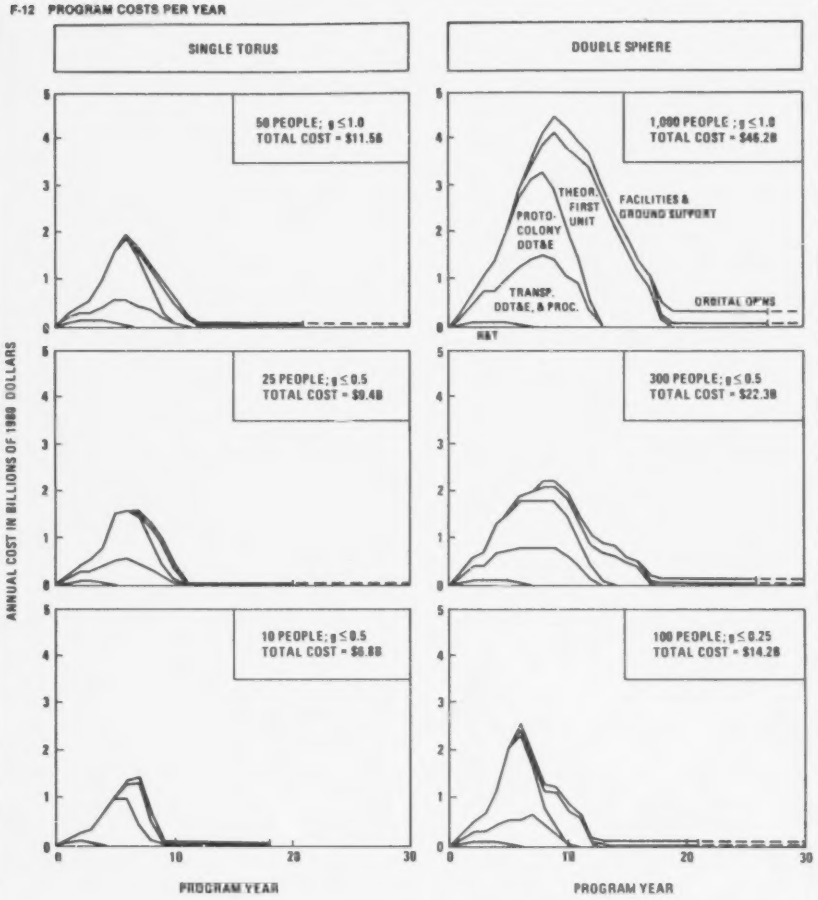
These cost trends are summarized in F-13 together with program cost per person, assuming each person occupies the habitat for a six-month period. Thus, for a 300-person colony over a ten-year period, 6000 of the world's researchers and their families could conduct studies in and about the orbital habitat at a per capita cost of $3.7 million. As indices of economic preferability, F-3 shows products of the curves for program cost, cost per person, and peak-year funding. The resulting "bucket curves" suggest that the cost-optimum population of an Earth-orbital research habitat may be between 200 and 500 people.

Design, development, construction, and operation of such a habitat present challenges in many fields of engineering and biology, including fabrication techniques, ecosystem and thermal control, power and illumination distribution, health and medical management, maintenance, repair, safety and emergency operations. After serious scrutiny by the technical community in recent years,[7-18] it appears that essentially all of these challenges can be mastered with currently understood technology. Salyut, Shuttle, Spacelab and their growth versions will provide the basic knowhow to undertake development of permanent orbital habitats.

Decision to pursue such a project would be bold indeed. As with any forward-looking enterprise, there are many arguments for caution and rejection—cost, risk, time, fears of "technology giveaway," and so on. Politically, it might develop that the only practical way to undertake the program would be on a national rather than international basis.

But the spirit in which such a large and important step is taken will shape the course of space de-

F-12 PROGRAM COSTS PER YEAR



velopments. We accept that many phases of space activity will be competitive politically, economically, and militarily. I believe that those aspects should be balanced by a major undertaking on a truly cooperative basis, that the nations should move toward permanent space occupancy and human migration into space as a common effort of, by, and for the whole world.

INTERNATIONAL REACTION

Astronautics & Aeronautics *solicited the responses of space figures around the world to Salkeld's view of an occupied space platform by 1990 as the next major milestone in the conquest of space and an inspiration for international cooperation. Of the four who replied—from Japan, Europe, and the U.S.—three back a large space station. Gerard O'Neill would rather head in a different direction. George Low's comments should correct the mistaken impression* A/A *gave in its April issue that he advocates an early manned mission to Mars. A quote lifted out of context appeared on page 11.*

USE OF NONTERRESTRIAL MATERIALS A BETTER GOAL

The notion that an international low-orbital space station, a kind of upgraded Apollo-Soyuz, could become a high-priority project merits discussion. It seems, though, quite far from the mainstream of interest in advanced space programs—automated observation and communications satellites, development of large extended space structures, and the controversial satellite power station. The use of nonterrestrial materials for producing structures in space, although only in the study and planning phase and itself controversial, certainly has far higher possible impact on future programs than an international space station shorn of the research activities that have highest potential for future growth.

Very few researchers are working on space-station or space-habitat design at this time, so it is good that Salkeld is contributing effort to it. I have some reservations about his conclusions. *Space-Based Manufacturing from Nonterrestrial Materials* (*Ed.*—Edited by O'Neill.),

Vol. 57 in AIAA's Progress Series, is the only reviewed material published so far bearing on space-habitat design. It is well worth studying but does not appear on Salkeld's reference list.

The most detailed studies so far indicate that the lowest-cost form of 1-*g* space station would be two or more surplus Shuttle external tanks tethered together by long steel cables. Rotation would give them a pseudogravity along the tank axes, and would allow decoupling entirely the area and volume of the station/habitat from its gravity and rotation speed. Salkeld's designs lack that decoupling, and are rather inefficient in consequence. For space habitats fabricated rather than converted, the "Crystal Palace" is the strongest and best shielded for its mass. Spheres at 1 *g* become rather efficient and attractive above 100-m radius if the volumes near their 0-*g* axes are used efficiently, and if natural interior sunlight is taken as an important positive quality. Below 100-m radius the rotation rates required for 1 *g* would disorient some people. Toroidal designs that seemed reasonable in the 1950s hold less attraction now that we know how much shielding a habitat in orbit must have.

The first months of 1979 have seen considerable achievement in advanced space programs, but also a severe threat. Excellent studies by Convair and MIT have confirmed the economic utility of using lunar materials even from a very early stage in any large-scale program of space construction. Those studies concluded that 90-96% of the mass, of, for example, a power satellite could be obtained from common lunar elements. The Lunar and Planetary Institute of Houston has concluded in another fine NASA-supported study that a space-based plant using lunar materials could process 50-100 times its own mass in a year. Complementing these studies and in cooperation with them, a series of workshops coordinated by Princeton has explored scenarios of minimal scale, cost, and innovation aimed at achieving as soon as possible the productive use of nonterrestrial materials.

Though it is too early to state final conclusions, I believe the evidence so far presented shows that the first productive use of nonterrestrial materials could be obtained for a capital cost lower than that of Shuttle development for producing a few thousand tons per year of finished products. That direction of research particularly excites me because of its practicality and immediacy. Later, 100,000 tons—90% of an SPS—per year from lunar materials could be reached without a rocket vehicle beyond the Shuttle. The one development crucial to it appears to be learning how to process lunar soil chemically. A small-scale bench-chemistry effort to establish that technology seems to be to be of the very highest priority.

Unfortunately, in the continuing reorganization that has occupied much of the time and effort of NASA during the past two years, the program office that funded these innovative studies vanished early in 1979. With it went the modest but highly productive study program on using nonterrestrial materials, a program that in 1978 absorbed about 10^{-4} of the NASA budget or 10^{-6} of the federal budget.

Forces within the government interact complexly at this time. Senator Harrison Williams's High Frontier Feasibility Act signed into law in 1978 requires a study by the National Science Foundation of "the feasibility of transmitting solar energy to Earth by using orbital structures manufactured from lunar or asteroidal materials." That study is just now being organized. The Department of Energy's investigation of satellite power has concentrated, quite wisely, on environmental questions, and to the surprise of many has so far discovered no unacceptable effects. DOE recognizes the need to broaden its study and to consider a wider range of routes to satellite power. Congress continues its pressure for a stronger space program, and in part because of concerns over a possible arms race in space, keeps on funding the Shuttle overrun. That is important. The Shuttle is the only really new vehicle—not counting vehicles that would use existing engines—that a program for using nonterrestrial materials would need.

Gerard K. O'Neill

FITS JAPAN'S SPACE POLICY

I am a Commissioner of Space Activities on the Commission of Japan, which is responsible for making the space policy of the Japanese government. This commission issued the "Outline of Japan's Space Development Policy" in March of last year. In this development, we emphasized the importance of international cooperation as one of the three basic principles of our space development policy. Japan is now developing various kinds of scientific and application satellites and launch vehicles for its own space programs. Also Japan plans to use the Space Shuttle for scientific observations and space processing experiments. The document says, "With the technological resources gained from these activities, Japan will play a suitable role by participating actively in such programs as the second phase of the Space Shuttle and a large-scale space station for the sake of efficient space development of the world."

I have read Salkelds' article with great interest. I personally feel very strongly that his idea will just fit our space policy. I hope his article will draw the attention of many people of various countries so that his idea will be supported by the international space community. I am sure Japan would join a preliminary study group of the international community from the beginning, if it were set up.

Shigebumi Saito

CENTRAL TO LEADERSHIP IN SPACE

I propose that the United States establish a national purpose, as follows: "It shall be the policy of the United States to regain a position of world leadership through strength in technology; to use technology development as a significant force in world politics; and to recognize dependence on technology as a major contributor to a healthy economy."

Clear goals, objectives, specific programs, and timetables must follow such a first step. As one of those goals I suggest leadership in space.

Why leadership in space? Here are some reasons:

- The exploration of space appeals to the human drive for adventure and the human thirst for knowledge. It inspires our younger generations, and evokes the spirit of all people of all ages. It provides the spark for optimism about the future.
- The use of space has become indispensable in today's world. Communications and weather satellites provide essential services. Environmental and resources satellites are beginning to furnish accurate reports on global Earth and ocean resources and conditions. Accurate agricultural forecasts lie just around the corner.
- Space technology sets the pace for other technological developments. Our economy is driven by productivity. Productivity is tied directly to technological advances.

And space technology is at the cutting edge of all technology.

• Space projects offer opportunities for international policy initiatives. Options exist for cooperation or for competition with advanced or developing nations.

• Space projects demand an advanced and innovative aerospace industry—an industry essential to our national defense. In time of peace, space projects can help maintain the readiness of that industry by involving it in productive civilian efforts.

Many opportunities exist for leadership in space. The constraints today are largely economic and not technical. The potential for returns, when measured in terms of a national purpose, is great. We will soon be in a unique position to undertake a major new initiative in space by making use of the essentially unlimited access that the Space Shuttle will offer. But the Shuttle alone is only a tool—a key that will open the doors to other opportunities.

A program for space leadership should result in new services from space, and an exciting program of space exploration. There is no alternative as a central element of the program to a permanent manned orbital platform leading to continuous human beneficial occupancy of space.

A leadership program, by definition, involves men and women in space. We all know that we are kidding ourselves if we say anything other than that.

In manned space exploration, the next logical step is a flight to Mars. Such a program is beyond our current means. Scientific exploration will, for the time being, be carried out with unmanned vehicles except for observations made from Earth orbit.

A space platform fulfills many purposes. It can serve as a core for experimental laboratories and an outpost for managing scientific observations and services from space. In can assist commercial enterprises, be a construction base for assembling very large orbital structures needed for information and communications systems, and for collecting solar energy for use in space, or at least experimentally, for use on Earth.

A program of space leadership would deliver economic and inspirational benefits for the United States, and the world.

George M. Low

Taken from remarks made at a session of AIAA's February Annual Meeting.

SOONER OR LATER

Only an extremely brave—or equally foolish—man would attempt to dogmatise on the space achievements of the next decade. The past two decades have seen the transformation of writers' dreams into reality, and there is no reason to doubt that either man's imagination or his technical prowess has diminished. On the contrary, as Salkeld shows in his article, the ideas keep bubbling up, and the technological achievements are still managing to keep pace. The limiting factor during the next decade is likely to be the growing insistence of governments to invest money in space programs only in relation to their foreseeable utility. This trend will certainly continue throughout the coming decade and a reversion to the large prestige projects of the recent past is unlikely. Thus, space managers must try to invest available funds in such a way as to respect the wishes of their masters and at the same time make some modest progress toward the programs which sooner or later must come: large constructions and habitation in space.

I, too, am hopeful that this next great step forward will encourage international cooperation, but this will not come of its own accord. It will require constant vigilance and tolerance, but the opportunity is too precious to miss. **Roy Gibson**

FRESH VIEW FOR PRC

Since the first successful launchings, people have not only made artificial Earth satellites to be beneficial to mankind—for instance, they have not only developed communication, navigation, Earth-resource and meteorology satellites, but also created a lot of new scientific research fields which have become new subjects, such as space astronomy, space geology, and space chemistry—as a result of the development of space technology. Also mankind has made some valuable achievements in near-Earth, Sun-Earth, and outer-planet explorations. The development of space science and technology clearly has broad prospects.

I cannot comment in any official way on the plausibility of Robert Salkeld's article on living in space, but I enjoyed reading it and have not previously seen such detailed conceptions for Earth-orbital research habitats. **Chen Jie**

Vol. 29, No. 1, January-February 1978.
pp. 2-20 with permission of the copyright
holder.

FAR FROM being isolated in space, Earth is a spaceship with external supplies. The most fundamental commodity, energy, comes from an external source. Terrestrial environment and the biosphere run on the 1.5 billion billion kilowatt-hours of solar energy intercepted annually.

Earth and space are indivisible. Only a few centuries ago did man begin to understand this indivisibility in terms of natural laws. Now we experience it by going into space and returning at will and by conversing with our automated scouts all over the solar system. In a few years this indivisibility will express itself in the productive industrial use of extraterrestrial environments.

38-036 O - 84 - 60

There was a time when man was slow to accept the mounting evidence that Earth is not flat. Today it is necessary to understand that we do not live in a limited, isolated, closed world. Our world is open to the cosmos and contains all the future and growth potential the human mind can envision. But ours is not, and probably never will be, a problem-free world.

Humanity faces the most complex task of its history so far. Stated in a solution-oriented way, it is necessary gradually to reorganize this planet at two levels. One must deal with the competing necessities of biosphere and mankind with all their environmental and climatic consequences. On the other level, it is necessary to resolve the demands of competing nations and worlds within mankind's hierarchy of socioeconomic developmental levels and the "Christmas tree" of sociopolitical, ideological, and military consequences.

The way to solve a problem is to forge concepts that permit one to look beyond the problem. Even today's conflicts between humankind and the environment, so seemingly insolvable to catastrophists and antitechnologists, can be turned from conflict to juxtaposition of interests in the crucible of higher concepts. Such a concept is the realization that we can enhance the "supplies" to spaceship Earth, beyond energy, to include materials and information acquisition/transfer for the mainstream of human civilization.

We have not yet exhausted outright any needed resource. There are vast land areas, such as the Sudan and others, that could feed all mankind once developed. Minerals and energy abound on Earth and beyond if we have the resolve to develop them rather than retreat into stagnating stupor that would hurt our environment more than the advance of a benign industrial revolution taking into account terrestrial and extraterrestrial environments. Technology will not be the cause of our demise, but lack of willingness to advance it beyond the early, transitional state may be. Technology is the source of our options.Options are the basis of a future that keeps us above the level of pawns. Those who condemn technology, properly applied, eliminate our options. They commit the worst of all pollutions—the pollution of our future.

To find the approaches to solutions that can properly safeguard the future of our civilization with its unparalleled contributions to the human factor of life, we need a better understanding of what we face. We need insight into the long past that shaped us and set our course—back to life's silent and successful struggle for survival and growth on a primordial planet.

The Extraterrestrial Imperative is a manifestation of larger evolutionary cycles—an integral part of life's commitment to expansion and growth. The reality of the biosphere testifies to this fact. This splendid system assures our planet's unique position as a colony of life for the duration of our star, unless the climatic or genetic foundations are destroyed. When the planet's accessible (organic but abiotic) energy sources became exhausted some three billion years ago, life's response was a vigorous struggle for survival through growth. Certain organisms developed the enzymes needed to utilize solar energy. This shift to an extraterrestrial source was the first great industrial revolution on our planet. Driven by solar energy, the evolving chlorophyll molecule became the technical instrument by which to turn primordial energy and matter into chemical energy in biotic organic compounds. Mass production of the basic staples of life was initiated. The by-product, free oxygen, began to pollute the chemically nonaggressive environment of Earth and became a self-induced growth driver by which life stimulated itself into a giant evolutionary advance—a global biosphere—catapulting intelligent life into existence.

The point is that technology is as old as life. Technological advances and enlargement of the resource base beyond the limits of this planet became the bridge for survival and

growth. A system evolved, so stable that it could tolerate the ascent of a new, intelligent life form able, in turn, to interact with primordial matter through its own technology. This is the basis for the new thrust of the Extraterrestrial Imperative. For small planets, such as Earth, the extraplanetary imperative is a necessity to ensure long-term survival. In return, this imperative offers a higher, virtually unlimited, evolutionary ceiling than appears available to much larger, exclusively planetogenic bioworlds as might have arisen on Jupiter.

The fact that neither technology nor reaching beyond Earth is exactly new, but natural growth options exercised before, puts the human reality of our time into perspective. The reality has two anchor points: (1) That the chlorophyll molecule and the human brain are the only true superpowers on this planet. They must find a way to coexist, and, not being intrinsically incompatible, they can. (2) That humanity does not live as a mankind but is "organized" as an aggregate of some 140 nations. Most of these nations strive to improve their standard of life or safeguard social standards achieved and extend them to the less advantaged. Without the means to grow—and, like it or not, these means include material resources and the ability to process them—general stagnation will create a shrinking-water-droplet world in which competition for growth turns into a grim struggle for survival.

In an industrial civilization, all nations tend to profit from technoscientific advances made by some. In a shrinking-water-droplet world, this humane symbiosis cannot last. When it breaks down, it will pull all into a maelstrom of regression, burdening both the biosphere and the hard-won standards of our civilization—possibly to the breaking point.

Space industrialization as a phenomenon of human development presents the systematic breakthrough into a new Open World at a time when many formerly open world characteristics on Earth (resource abundance, waste sink capacity) fade, and the terrestrial environment begins to assume the appearance of a closed world in relation to human activities. This has two important consequences: To man, the cause of the devolves the burden of preserving the terrestrial environment. Without projecting his productive capabilities beyond the terrestrial environment, man will not be able to carry the burden in the long run without severely stunting the human growth potential.

We cross into the new Open World through a multitude of environmental frontiers—subatomic, atomic, molecular, the cosmos of the human mind, and the cosmos of the universe. In pragmatic terms, in the Open World new environments are what it is all about; they are the source of all national wealth, the basis for all new options. Through their exploration and productive use (industrialization) both the spiritual and the material causes of mankind are advanced.

This concept permits us to see beyond what seems to be an irreconcilable confrontation of man and environment, unless humankind backs down into a no-growth mode. Our technology supports both of our main strategic options—a benign industrial revolution on Earth and an extension of our industrial capabilities beyond Earth. We can see more clearly that we are not stonewalled; we have choices. Therewith the buck stops again right here, with us. It leaves us a choice between two ways of life of either organizing scarcity or creating wealth.

Organizing scarcity reveals the resolve of a viable society to meet and overcome a state of need. The emphasis is on overcoming, because a healthy society will reject the notion of managing scarcity (not to be confused with prudence) as a way of life. Creating wealth is the natural state of life, and mature men and women understand that this is not synonymous with ever increasing consumptive affluence but is equally the basis

for safeguarding and developing human values. Current criticisms of industrial lifestyles, which in fashionable zeal tend to exceed the bounds of justifiable cause, should not blind us to the fact that success in creating wealth underwrites a degree of human freedom and a level of social services unmatched by any other lifestyle or civilization, past or present. The quality of these industrial lifestyles sparks the incentives and sets the goals in many developing societies equally determined to set their own shade of life within industrialization. Greater productivity leaves more time to services and human development. Industrial progress without increased burden on the human environment prevents increases in productivity from becoming self-defeating.

The three initial space industrial product areas are information, materials, and energy. Once set up properly, space industrial systems in each of these areas are exceedingly productive. This has clearly been demonstrated by satellites for information transmission and sensory information acquisition. It is equally true for the energy and the material processing sectors. Through the development of space-related industries in the sectors of electronic (information-related) services, products, and energy, new jobs are created. The industrial resource base is broadened. The economies of industrialized and industrializing countries are strengthened. Public health and social services will benefit. The industrial use of space in the information services sector is already a reality, although the potential is far from exhausted. Beyond 1980 the Space Shuttle-based Space Transportation System (STS) will form the economic basis for broadening the commercial applications in the information sector as well as for developing the energy and product sectors.

Information transmission satellites have made great progress in the past decade in global communications, from Intelsat I (1965), with a capacity for 240 telephone circuits, a design lifetime of 1.5 years, and an investment cost $32,500 per circuit-year, to Intelsat IV-A (1975), with 6000 circuits, a lifetime of 7 years, and $1100 per circuit-year. Between 1965 and 1972, the typical Intelsat user fee per circuit-year had dropped from $32,000 to $9375. In 1979, Intelsat V (with ten years lifetime) will come on line, doubling the number of circuits at a possible cost reduction to $500 per circuit-year. Of growing importance is the field of domestic communications satellites, using channels leased from Intelsat spacecraft (as have Algeria and Norway) or dedicated satellites (U.S., Canada, Indonesia). Data exchange satellites, designed for the transfer of wideband, high-rate data blocks rather than voice or TV circuits, are under development for the business market in the U. S. and Japan. These will be the first to use rooftop terminals.

The increase in satellite antenna size, channel numbers, and radiated power, made possible by the STS, will accelerate the trend

toward increasingly smaller Earth terminals. Direct-broadcast satellite systems and communication satellites to mobile terminals down to personal communication via handheld or wristwatch tranceivers will then become realities in the 1980–90 decade. The latter group, in particular, has no competition from hardware links on Earth and only marginal competition from high-frequency radio. A first step in this field has already been taken. Marisat, stationed over the Pacific, Indian, and Atlantic Oceans, provides shipboard and mobile offshore telephone circuits.

Behind these technological advances lies a momentous contribution to modern society. In the nineteenth century, economic growth rested on mass transfer, the transfer of goods from one location to another. In the first half of the twentieth century, the economic foundations shifted to the transfer of energy. Now, as society is based increasingly on services, information transfer will continue to rise in importance well into the twenty-first century. Beginning in the 1980s, growing numbers of people will telecommute rather than commute to work. If, by 2000, the expected mileage traveled in this country is reduced by 18 percent, the annual fuel savings correspond to some 700 million barrels of oil (at an average of 27 mi/gal) and at least $28 billion (at 60¢/gal and 5¢/mi).

There are more than 200,000 doctors' offices in this country today (general practitioners, specialists, and federal offices). Interconnection by office-to-office communication links permits such advances as ready consultation with specialists anywhere, instant updating on diseases, treatments, and medications, and expanded use of paramedics in mobile units. Eventually a global medisat system will make "home type" medical services available in the remotest areas, based on signals or even pictures defining the patient's state to supervising doctors. In developing countries, public health services can be improved much faster and at a far lower investment than could be hoped for without satellites.

Similarly expanded opportunities are provided in education, including special services to the handicapped and televised instructional courses for general education. To increase adult living competence is a much-needed service in our fast-changing time. Televised instructional courses with massive "enrollments" of tens to hundreds of thousands would reduce cost from hundreds to a few dollars per participant. Public order and safety, electronic mail directly to our homes, teletraveling, teleshopping, new ways of contacts between peoples all over the world, the expanded opportunities to tune into major scientific and cultural events anywhere in the world—including, eventually, activities in orbit, on the Moon and beyond—are other promises of the emerging era of space-based information transmission.

But the explosive growth in the capacity to transmit information also means an equal growth in the capacity to transmit misinformation. The potential for manipulating people's minds will increase accordingly. Again, the buck stops on the human desk, since technology itself is neutral. However, these dangers are a blessing in disguise. How else can we improve unless we face the dangers we pose to ourselves? It is the way of nature to immunize through infection, not to protect by creating a sterile environment.

The other branch of information services, namely, sensory information acquisition, is rapidly becoming integrated into the mainstream of economic and environmental activities worldwide. The well-known services from weather forecasting to crop measurement already are worth billions of dollars in agriculture and forestry, pollution control and public health, tourism and leisure time industries. As population, industrialization, and urbanization increase, reliance on

information acquisition from space for the management of food, water, and land and ocean resources will become indispensable. Our sensitivity to climatic variations will grow. Therefore, beyond weather forecasting lies the challenge of understanding the mechanisms and dynamics of regional and global climatic variations. NASA's plans for a large, eventually manned, Solar-Terrestrial Observatory in the late 1980s are of crucial importance. Certainly, by the turn of the millenium, the ability to assess man's impact on climatic changes and the ability to forecast regional or global climatic variations will have become critical to the survival of civilization.

To educate without offering prospects for utilizing the improved human resources through meaningful employment can have destabilizing social effects. In industrialized countries, and even more so in developing countries, education must go hand in hand with economic growth to ensure adequate job markets in the production and services sectors. Here the key is energy.

Our present energy world is shrinking rapidly as continued global industrialization demands its expansion. To reverse this process, the development of coal, fission, solar, and fusion sources must be pursued. The age of cheap, abundant energy need not be over; but it is not only vital to our time, it is the most important heritage we can bestow on succeeding generations to ensure their quality of life on a planet from which we skimmed the richest and most readily accessible resources. In the energy sector, more than in any other, the future depends on *our* problem-solving capacity, for, as our bodies cannot exist long without breathing, our industrial civilization cannot last through a prolonged period of lack of available energy. Therefore, we cannot leave this problem to posterity. Our problem-solving capacity, in turn, is enhanced by adding a new industrial option bank in space.

In the space energy sector, one must distinguish between using energy in space for material processing and production, in order to reduce energy consumption within the biosphere, and utilizing space as a source of energy for use on Earth.

Photovoltaic systems are a natural for supplying energy to orbiting information and manufacturing systems. Here, NASA-planned power units from 50 to perhaps 1000 kwe size will be adequate, at least for the 1980s. For example, a very advanced person-to-person comsat with 1.2 million channels requires about 600 kwe.

Most anticipated space manufacturing processes indicate power requirements within 500 kwe. Due to the strength of the gravitational pull of Earth and the associated transportation costs, only items of relatively low mass but high quality and product value are economically competitive. In the lunar-industrial product sector, on the other hand, larger masses and cost-effective extraction of desired elements from lunar minerals and oxides are the key to economic viability. Here much higher power levels are involved. Unavailability of solar energy during lunar night and the desirability of underground extraction render fusion power particularly attractive.

Controlled fusion power is the key to the ultimate economy and versatility of space industrial productivity. Consequently, plasma research and experiments toward fusion reactors should be given high priority early in space industrial research and development planning. Fusion reactors are complex, with complex auxiliary systems for plasma heating and fueling, complicated blanket and shield structures, energy storage and tritium recovery, and handling. Nevertheless, it appears that operation in space can reduce many of the most difficult engineering problems. A magnetically confined fusion plasma requires a surrounding vacuum of 10^{-6} torr (1.3 billionth of an atmosphere). At lesser vacuum, the plasma pressure becomes impractically high. Space offers a vacuum of 10^{-9} torr or less, greatly

reducing plasma and required pressures.

Terrestrial vacuum chambers are relatively small because of the difficulties and cost of maintaining such high vacuum on the ground. Since 80 percent of the energy released by a deuterium-tritium reaction resides in neutrons that cannot be confined magnetically, the inner chamber walls are exposed to savage neutron flux densities, creating an environment that is comparable only to that close to a detonating hydrogen bomb. The resulting material problems are correspondingly severe. Moreover, wall particles are released as impurities into the vacuum. When these impurities get into the plasma, their presence raises the energy transfer by radiation out of the reaction zone, cooling the plasma, causing plasma instabilities, and possibly killing the reaction.

In large vacuum chambers, whose construction poses no basic problems in space, the neutron flux density to the wall is reduced, among other advantages. Thermal stresses, blistering, embrittlement, and other damage are reduced. Maintenance problems are facilitated, and the useful life of the material structure is prolonged. With more internal volume available and with the high external vacuum, conditions are greatly improved for overcoming the impurity problem. Additional advantages (also for terrestrial fusion plants) may be derived from space-manufactured stronger (more homogeneous) refractory metals or other alloys suitable as inner wall material.

For use on Earth, a transmission system must be added to the energy unit. Through space, energy can be transmitted at any wavelength of the electromagnetic spectrum. But for transmission through the atmosphere, only selected wavelength regimes are suitable—primarily in the visible and the 10 to 15 cm wavelength microwave region. Transmission in the visible requires the redirection of sunlight by reflectors (space light). Microwave transmission must use large antenna arrays generating a coherent (i.e., laserlike, nonspreading) beam. Much smaller antennas are required if laser frequencies are used (for example, CO_2 laser light in the infrared). But they appear practical only for energy transmission into the upper atmosphere (e.g., to power aircraft at high-altitude level flight) but not to ground stations.

For Earth, the solar option is particularly enhanced by space light beaming to Earth the most versatile and ecologically best integrated energy source. The reflector size and number are tailored to their functional requirements—night illumination (Lunetta), power generation (Powersoletta), and photosynthetic food production enhancement (Biosoletta). Typically, Lunetta and Powersoletta circle Earth at 4200 km once every three hours, continuously in sunshine (sun-synchronous orbit). The large Biosoletta system preferably orbits in a slightly elliptic, 24-hour orbit, highly inclined to cause minimum, if any, interference with communication satellites in equatorial geostationary orbit.

Lunettas can serve urban areas, remote industrial activities, rural areas in developing countries to facilitate night work where needed, and disaster areas. Controlled light is provided to specific targets for specified periods without cables and fuel consumption. It can be delivered quickly, removed without a trace, or furnish reliable, high-quality urban lighting even at cloudly skies or in fog, without danger of blackout.

Present city lighting, averaged over the urban area, equals about that provided by two full moons high in a clear sky. Most outdoor lighting requirements correspond to an illumination equivalent to between 100 and 1000 moons, in farm areas 50 to 300 moons. A Lunetta system with clear-sky illuminance of 700 moons (over 100 moons even at strong overcast) needs some 3.6 sq km of reflecting area, divided into 15 to 20 reflectors. Since they move across the sky, additional reflectors must be installed, raising the total to 27 sq km, but

more than one city may be served. Individual reflectors appear as stars some 1500 times as bright as Venus—a beautiful sight, illuminating the city gently but distinctly from several directions.

Powersoletta enhances solar energy supplies to earthbound solar-electric central power stations. Reflectors (10 to 50 sq km) with a cumulative area of 1530 sq km beam one solar constant to a 1200 sq km ground area. Because of their motion, 11,500 sq km reflecting area must be installed. But at least three ground stations can be served in a latitude belt between 30 and 50 degrees. Powersoletta removes geographic constraints on solar central power siting. Latitude becomes comparatively less important than low-average overcast.

A ground station, at 1000 sq km of solar cell banks and 15 percent conversion efficiency, operates around the clock, yielding a net annual output of 45 to 65 million kilowatt-years, depending on local atmospheric conditions. Energy storage for baseload power is minimized. The output is of great economic and environmental significance. Over a three-year period, a 55-million kw-year annual output consumes 339 or 552 million tons of oil or coal, respectively; or requires a loading of 1807 metric tons of uranium in light water reactors, generating 63.2 tons of assorted fission products, 16.1 tons of plutonium isotopes, and 9.5 tons of long-lived waste.

People living within at least 50 km of the power station will experience night light intensity between midnight sun and bright aurora, due to light spillover. This could be avoided by operating Powersoletta at daytime. Certain reflectors are turned around to the Sun, beaming at those reflectors best positioned at the time to service the power station. The retroreflection technique may cut the reflecting area by some 30 percent. This technique requires extensive energy storage but no enlargement of the receiver area (the most expensive addition) because of double irradiation.

For the night Powersoletta, a cost at the bus bar of electricity (in 1977 dollars) of about 50 mils/kwhe is indicated during a 30-year amortization period, about 20 mils/kwhe thereafter. For the daylight system, 35 to 40 mils/kwhe and 15 mils/kwhe, respectively, are indicated. These numbers include a ground station cost of over $1000/kwe, twice the Energy Research and Development Administration (now Department of Energy) 1985 goal of $500/kwe.

The reflectors with adjustable facets use structures of carbon epoxy and fibers and membranes of kapton. All parts are coated in space with the optically best material, sodium. Recoated and serviced at about ten-year intervals, the reflectors should last 60 to 100 years. At a resulting sodium consumption of 1500 tons annually, a service station may be established at libration point L-4 or L-5 in lunar orbit, supplied with sodium mined on

the Moon (measured abundance in lunar samples 0.2 to 0.5 percent). The reflectors can commute to lunar orbit by a combination of solar pressure and electric thrust—in 300 days or less transfer time at a reflector weight of 75 tons/sq km.

To prevent night frost damage, Powersoletta excess reflectors can beam temporarily at the cold area to raise local temperatures and thereafter be reoriented to the power stations.

Biosoletta is applied most effectively to fertile ocean regions lacking sunlight for achieving full productive potential; that is, to circumpolar upwell areas. At some 100,000 sq km, the irradiated area should be ecologically self-contained. Seafood is a vital protein supplement. Based on Antarctic production figures and a 40 percent utilization factor of seafood produced, a Biosoletta alternating in 12-hour intervals between a 100,000 sq km "macropond" each in Arctic and Antarctic waters (50 to 70 degrees latitude) could generate an annual Antarctic yield alone of the daily protein supply (36 grams in about 220 grams of seafood) for 180 million people. Again, the Biosoletta reflectors can be serviced at a libration point to which they solar-sail in ten days to three weeks.

Even Biosoletta's energy influx constitutes barely 0.08 percent of the Sun's energy influx and, therefore, cannot affect the global climate. Locally, cold winds and strong currents dissipate the thermal energy rapidly. Biosoletta furnishes make-up radiation energy to power carbon assimilation. Solar radiation in polar regions delivers 0.7 trillion kilocalories per sq km per year, compared to between 1.2 and 1.6 trillion kg-cal/sq km year in tropical waters. Biosoletta "photon-fertilizes" two tiny but bioproduction-intensive "macroponds" (each about 1 percent of a 5-degree belt at 60 percent latitude) to approach the solar level at low latitudes.

Compared to Powersoletta, the microwave-type Space Power Satellite (SPS) alternative has a number of advantages and disadvantages. The advantages are reduced atmospheric losses, especially due to overcast, and the ability to shape the beam, thereby being able to irradiate relatively small areas from geostationary orbit; whereas a reflector's focal area increases with distance (barring costly special arrangements) and is about 100,000 km² from geostationary orbit. For this, however, SPS pays with greater complexity of its space component. The system must accept the primary energy, convert it to electricity, convert the electricity to microwave energy, and shape the microwave energy into a beam of required specifications. If the primary energy

is solar, the low-radiation density determines the system's size (80–120 km² for delivery of 10 million kilowatt at ground outlet) and its weight (50,000 to 75,000 tons for 10 million kilowatt), independent of the conversion system (photovoltaic or solar-thermal). For fusion as primary power, the waste heat radiator becomes the primary driver of system size and structural mass, depending on the conversion system. Generally, smaller sizes and weights are indicated. Powersoletta's thermal input, while far from critical, is higher, but a large number of microwave beams, each carrying millions of kilowatt power, may not be the publicly preferred option.

The disadvantages of the SPS are rooted primarily in the fact that microwave radiation at significant power densities is not part of the solar radiation input into the terrestrial environment. One consequence of this concerns ionospheric radio frequency interference, which causes power loss and can cause ionospheric heating. Through the limitation of maximum power intensity in the beam to about 17 percent of the Sun's radiation energy flux in the ionosphere (1.35 kw/sq m), this effect can be kept within acceptable limits. However, safety limits force the density at the beam's periphery to much lower values so that, including a safety zone around the receiver system, the required land area corresponds to an energy influx of about 2.5 percent of a solar constant on the ground (1 kw/sq m). For Powersoletta, the output per unit land area is about twice as large. Thus, SPS requires much more receiver land area than Powersoletta, even though the microwave beam can be shaped.

Space manufacturing looks commercially promising for a wide range of products. These lie primarily, but not exclusively, in the pharmaceutical, electronic, and optical sectors. In the pharmaceutical sector, it becomes increasingly desirable to separate and concentrate living cells capable of producing medically important substances. Under zero-gravity conditions in space, living cells, whose mass/charge ratios differ, can be separated efficiently and accurately by applying weak electric fields (electrophoresis). The effectiveness of this method is strongly impeded in the presence of a sizable gravitational force.

Electrophoresis has a wide range of medical and biological applications. An early promising use is the isolation of human kidney cells that produce the enzyme urokinase, a substance with the potential of effectively preventing and dissolving blood clots. Even at a present cost of $1200 per dose, the 500,000 doses currently needed annually in the U.S. alone cannot be produced by the present method that extracts one dose of urokinase from more than one ton of urine. The electrophoretic method can also be applied to separate other kidney cells that produce erythropoietin (an antianemia hormone stimulating the production of red blood cells in bone marrow); to a host of enzymes (blood proteins) controlling a wide variety of metabolic functions (and malfunctions); to white blood cells and antibodies (affecting tumor growth, transplant rejections, etc.); to chromosomes (X-, Y-types, affecting composition of cattle population through artificial insemination); and, possibly, to nerve cells (neurology). Even this list is not exhaustive. The consequences to medical and biological science and practice—from preventive, even predictive, medicine to agriculture—cannot even be estimated today.

In the electric/electronic product, value lies in the growth of mono-crystalline semiconductors of highest perfection and purity for a wide variety of applications. The same space features of null-gravity (eliminating convection currents in melts) and

ease of levitation melting (no contamination through wall contacts) also permit the production of glasses of very high purity and optical quality as needed for high-power laser systems, fiber-optic transmission lines, and high-resolution optics.

The list of already recognized potential products is much longer. All meet requirements of high value and low mass that give them commercial viability and could favorably affect the balance of payments of the United States and other industrialized nations vis-à-vis the rising costs of raw materials from developing countries. From there, other product lines lead to larger mass items and special products for larger space systems. In the larger mass items category, for example, is the production of new metal alloys and near-perfect, friction-free bearings and pistons by alloying metals of widely differing specific gravity (which causes them to separate at surface gravity), such as aluminum and lead alloys for bearings and pistons. Automobile manufacturers have long attempted at great expenditure to create such alloys that could give many automotive parts a capability of at least 500,000 miles. Two items exemplify the products-for-large-space-systems category: the aforementioned use of sodium for coating space reflectors and the production of ultra-light (for operation in a low-g environment) high-quality solar cells.

Lunar material contains industrially valuable materials. The world reserves of some of these appear limited at present. But several factors militate against major imports to Earth of zinc, copper, nickel, manganese, or titanium from the Moon (or from translunar sources, such as asteroids). In some cases, technological advancements will lead to the commercial exploitation of progressively poorer grades, thereby enlarging terrestrial land reserves currently not counted. Large mineral deposits become accessible on the ocean floor. Recycling and substitutions offer additional options for stretching terrestrial metal supplies. Job considerations in the primary (extractive) and secondary (refinement to semifinished products) metal industries are an additional factor since it takes a long time to phase out such industries, especially in developing countries, prior to relying on large-scale extraterrestrial imports. This leaves as a comparatively closer prospect the advantages of the lunar environment (vacuum, low-g conditions at the surface, zero-g in an orbiting lunar factory) for generating superior products of comparatively high market value but larger masses than those that are most suitable for Earth-orbiting factories. Access to low-gravity supplies can also be important for large space constructions as are typically involved in the energy sector. For these, however, the most attractive construction materials (graphite composites, graphite fibers, epoxies, poly-imides) are not available on the Moon. Therefore, the opportunities of taking advantage of lunar gravity to obtain construction materials for large space systems appear limited.

However, associated with the large masses of these systems are significant transportation requirements from Earth. If oxygen-hydrogen orbital transfer vehicles (OTVs) are used to lift these masses from near-Earth orbit (NEO) to outer, especially geosynchronous orbits (GSO), then, for each 100,000 metric tons of construction material delivered to GSO, the launch system must deliver also about 290,000 tons of oxygen to NEO for the OTV (plus 60,000 tons of hydrogen). For each ton of payload delivered to NEO, an advanced launch vehicle burns 11 to 15 tons of propellant in the atmosphere, releasing 8 to 11 tons of water vapor and 37,000 to 47,000 thermal kilowatt-hours. Whether the oxygen must be supplied from Earth, therefore, makes a difference of some 3.7 million tons of propellant burned in the atmosphere per 100,000 tons of cargo to GSO.

Lunar oxygen, therefore, can be an attractive substitute, especially since it ranks second in abundance behind silicon, and it can be

extracted in large quantities by means of fusion power and requires no further processing. Of course, the need for oxygen can be eliminated by employing electric or advanced nuclear propulsion. But each of these alternatives has its own set of disadvantages and problems that keep the use of lunar oxygen a competitive option, especially since a lunar oxygen industry opens up a lunar industrial capability whose implications are not restricted to transportation. Another potentially attractive early option is a lunar service industry with selective resource utilization, taking advantage of low gravity availability as well as vacuum conditions on the surface. A case in point is the libration-point service station for Soletta reflectors with sodium and other selective resources supplied from the Moon.

Thus, the industrialization of space offers a new dimension of technology and productivity with a vast scope of opportunities in terms of electronic services, solar energy for Earth for illumination, electric power and food production enhancement, space factories, space fusion, and lunar industrial potentials. However, a great deal of hard-nosed research and development and of pragmatic, balanced in-depth assessment is necessary of the many opportunities as they come up. There will be disappointments as well as pleasant surprises.

More profound and inspiring than the technology, however, are human and socioeconomic implications. Understood in the perspective of the Extraterrestrial Imperative, space industrialization is the crucible in which the seemingly irreconcilable problems that cause such profound pessimism in the outlook of many can be resolved. Earth and space become one through the intelligence and the creativity of man.

IN conclusion, let us take a brief look beyond. In the perspective of the evolutionary thrust of the Open World of Earth-space, exoindustrial productivity may be regarded as the first phase of extraterrestrialization, that is, the process of living in more than one world. The industrial facilities of this phase are Earth-related, directly or indirectly, as they should be. The people who make up the industrial teams in orbit or on the Moon are and remain terrestrials.

The people on Earth benefit from space industries. They are not asked to foot the bill for huge autarkical, colony-type factories housing thousands who, in turn, deprive terrestrials of even larger numbers of jobs.

The economic function of space industrialization is to generate jobs on Earth, not in space. Its most important international function is to assist in reducing the gap in the economic development of our global "North" and "South," *not* by lowering the standards of the North but by raising those of the South. This implies continued global industrialization. But as the world keeps industrializing, global competition for our country will increase and continue to erode the job base. Thus, for domestic as well as international reasons we need to open up a new industrial territory and make it work for people right here on Earth.

As the space industrial capability level and the skill of productive space utilization advance, the number of people living in space for a major fraction of their life span will grow. These people will develop new preferences as to g-levels and lifestyles no longer necessarily related to terrestrial physical or social conditions. They will "urbanize" their new worlds. Space stations and lunar abodes will become their primary home—Earth a place to visit or perhaps just to "experience" holographically, in the comfort of their gravity environment. The more antiseptic surroundings in space settlements could reduce resistance to diseases of those who live in them from birth. They may find the hygiene

of Earth just as hazardous as we would find the hygiene of medieval cities or ancient Rome. Still, some space-born offspring may migrate back. Those who stay will continue to diverge sociopsychologically from the ways of terrestrial mankind, as Americans have diverged from their ancestral countries. They will become the new *Homo Extraterrestris* who no longer needs Earth, hence does not wish to simulate its environment slavishly.

Their readiness to achieve sociopolitical and resource independence will grow with the psychology of their extraterrestrial motivations and their technological ability to create new worlds in their totality. This will lead to Androcell, not a colony of Earth, but a *sovereign, mobile neocosm*. Androcell is the new beginning, while back on Earth open-world conditions move toward a demographic and industrial equilibrium.

The Androcell phase is likely to follow the intermediate phase, exourbanization. Oversimplifying somewhat, one may say that exoindustrialization puts the machines and productive techniques into space; exourbanization introduces the human and biological elements; and extraterrestrialization integrates the two components into complete neocosms.

Each of the three evolutionary phases is justifiable by clearly identifiable prime objectives as well as by their impact in changing the consequence world. Each phase contributes to the capability *and* motivation to progress to the subsequent phase. In the third phase, we leave the harbor and emerge into the open sea of space, psychologically and socially speaking. Human history henceforth will pulse through many world-arteries that lose themselves beyond the horizons of our present perception in the trackless infinity of space and time.

The civilization of the Androcell is truly three-dimensional, not only because the design of Androcell utilizes purposefully all gravity levels between axis and periphery of the rotating systems; but, more important, because living awareness between worlds, and between surfaces and Androcells, plays itself out in three-dimensional space. Through exoindustrialization (production facilities), exourbanization (Astropolis, Selenopolis) and neocosms (Androcells), the human life form may be regarded as returning to the three-dimensional origin of all terrestrial life. The two-dimensional existence of Earth's land surface becomes an evolutionary benchmark wedge between the three-dimensionality of the finite oceanic womb from which life rose to the brightness of consciousness and the infinite cosmic womb in which it can rise to a level beyond our understanding.

How a small group of adventurous women, and a million-dollar toilet, helped NASA take one giant step for womankind

BY BARBARA ROWES

HOUSEWIVES IN SPACE

PAINTING BY RALLE

Two and a half years before John Young and Robert Crippen first fastened their seat belts aboard the space shuttle *Columbia*, NASA slipped this ad into the classified pages of the San Francisco *Chronicle*.

TEST PARTICIPANTS SPACE TRAVEL PROJECT We need female paid volunteers ages 45-55 to take part in an experiment related to space travel. Nonsmokers preferred. Must be able to adjust to horizontal semiconfinement of 24-hour day.

It wasn't until the following afternoon, in an upper-middle-class section of Oakland, that a gray-haired housewife got word of what would be, for her, a fateful mission. Around 14:00 hours she happened to turn on her kitchen radio. "Whenever I season a chicken," the energetic, fifty-four-year-old Lynn Luthi says, "I get my inspiration from country and Western." Shortly afterwards station KNEW broadcast the ad as a public-service announcement. "The instant I heard the word *NASA*," she recalls, "it was the beginning of an immediate love affair."

With one hand on the chicken, she dialed NASA. Busy signal. She was undaunted. "I made up my mind to get in there if I had to sit by the phone for the next twenty-four hours." Two days later she was still getting a busy signal. "Even while doing my shopping, I was trying to call NASA, direct from the supermarket," she recalls with a smile.

For the first time ever NASA was actually recruiting women for a historic Earth-bound, exploratory mission at its Ames Research Center in Mountain View, California. The women weren't female astronauts or military personnel, but average women — housewives, teachers, corporate administrators, journalists, secretaries, nurses, and doctors. And they have paved the way for female astronauts who will shuttle into space in the near future and for women of all ages to fly aboard the space shuttle as passengers in the distant future.

These women, chosen from hundreds of candidates, are the unknown heroines of the Space Age. They all took part in a NASA study officially known as Shuttle Re-entry Acceleration

Tolerance in Male and Female Subjects Before and After Bedrest, but unofficially and affectionately dubbed Housewives in Space. As a result of the extraordinary stamina and spirit that they demonstrated, they proved conclusively that women, as well as men, have the "right stuff"—not only to survive but to thrive in space. They also added volumes of data to the skimpy body of research NASA had on women's adaptability to space travel.

Before April of 1977, when the first crew of women were unpacking their suitcases for their stay at the Ames medical facility, NASA had not investigated the physiological responses of women to space travel. In the weeks that followed they went through the same battery of tests given to a select group of men, tests designed to see how well they would withstand the crushing g-force of takeoff and reentry from space, the debilitating effects of weightlessness, and the challenge of performing coolly and efficiently in a state of total physical exhaustion.

The Ames medical study represents a major breakthrough in space development for the American woman. NASA has done hundreds of medical studies over the past few decades, but as late as 1972—years after the first Mercury mission—only one of these involved women, and that included a lone female subject.

It wasn't that women had been passively sitting back, contentedly Earth-bound, while men rocketed off into space. In 1962, three years after the Russians revealed they had already been training a female cosmonaut, a House of Representatives subcommittee held a little-noted hearing on sex discrimination and astronaut selection. On July 17, thirty-one-year-old pilot Jerri Cobb testified that NASA had tested 25 female pilots and had found 13—including herself—qualified to become astronauts. Cobb went on to excel at all the other qualifying tests, but she ultimately was caught in a military catch-22: NASA required that each potential astronaut be a test pilot, and female jet pilots were rare.

So for the next ten years Cape Canaveral, where astronauts roar beyond the *terra firma* of sex discrimination, was virtually a man's world. Although women played supporting roles as nurses, scientists, and engineers, they were always left waiting by the launchpad at liftoff. Their situation finally began to improve in 1972 when the government approved the budget for *Columbia*. By then it was taken for granted that at least one woman would be strapped into a shuttle seat sometime in the future.

Why were women, deemed fit for passage on the shuttle, but not in a rocket? "A lot of reasons were tossed around," says David Winter, formerly the director of life sciences for NASA, "but the main one was that until the shuttle came along, there was no way to manage women's waste. If you can't handle a basic physiological need like that, you can't go anywhere." And so on board the shuttle is the last piece of technology needed to liberate space: a $3 million, unisexual, zero-g toilet that accommodates the male and female anatomy. Equipped with handholds, footrests, and a seat belt, it uses a suction fan to simulate the gravity that makes toilets on Earth work so well.

Shortly thereafter Dr. Winter and his farseeing associate, Dr. Harold Sandler, chief of the Ames Biomedical Research Division, recruited 12 Air Force nurses, between the ages of twenty-three and thirty-four, as volunteers for the first study of female fitness for space travel. Although the experiment was limited, the results indicated that neither body chemistry nor anatomy interfered with a woman's capability to withstand the stresses of weightlessness. Encouraged by these findings, the NASA experts spent three years meticulously planning a more detailed medical study designed to see whether women were the equal of men in adapting to the stresses of travel to and from space.

NASA has done hundreds of medical studies over the past few decades, but as late as 1972 only one of these involved women, and that had a lone female subject.

This new study, unlike all the others, was to be co-ed. Winter and Sandler planned to spend five years putting three different age groups—each consisting half of men and half of women—through exhaustive tests on a rotating basis. In 1976 they began with the first group, thirty-five- to forty-five-year-old men, followed by a group of women in the same age spread. The project moved through the forty-five to fifty-five generation and on up to the fifty-five to sixty-five bracket. For four weeks members of each age group would go through a rigorous series of tests, similar to the ones conducted on astronauts, designed to reveal their ability, or inability, to withstand the special physical and mental demands of traveling in and from space. Though both sexes went through the same regimen, the attention was focused on the women who, for the first time in the history of the space program were really being tested seriously.

"When I stopped to ask myself why I wanted to do this so badly," Luthi recalls, "I realized that I wanted to find out whether I could endure those physical pressures and hardships that had challenged men but somehow never seemed to touch the sheltered lives of women." She had been a housewife for 20 years. "Now I was ready," she says, "to seize this opportunity at NASA to discover whether I really measured up physically."

Before the first female subjects arrived at the biomedical research facility, there was genuine excitement and anticipation about who the recruits would be. "We didn't know what kind of woman would volunteer," says manager Dee O'Hara, who has been flight nurse for NASA's manned space missions since the days of *Mercury*. "We thought it would probably be housewives, because they were the only ones with flexible enough schedules."

Actually they came from all walks of life. Bernice Robertson, fifty-five, for example, was chief of the children and youth unit of the California Department of Health. While she was driving to work at Berkeley, California, one morning, she heard on the radio that NASA was looking for adventurous women. "And at seven o'clock in the morning a *bed*-rest study sounded very appealing," she jokes.

Her job posed no problem. She was promptly granted a leave of absence and took some vacation days as well. Her husband, George, an administrator for an ambulance service, was another matter. "If you're going to be gone thirty days, who's going to cook for me?" he wanted to know.

Ever the dutiful wife, Robertson fixed up 30 meals, sealed them up individually, and popped them into the freezer. His meals then guaranteed, her husband became enthusiastic about her mission, so much so that he applied as a male subject himself. "We would have been the first couple," Bernice muses, "if he had made it."

It was twilight in Menlo Park, California, when Dale Graves returned home from the supermarket. She threw a steak on the broiler and settled into her teal-green swivel rocker to read a story about the space shuttle in the Palo Alto *Times*. A licensed pilot, a captain in the Naval Reserve, and a distinguished scientist at the Stanford Research Institute, she knew about the stories of female pilots who had taken the qualifying tests for astronauts and were mysteriously rejected. When she heard of the experiment, she called NASA.

Some women had problems, not in qualifying, but in bearing up under their families' unexpected resistance to their becoming NASA subjects. One of these was Arline Fitz[illegible]ld, a fifty-nine-year-old widow who was working as a court reporter for a municipal judge in San Francisco. She hadn't anticipated the strong opposition of her children. "They were dead set against it," she confides. "My daughter, who is a physician, knew enough about the procedures to be good and worried about my physical well-being." Her son was even more worried and adamant. "He told me if I was to go, he knew I would never come back," she says. But she applied anyway. "At my age you don't get many opportunities like this."

The women underwent an extensive screening process. "The only time I would actually discourage an applicant," says Lynn Dunham, who handled the phone queries at Ames, "was if someone asked me right out how much we pay. That signaled they were just looking for a job. And this is not a job, but a highly technical study." The pay, in fact, was only slightly above the minimum wage.

About half the women who called dropped out. Those who did make it to the interview were carefully rated for character, commitment, and even congeniality. "A little like the Miss America Pageant," Robertson observes.

The NASA interviewers wanted well-adjusted, interested candidates. "What we were looking for were mature, congenial women who seemed to have a real purpose in life," Dunham notes. The study was to be a group project, in which eight to ten women had to get along living together in cramped quarters for weeks. "You can't select a very nervous or egotistical individual. You can't choose someone who is a comic or a manic-depressive. Twenty-eight days confined with a woman cracking jokes or lying around with a chip on her shoulder can become very tiresome," Dunham explains.

Those who passed the selection process went on to the two weeks of grueling physicals and orientation. This would be followed by four to five spartan weeks of more tests and life without alcohol, cigarettes, caffeine drinks, or any medication — including vitamin pills.

"Some women were frightened by the physical demands and dropped out," says one who didn't, Donna Howell. She had retired from her job as an administrative secretary at age sixty-five. "It didn't faze me a bit." An outdoorswoman, whose pleasures include fishing and hunting with her husband on their property in Idaho, she plunged into the required physical with enthusiasm, and not a little apprehension, especially when asked to run the exhausting treadmill test. "It was the most intense physical I ever had in my entire life," she says. Once finished, however, she left for a relaxing vacation in Hawaii.

A few days into her trip she got a call from NASA to return for more tests. Even cutting short her holiday, she flew back to California. "I couldn't help wondering what I was letting myself in for."

Over the next two weeks she found out. Like all the women, Donna was spun around in a centrifuge to experience the crushing forces of gravity. She was dunked in a tank to be weighed under water, and she was wired from head to toe while her body was partly encased in a vacuum.

For some women it was traumatic, but for Dale Graves it was fun. "I enjoyed the other women so much and the challenge of every test. I knew I had to make it." Only eight to ten of the semifinalists in each age group would be selected after orientation.

At the end of the selection process the phones of the chosen women were ringing with a special message. When the call came to Arline Fitzgerald, she didn't answer. "I thought it was somebody bugging me for a transcript," she says. Late in the afternoon NASA telephoned again with the good news. She was accepted. "I had gin over ice with a twist of lemon to celebrate. I knew we'd have no alcohol for a whole month."

And so between April 13, 1977, and April 28, 1981, three different groups of women, between the ages of thirty-five and sixty-five — a total of 27 in all — reported to the NASA research center in Mountain View. They spent the next 28 days in virtual isolation. Like the passengers on future space shuttle trips, they were able to communicate with their families only remotely, in their case by telephone.

They were outfitted with biobelts that monitored their heart rate and deep body temperature. This involved wearing a small transmitter connected to an electrode and pasted over the heart. They also had to keep a rectal probe at all times. "Although we were aware of it — it isn't exactly natural — nothing hurt about it. The only problem was that it kept popping out," Graves says. The women also got their g-suits, identical to the ones that male astronauts wear, complete with their names imprinted over one breast pocket. "When you put it on, you couldn't help feeling a little closer to blastoff," Graves adds.

The women were under constant medical scrutiny as they went through a series of tests specifically designed to gauge the response of the female body to the stresses of space shuttle travel: changes in gravitational pressure, oxygen utilization, the effects of fatigue on performance level, and the stress of reentry. Their bodies were constantly being poked, stabbed, and tapped for various medical samples. Over the course of the study, for example, each woman had blood drawn from her arm 28 times. "Not at all pleasant," Fitzgerald says of the blood tests. "My veins got it so bad, they hid from the needle."

The women were often exercised to the point of exhaustion. In one phase of the test each woman lay on her back and rotated her feet, pedaling an exercycle overhead. "They made us work harder and harder," Graves remembers. "I felt like I was pedaling uphill."

In the performance simulator, they lay on their backs in a miniature cockpit, the instrument panel of an airplane spread out above their eyes. Experiencing the simulated turbulence of wind and rain, each woman was asked to take readings off the instrument panel while doing hand-eye coordination tests at the same time. "It was designed to test the effect of fatigue on performance capability," O'Hara says. Often it was scheduled after the women were exhausted from riding the centrifuge.

One of the stranger studies was the lower negative body pressure test in which the women lay in a cylinder, and the lower half

CONTINUED ON PAGE 128

HOUSEWIVES

CONTINUED FROM PAGE 67

of their bodies was encased in a vacuum, causing blood to drop down to their toes. "It felt as if you were two different people in the same body," says Luthi. "Half of your body was going up a mountain, and the other half was down at sea level."

But of all the studies and exercises, it was the centrifuge that was the most memorable and hair-raising test. Outfitted with the standard g-suit, each woman sat in a small cabin mounted at the end of a long centrifuge arm. The arm was sent spinning faster and faster to increase the gravitational pressure. They went from 1.5gs (one and a half times Earth's gravity) to 2gs, and all the way to 3gs, even though pressures of more than 1.5gs are unlikely for future space shuttle passengers.

"You're seated in this chair, tilted back, and wired with electrodes on your arms, legs, and temples," Luthi explains. "There's a radio in there with you and a microphone. The scientists are giving commands and asking you questions. You're told to stare straight ahead at green and red lights overhead, and when they turn one on, you're supposed to flick it off with a switch. That way they test your alertness. By the rate of your response, they could tell whether you were going to black out," she continues. "At any point you can stop the whole thing just by pressing a button, but I wasn't going to end it under any circumstances."

What did it feel like? "At 1.5gs there was almost no pressure on me," Luthi says. "At 2gs I began to feel some, and at 3gs I felt this great force, pushing me deeper into the chair. It was very, very uncomfortable. First I felt like I was going to be squashed, and then I began to feel as if the lower half of my body was swelling up. At that point I honestly would have preferred to be walking my dogs."

Some of the women felt sick to their stomach at the 3g level. Others passed out. But no one quit.

"I felt, in a way, like a piece of meat," Luthi continues. "I knew I simply was a body they were testing. It's not like you're being used as a sex object. You're at the center of what everybody is doing. It's not a bad feeling."

On the tenth day the women went into another phase of the study—bed rest. The deconditioning effects of zero gravity, scientists have found, can be duplicated by lying prone for long stretches of time. So for ten days the women were confined to bed. While they were bedridden, they were not allowed to raise their knees, to lean on their elbows, even for eating, or to sit up in bed. No one was permitted to walk to the bathroom. "And when we wanted to shower," one subject recollects, "someone would roll us in a gurney over to a special horizontal shower, lift us up onto it, and then turn on the water. We called it the car wash."

Passing the time was not as tedious as it might seem. There were television sets and radios, and plenty of lively gossip to catch up on. Some women knitted afghans. Others wrote letters. During the blood tests several women nearly passed out. "We were a lot more vulnerable," Luthi says.

There were some adjustment problems. The women developed agonizing backaches, but those disappeared as their bodies got used to the tedium of bed rest. More lingering were the aftereffects of their time lying down. All felt weak and a little dizzy when they were finally helped out of bed after the tenth day. Many experienced aches and pains, the result of a slight amount of calcium loss. This was especially true of the more physically active women like Howell. "This is what happened to the very active astronauts when they came back," she explains. "Their blood vessels enlarged from the inactivity, and they felt lightheaded with pins and needles in their legs—like I did for two days after it was all over."

The five-year study produced reams of invaluable data, which NASA scientists are still studying. NASA has not yet published a final report, but last spring, even as the final group of women were packing their suitcases to head for home at last, researchers were already drawing some preliminary conclusions. Immediately evident was that the 27 women had done a superior job, compared to the men, of adapting to the physical and psychological challenges of the series of tests.

Moreover, the women had quickly bonded together into a group that was more cohesive and much more supportive than anyone at NASA had anticipated.

No shuttle passenger flights are scheduled now. The time for fun and adventure rides into space may still be 20 to 30 years in the future, but when the time comes for frequent space travel, the sex of the traveler will present few problems. These 27 women proved that. Dr. Sandler confidently predicts it is just a matter of time before trips to space become as routine for women as they are now for men.

Ultimately the study served to reinforce what many people had claimed all along. As a creature of space, the woman is clearly the superior sex. As pilot and would-be astronaut Cobb suggested in her House committee testimony 20 years ago, women are better physical candidates because they consume less food and less oxygen and because they are more radiation resistant.

In addition, Sandler notes, "One of the real disadvantages women have here on Earth is a direct result of the force of gravity. Because of gravity, they need strength and stamina to do hard work. On this level they cannot successfully compete with men." But in the world of zero g the brute strength of men means little. Because strength isn't as important, and because of the women's superior performance in the Ames study, Sandler predicts, "In space, women are going to beat men." ○○

SICK IN SPACE

Aboard the shuttle you can't just lean over the rail—which is why scientists are searching for a quick fix for astronausea.

A small manila envelope bearing an ominous inscription is tucked into the pocket of my flight coveralls. I am hoping I won't need to open it, but I have reason to worry. The plane I am in, a military version of a 707, is used to familiarize astronauts with weightlessness, and over the years they have dubbed it the Vomit Comet. Its parabolic hops offer 25 seconds of free fall between brief onslaughts of twice normal gravity. With some 40 parabolas per flight, the ride can be a long one—especially if you are sick.

Two hours later, after I have floated in midair a total of 16 minutes, the manila envelope is still tucked neatly away. Weightlessness is so enjoyable, in fact, that I sign up for a return visit the next day. Yet for many who ride the Vomit Comet its name is well deserved. These days its passengers include physicians nearly as often as astronauts in one of the most intensive research efforts in the space program's history. The goal is to discover why four out of every 10 astronauts become motion sick during space shuttle missions.

Typically, the illness strikes an astronaut within 24 hours of lift-off, sometimes even in the first hour of space flight. The next two days can be uncomfortable, although astronauts maintain that their productivity is undiminished. Then, by the end of the third day, symptoms are usually gone. When Soviet cosmonauts are affected, they are given a chance to slow down for a few days until they have adapted to weightlessness. But shuttle mis-

sions are far too costly for NASA to add rest days and too hectic to reschedule such important tasks as releasing a satellite for one of the agency's paying customers. With this in mind NASA has put several teams of motion sickness experts to work on finding a cure.

"Motion sickness has probably been with us since man invented the wheel—or the boat," says Millard Reschke, a scientist with the Space Biomedical Research Institute at the Johnson Space Center in Houston. The symptoms of this age-old malady are familiar to many who have endured rough seas or turbulence aloft. A victim breaks out in a cold sweat and turns pale. He may begin to salivate, then swallow, and what is euphemistically called gastric awareness may set in. Waves of nausea assail the unfortunate traveler, and finally he vomits, often repeatedly. Yet this very ancient, unpleasant by-product of travel is poorly understood. The space-borne variety is even more puzzling.

Motion sickness in space was first reported among American astronauts during the *Apollo 8* moon voyage in 1968. Mission commander Frank Borman became ill on the outward leg of the trip. Back on Earth, Borman refused to undergo any tests for motion sensitivity, and NASA said only that he had suffered a reaction to sleeping tablets. As former astronaut Russell Schweickart puts it, getting sick in space "wasn't the right stuff." Most astronauts still don't like to talk about it.

Schweickart, who experienced motion sickness during his *Apollo 9* mission in 1969, spent the next four to five years studying the problem with researchers—with little success. "I suspect even today," Schweickart says, "the medical community does not understand even the most fundamental question: Why does motion disturbance result in a vomit reflex?"

Researchers believe that motion sickness stems from a complex interplay of sensors that report to the brain on motion. They have given most of their attention to the vestibular system, which allows us to feel movement, to balance, and to sense our body's position. The vestibular organs, nested in the inner ear, have two main components—the semicircular canals and otolith organs.

The semicircular canals are narrow tubes filled with fluid; each has a door-like flap that registers motion of this fluid. They report every twist and turn of the head. In engineering terms, they are angular accelerometers.

The small sacs called the otolith organs, also filled with fluid, tell us literally what's up. They are the body's linear accelerometers, registering the constant force of gravity. When you lean your head to one side, gravity tugs at a layer of calcium carbonate crystals inside the otolith, causing the crystals

As former astronaut Schweickart put it, getting sick in space wasn't "the right stuff."

to shift slightly. Even with eyes closed, you can tell that your head is tilted, and in which direction, by the signals from your otolith organs.

Together the semicircular canals and otolith organs allow us to keep our balance while executing complex motions ranging from walking up a spiral staircase to dancing a waltz. But they can be fooled and can disagree with each other as well as with our other senses. Pilots have flown out of fog banks believing they were right side up, only to learn from their eyes that they were upside down. Some sailors continue to feel the sway of the deck even when they can plainly see they are back on shore. And during a rough sea or bumpy air voyage the vestibular organs register sharp motions, while the eyes are reporting that things look fairly steady. As far as anyone knows, it is this stream of conflicting signals to the brain that causes motion sickness on Earth. The "sensory conflict" theory has been popular for decades.

In space, sensory conflict arises from the effects of weightlessness on the vestibular organs. The fluid in an astronaut's semicircular canals has inertia just as on Earth; this allows him to feel rotations. His otolith organs, on the other hand, no longer have the constant tug of gravity on their calcium carbonate crystals. The combination of normal canal messages with abnormal otolith input is a form of sensory conflict peculiar to space flight.

When Schweickart returned from *Apollo 9*, he headed for the Naval Aerospace Medical Institute in Pensacola, Florida, where a physician named Ashton Graybiel was leading the field of motion sickness research. Schweickart was spun in a rotating chair to gauge his sensitivity to motion sickness. His ears were flooded with warm and cold water to induce the erratic eye motions called nystagmus that are associated with severe motion disturbances. And he rode again and again on the Vomit Comet, all so that some clue might emerge to why he was prone to motion sickness. There was none. In fact Schweickart was judged relatively resistant to motion sickness.

Today, 15 years since Schweickart began working with Graybiel, there is still no way to tell who will experience space sickness. Graybiel is still at work on the question, aided by his son-in-law, James Lackner of Brandeis University. Part of the problem, Lackner believes, is that sensory conflict involves more than just the inner ear. When you turn your head, sensors in the neck muscles are activated. Their data are processed in the same part of your brain as the messages streaming in from the vestibular organs about your head's motion and from your eyes on the changing field of view. In normal gravity, these different sets of data give you a consistent picture of the turn.

Still more information pours in from other sensors throughout the body. If you move your arm, your brain determines its position by processing data on the tensions of the arm muscles. When you sit down touch receptors in the skin sense the pressure of the chair. And you register pressure on the soles of your feet every time you stand up.

None of this information, which neurologists call the proprioceptive, is available in weightlessness. Muscles no longer fight against gravity. Nothing presses against a free-floating person. Astronauts have reported awakening from sleep in a darkened cabin and not being able to tell where their arms were.

In the absence of gravity, with the otolith organs unable to sense up and down and the proprioceptive inputs removed, an astronaut has only one means of sensing orientation — vision. If he never strayed from his spacecraft couch, that might not matter. But once floating free, he is more likely to align his sense of up and down with his body, no matter what the orientation of his surroundings. Lackner has even found on the Vomit Comet that a subject can change his sense of orientation drastically just by looking in certain directions — upwards as opposed to at his feet, for example.

So diverse are the various stimuli involved in this orbital variation of Earthbound sensory conflict that NASA stopped referring to space motion sickness and coined a new term, "space adaptation syndrome."

Lackner is the first to admit that 15 years of research have not brought him and his few dozen colleagues much closer to understanding space adaptation syndrome. He rides the Vomit Comet several times a year, along with his test subjects, but wishes it were possible to carry out his work in the cabin of the space shuttle. For the time being, he and other scientists in the field must rely heavily on another researcher who has that chance: William Thornton.

As an astronaut and physician, Thornton was the right man in the right place in late 1982, when NASA's concern over space sickness was at a peak. During the fifth shuttle flight, that November, astronaut William Lenoir's bout with motion sickness had delayed a spacewalk attempt, and the press gave the problem a great deal of attention. Despite Lenoir's postflight assurances that his work capacity was undiminished by the illness, the military was beginning to wonder if it could successfully use the shuttle to deploy its reconnaissance satellites on short notice. There was talk of a five-year research effort costing tens of millions of dollars. But the agency could not afford to wait for such a program. So shuttle planners added Thornton and fellow physician Norman Thagard to upcoming flight crews specifically to figure out what was making the astronauts ill—and how to stop it.

For Thornton it was the start of months of 20-hour days developing the instrumentation he would take with him on the shuttle's eighth flight, in August 1983. Some of the experiments would also be ready for Thagard to bring along on the seventh mission in June for valuable preliminary data.

When Thornton talks about space sickness, it is with a directness that sets him apart from other astronauts—and his approach to the problem is unique among researchers. "My interests are

One crew member threw up after noticing the Earth at an odd angle through the windows.

operational ones," he says flatly in his easy North Carolina drawl. "If I could find some new aspirin tablet that would cure this thing, and nobody knew why, I'd be the happiest man on Earth. I'd fold up my tent and go away."

NASA would like to see Thornton succeed, for the drugs most often tried against space motion sickness have been only partially effective. While Graybiel was extending the sensory conflict theory to weightlessness in the early '70s, he hit on a drug that had unprecedented success with his test subjects in preventing motion sickness both in normal gravity and in parabolic flight. It is scopolamine, an ingredient found in some cold remedies. No one knows why it works. It may block the chemical transmitters by which the vestibular system communicates with the brain, thus blocking signals of sensory conflict. Part of the ambiguity stems from the fact that these transmitters have yet to be identified.

But scopolamine has some undesirable side effects, among them drowsiness. For astronauts, Graybiel added the stimulant dexedrene, although space shuttle commanders, who would have to land the shuttle if a launch were aborted, are prohibited from taking the drug until after reaching orbit. A number of astronauts on the first five shuttle flights took scop-dex capsules before launch, with mixed results. "There isn't really enough data there to say anything about it yet," Reschke says. "But there is every reason to believe that it will be effective." But because of its side effects, it is unlikely that NASA would stick with scopolamine if something equally effective came along.

To Thornton, the effectiveness of scopolamine on the ground, on which Reschke's optimism is largely based, is beside the point. Space motion sickness, he says, is wholly unlike its Earth-based counterpart. Researchers have been severely limited, he feels, because "they used traditional methods of making people sick and tried to extrapolate from that. If you think you can produce the effect by putting somebody in the chair and making him sick, you are badly deluded."

Before his own mission, Thornton interviewed fellow astronauts upon their return from space; their comments reinforced his feeling that something unique was happening. Many of the hallmarks of ordinary motion sickness—sweating, pallor, and even nausea—were frequently absent. Loss of appetite and a knot-in-the-stomach feeling were often present. And curiously, they reported, when they vomited it was often without warning. One crew member threw up suddenly after noticing the Earth at an odd angle through the shuttle's windows.

From this information Thornton suspected the digestive tract was somehow affected by weightlessness, and he added abdominal studies to his growing agenda for the August flight. When Thagard lifted off on his mission, the schedule included a request from his fellow astronaut. "I asked Norm to look carefully at the stomach, and he did," says Thornton. "He also took the time to listen." Why listen to the stomach? In a normal person on Earth, the digestive tract is in near constant motion; it can be heard with a stethoscope. Thagard returned with some important news: When his crewmates were ill, their digestive tracts were quiet.

That could explain why vomiting sometimes comes on so suddenly, Thornton reasoned. With the normal digestive motions ceased, the stomach would eventually fill up. Then it would send distress messages to the so-called emesis center of the brain, where the vomit reflex originates. With loud distress calls already pouring in from the confused vestibular organs—due to the canal-otolith sensory conflict—the first message from the stomach would push the emesis center over the edge—perhaps too quickly for nausea to set in. This is in strong contrast to vomiting on Earth, in which the stomach sends no such "trigger" signals to the brain.

When Thornton and five crewmates left Earth on August 30, 1983, Thagard's results were very much on his mind. But Thornton had developed another theory about what he would find. In zero gravity the body's fluids migrate headwards, which makes astronauts' faces puffy after a few days in orbit. Thornton felt that fluid would probably build up in the inner ear, causing a condition similar to Meniere's syndrome, whose victims experience dizziness, nausea, and vomiting. It might well be this fluid buildup that causes space sickness, he reasoned.

As soon as *Challenger* reached orbit, Thornton was at work. "I learned more from the first hour and a half in space," he said after his return, "than from all my literature searches." While his crewmates attended to their flight plan, Thornton, wired with electrodes on his eyes and skin, labored under his own hectic schedule. He barely stopped to eat. He seemed to move from one test to another in a blur of wiring and electronic gear that reminded the others of "an explosion in a Heathkit factory." When the five days were up, Thornton had changed his mind in a big way.

"I had to eat a lot of crow," Thornton admitted. "I had been opposed to calling it motion sickness. I am now willing to say that it is a form of motion sickness, but vastly different from anything experienced before." Thornton could speak as much from personal experience as anyone. NASA regulations prohibit him from disclosing individual symptoms, even his own. Reportedly, however, he felt the rapid onset of motion sickness early in the flight as he moved about within *Challenger*'s cabin. Confirming what Lackner had discovered during parabolic flight, Thornton found that nodding the head up and down is particularly sickening.

When Thornton had time to examine his data, there were more surprises. His tests disclosed no signs of fluid buildup in the inner ear, as he had theorized. There was no evidence that vision was distorted. No overwhelming signs emerged that lack of proprioceptive information played a decisive role; devices designed to induce the normal muscle tensions felt in one g had no ef-

fect. (Reschke, however, wonders if, later, more precise measurements than Thornton was able to perform might change some of these results.)

Interestingly, Thornton learned as much from his stethoscope as from his "Heathkit factory." One of his most informative activities was conducting in-flight physical examinations of his crewmates. These confirmed Thagard's findings of a quiet digestive tract. Thornton was prepared: He had brought along a drug to set the digestive tract in motion again. Though Thornton isn't telling for now, the drug is probably related to metachlopramide, which is commonly used for such purposes. Crew members who took it during motion sickness got quick relief from nausea, they didn't vomit again, and their appetites came back.

Some symptoms—headache, general malaise, and sensitivity to such motions as nodding the head—persisted. A truly successful "operational solution" will have to cure these symptoms as well. What's more, astronaut Byron Lichtenberg, himself a motion sickness researcher, later tried the drug during the first Spacelab mission last fall, with no benefit at all. Still, for the crew on Thornton's flight, the digestive drug appeared to eliminate one of the most unpleasant—and, for spacewalkers, one of the most hazardous—effects. "It's not a complete cure," Thornton says, "and it remains to be proven. But it may be an important breakthrough."

Thornton will have a chance to continue his work in space late this year when he will fly again on the shuttle, this time with the roomy Spacelab module along for extensive research. While he tries to confirm the success of his digestive drug and nail down the "operational solution," earthbound researchers like Lackner will continue working for a broad and fundamental understanding of the problem.

"The more you pick at it, the more complicated it is," Lackner says wistfully. It may be a decade or more before he and his colleagues find what they're after, and by that time NASA's proposed permanent manned space station could be operating. With astronauts spending six straight months in a weightless environment, Lackner reminds us, motion sickness will be only one of a host of complex physiological problems encountered, including radiation exposure, potential weakening of heart muscles, and Lackner's own special interest, reflex and coordination problems due to prolonged weightlessness. "That's why my world won't end when space sickness is solved," he says. "It's just going to start."

Andrew Chaikin, an editor of Sky and Telescope, *writes regularly about the shuttle program and planetary exploration.*

Space Travel Is No Joyride

BEHAVIORAL METHODS MAY ALLEVIATE SOME OF THE DISCOMFORT THAT ACCOMPANIES WEIGHTLESSNESS.

BY CHRISTOPHER JOYCE

Reproduced with permission of the copyright holder from Joyce, Christopher. Space travel is no joyride. Psychology today, v. 18, May 1984: 30, 32, 34-37. Reprinted from Psychology Today Magazine (c) 1984 (APA).

If NASA were to choose you to ride the space shuttle, the chances are almost 50-50 that one of your first experiences in space would be throwing up. Many astronauts have, although NASA doesn't like to talk about that since some crew members find it embarrassing. And along with that upsetting factor there are other undesirable effects of weightlessness—lethargy, lack of appetite, drowsiness, stomach awareness, malaise, cold sweat and nausea. These are part of "space adaptation syndrome," or space sickness, the number one medical concern of space agencies of both the United States and the Soviet Union.

Behavioral and biomedical scientists at NASA have always been intrigued by the effects of weightlessness on the human nervous system, much to the chagrin of those astronauts who'd rather just fly than play orbiting guinea pig. But now that NASA plans to build and permanently man an orbiting space station by the early 1990s, solving the mystery of space sickness has taken on a new urgency. Not only will men and women be in space for unusually long periods, many will be shuttling to and from orbit for brief periods that won't allow them time to adapt to weightlessness.

Astronauts are a "gritty" bunch, says one scientist who has worked with them and once applied to be one. That is, they grit their teeth and get on with their work, smiling for the cameras while bobbing like bubbles in a lava lamp. But space sickness has played havoc with work schedules on at least two shuttle flights. During the third shuttle journey, much of the third day's schedule was pushed back because both crew members were sick. During the first few days of the Spacelab flight last December, experiments on crew members already woozy from moving around in zero gravity made them ill, and tight schedules were again disrupted.

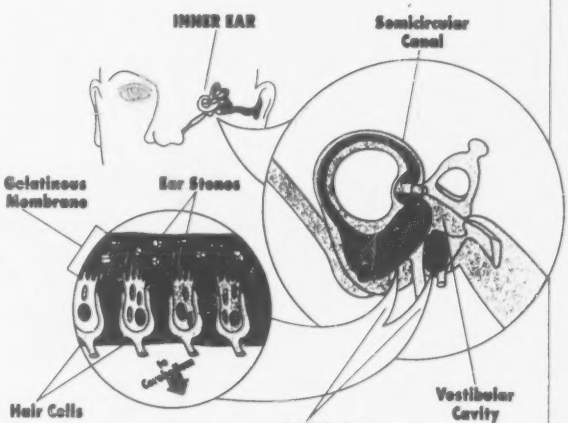
NASA can't afford to have astronauts suddenly calling in sick from 150 miles up, so a laboratory dedicated to the study of space sickness is being

Bruce McCandless II, outside the Challenger.

IT'S IN YOUR EAR—YOUR INNER EAR

The inner ear's vestibular cavity is the point of entry for the signals that tell us where we are and how we move. Linear motion and the constant force of gravity are sensed by the inner ear's otolith ("ear stone") organs, which contain calcite crystals that lie like a carpet on a sensory membrane in the labyrinth of the inner ear. If you sit motionless, the otolith registers gravity alone; linear movement (forward, backward or up and down) and acceleration cause the crystals to shift and move the hair cells on which they sit. These send signals to the cerebellum and brain stem, which perform the complex job of making sense of these signals.

Another element of our internal guidance system consists of three tubes in the inner ear called the semicircular canals. These narrow pipes contain fluid that moves through the canals when you rotate your head, and signals rotational or angular movement. —*C. J.*



NINA WALLACE

set up at the Johnson Space Center near Houston. Eventually, researchers hope to discover how weightlessness warps one's perceptions of position and motion and causes space sickness. In the meantime, psychological remedies, such as biofeedback and relaxation therapy, are promising candidates to augment the powerful but unpredictable drugs usually given queasy crew members.

The study of space sickness is so new—fewer than 150 people have flown in space—that researchers have just begun to track down its causes. One early hypothesis, popular among Soviet scientists, was that the upward shift of body fluids during gravity-free flights might be the culprit. That theory gave rise to cumbersome "negative pressure" suits cosmonauts wore over the lower body to draw blood back down to where it belongs. Scientists have abandoned that notion, however, and have decided that space travelers suffer from the same malady that laid low Lord Nelson, Napoleon and, astride his "ship of the desert," Lawrence of Arabia—motion sickness.

Space sickness is now believed to be an attack by the senses on the body's motion-control mechanisms, located primarily in the vestibular organs in the inner ear (see box). Much of the research on space sickness has been done at the Massachusetts Institute of Technology's Man-Vehicle Laboratory. There, in a veritable chamber of scientific horrors, researchers spin, rotate, drop and otherwise confuse subjects, who get sick and then adapt. Associate director Charles Oman should know the symptoms when he sees them: He is a veteran of offshore sailboat racing and has seen his share of pitching decks and bouts of what Australian sailors call "laughing at the ground."

BIOFEEDBACK AND RELAXATION THERAPY MAY AUGMENT THE DRUGS USUALLY GIVEN QUEASY CREW MEMBERS.

"When you move your body, the brain has learned what sensory signals to expect from the vestibular organs," Oman says. "It compares the expected to the actual. When it sees a difference, it says to itself, 'Ah, something new here,' and it triggers corrective movements." In space, however, the inner ear's otolith organs are confused by what they sense because they miss the effects of what has been their constant companion since birth—gravity. Meanwhile, the semicircular canals still sense rotational rolling and pitching head movements accurately, since their perception isn't affected by gravity, but what they sense doesn't agree with what the otolith organs sense. As a result, Oman explains, the signals sent by the vestibular organs to the brain do not match the blueprint drawn on the basis of earthbound experience. In short, what you see is not what you get.

The result is space sickness. At first, there may be a dizziness. Soviet cosmonauts recall feeling as if they had been turned upside down. As the

C. Gordon Fullerton floats in zero gravity: The body can't tell up from down.

space travelers unstrap and move about the cabin, they turn and move their heads, which generally brings on the more serious symptoms, nausea and vomiting. NASA's scientists have observed that rapid head movements are the surest way to create space-motion sickness; their observations are borne out by the increasing frequency of this sickness as space vehicles grow larger and give the crew more room to move about. This was especially true during the first flight of Spacelab, when the crew had to move around the cabin a lot, setting up the lab and various experiments. This extra movement, early in the flight, may explain the sickness some crew members experienced.

Why the nausea and vomiting? One possible explanation is that when the inner ear's vestibular system is overloaded or confused by weightlessness, there is a spillover that affects the brain's nearby vomiting trigger zone. Kenneth E. Money, a physiologist with Canada's Defence and Civil Institute of Environmental Medicine, proposes another theory: The brain receives mismatching information when poison enters the body. It responds by inducing nausea and vomiting to get rid of the poison. Since space sickness also yields mismatching information, the brain responds to it in the same way.

THE CONTRADICTIONS CREATED BY MOVING AROUND IN ZERO GRAVITY ARE UNRELENTING.

In space, the vestibular organs get no relief: The contradictions created by moving around in zero gravity are unrelenting. Were it not for the brain's flexibility, space flight might be as arduous for astronauts as ocean travel was for Charles Darwin, who never overcame seasickness during his voyage aboard the Beagle and who wrote as eloquently of his suffering as he did of Nature's exotic creations.

Fortunately, according to Oman and Larry Young, director of the Man-Vehicle Lab, the brain learns to compensate: It either ignores or, more likely, reinterprets signals from the otolith organs and puts more trust in the visual input it receives. Oman cites seasickness to illustrate this idea: Below deck, with no visual cues to prepare you for the pitching of a boat, you suffer more from your perplexed vestibular system than you do on deck. For much the same reason, pilots and automobile drivers, who are in control of their vehicles and therefore generally know what to expect, don't usually get motion-sick; their hapless passengers do.

Young, Oman, Money and Canadian researcher Douglas Watt tested these hypotheses on the crew of Spacelab during an ambitious investigation of space sickness. They had the help of one of their former students, Byron Lichtenberg, a biomedical engineer who earned a degree at MIT studying the vestibular system and then won a seat aboard Spacelab.

Young's so-called "dome" experi-

ment requires an astronaut to peer into a rotating drum that fills the field of vision with rotating spots. On Earth, this creates the uncanny sensation that you, the viewer, are rotating in the opposite direction, or that the room is spinning, much the same way you feel if you whirl around like a dervish and then stop suddenly. On Earth, the vestibular organs, which aren't actually in motion, don't corroborate this induced sense of body movement and thus help damp the sensation. Things work differently in space.

The "completely unexpected" finding in space, an excited Young told reporters at mission control in Houston, was that the sensation of rotating was grossly exaggerated aboard Spacelab, suggesting that the vestibular system had difficulty damping the sensation. Young stresses that his findings are still preliminary, but he argues that in space the brain may learn to rely less on the vestibular system and more on visual stimuli. If this is the case, then adaptation to weightlessness occurs because the brain gradually stops listening to the confused vestibular system and begins to rely more on the visual system.

Once acclimated to weightlessness, most space travelers aren't troubled by motion sickness, as those films of astronauts performing seemingly endless somersaults testify. But another familiar picture from space lore—that of beaming crewmen disembarking from another long flight, kicking the shuttle's tires and waving to the crowd as if they'd merely driven around the block—is simply false.

ADAPTATION TO WEIGHTLESSNESS MAY PERSIST AFTER LANDING AND CREATE EARTH SICKNESS.

Reports from the Soviet Union tell of cosmonauts who, after several months in space, had to be carried from their spacecraft; their cardiovascular systems, adapted to weightlessness, couldn't support the strain of gravity. Scientists are also finding that the vestibular system's adaptation to weightlessness may persist after landing and create, in some cases, "Earth sickness."

At NASA's Dryden flight-research center in California, the Spacelab astronauts were closeted from public view for several days as scientists watched their readaptation to gravity. "We saw some very interesting and bizarre postflight sensations," Young reports. Gazing into the dome, one crew member felt as if his body had tipped forward 90 degrees and were rotating like a pig on a spit. Others had trouble turning corners cleanly or saw the Earth spin when they jerked their heads. Some who had easily performed a "rail test" (walking with eyes closed along two narrow rails) before the flight fell off the rails after returning from space, buttressing Young's notion that the eyes had become more important, relative to the vestibular system, in the astronaut's sense of balance. "It isn't until you do fine tests that you see that they (the returning astronauts) are not really in such good shape," Young concludes.

Perhaps most dramatic was Money's postflight test in which astronauts were taken up in a KC-135 military transport and re-exposed to weightlessness during short parabolic flights. Violent head movements that made some of them ill before and early in their Spacelab voyage now had no effect, suggesting that the brain was still stuck in zero-gravity gear. The more time spent in weightlessness, the more difficult readaptation is; indeed, some Soviet cosmonauts have been ill for days after long flights.

Adaptation to weightlessness takes time, and this can cause problems in space, especially on short flights. "We

are beginning to pay a lot more attention to the degradation of performance caused by space-adaptation syndrome," says Jerry Homick, who has managed NASA's space-sickness research program, now at about $4 million a year, for the past decade. What's needed is a way to prevent or at least lessen the effects of space sickness early in the flights. NASA has thus far relied mostly on drugs, especially a mixture of scopolamine and Dexedrine. Scopolamine is a common anti-motion sickness drug. Dexedrine is added to counteract its soporific effects. Homick considers drugs an imperfect solution because their side effects can impair performance.

A more controversial but perhaps more promising antidote to space sickness is biofeedback coupled with "autogenic training." Patricia Cowings, a psychophysiologist at NASA's Ames Research Center near Palo Alto, California, pioneered the use of this technique with astronauts. Cowings is known affectionately to the astronaut corps as "The Baroness of Barf" ("I guess that's a compliment," she says), a title she earned by making people sick so she could learn how to make them well.

"Back in 1973, NASA knew it had a problem. Biofeedback was thought to be 'mystical,' but they were willing to try anything," Cowings recalls. Because astronauts' training time is precious, NASA told her to come up with a program that would take no longer than six hours. During this time astronauts were supposed to learn to control the physiological symptoms associated with space sickness and thereby control the sickness. Cowings designed a program of 12 half-hour sessions combining autogenic training—"a series of self-suggestion exercises, or a method of getting people to focus attention on a part of their body"—with biofeedback. During autogenic training, she teaches a subject to mentally evoke a sensation, like warmth in a limb or relaxation of muscles, to bring about desired physiological changes such as increased skin temperature or relaxed muscles.

Cowings' brand of biofeedback involves learning to control as many as 20 physiological functions related to motion sickness. These include such things as heart rate, skin conductance, depth and rate of respiration and the flow of blood to the hands. Subjects learn to regulate these autonomic functions by watching them as they are displayed numerically and on an oscilloscope. Cowings uses auditory tones to tell subjects when they begin to lose control of a particular function, or simply tells them herself. "The ex-

perimenter is like an orchestra conductor," trying to focus a subject's autogenic abilities on those autonomic functions that normally react first to motion, Cowings explains.

After the first four sessions, a subject rides a rotating chair to see if he has improved his control of the symptoms. Then it's back to the feedback machine. In the course of the program, subjects learn to manage the symptoms without feedback data and under distracting conditions; eventually they can control body functions crucial to motion sickness under trying circumstances, such as those aboard a spacecraft.

During the third flight of Spacelab, scheduled for November, three astronauts trained by Cowings will test her method, which has worked well on the Earth. For several upcoming flights, Cowings will dress her subjects in what she calls "the latest in astronaut underwear" and record several of their autonomic functions. The astronauts will also have biofeedback units strapped to their wrists, so they can monitor themselves.

Leonard Gardner, a clinical psychologist at the Johnson Space Center, is another believer in the behavioral approach to curing motion sickness. At the Air Force School of Aerospace Medicine in San Antonio, Texas, Gardner showed skeptical officers that he could salvage flight-training washouts, who had failed all other attempts to control their air sickness. Gardner trained 50 air crewmen in biofeedback and autogenic techniques and succeeded in returning 44 of them to active flight training.

Gardner's approach differs from Cowings'; he hooks his subjects to biofeedback equipment while they are spun in rotating chairs. In the early stages of his two-week session, the pilots were encouraged to take their minds off what they were doing. "One guy remembered practical jokes he had played on people," Gardner recalled. "He'd be up there in the chair, smiling and chuckling away. And after he had finished, he'd come down and say, 'Hey, what happened up there?' " Gradually, the subjects dropped the "thinking-good-thoughts" technique and instead concentrated on slow, diaphragmatic breathing.

"Many people are skeptical about behavioral training," Gardner remembers. "They say, 'This stuff isn't supposed to work,' and a lot of people, the 'I-eat-nails-for-breakfast' type, look on people with motion sickness as being weak. We encountered a lot of squad commanders with this attitude." Nor are pilot trainees the best subjects; Gardner says most of them are aggressive, proud and ambitious. "These people are usually uncomfortable with relaxation training," he points out. "Many of them never know how to relax. Their response has been to try harder and grit their teeth," just the wrong thing, he says, for combating motion sickness.

But the era of the gritty test pilot in space is ending, and NASA will need a broad range of expertise to build a permanent station. Clearly the human mind and body can function in weightlessness, but travel in space can have its side effects. Now that space travelers are performing complicated tasks, rather than simply being research subjects or "monkeys in a can," space sickness may prove to be a serious obstacle. As NASA and the Soviets contemplate colonies on the moon, and perhaps extended travel beyond, psychologists will become as important as engineers and physicists in preparing humans for the ultimate frontier. ☐

F. PLANETARY EXPLORATION

Mission to Mars: The Case for a Settlement

Reproduced with permission of the copyright holder from Stoker, Carol and Christopher P. McKay. Mission to Mars: the case for a settlement. Technology review, v. 86, Nov.-Dec. 1983: 27-30, 35-37.

BY CAROL STOKER AND CHRISTOPHER P. McKAY

The time has come–again–to plan for manned expeditions to Mars. Had a NASA mission begun as suggested for November 1981, these astronauts would have returned to Earth this past August.

HISTORY will undoubtedly record the Apollo moon landing in 1969 as one of humanity's greatest achievements. That journey was a giant step forward for humankind, proving that we could explore space and expand beyond our home planet. The ensuing 15 years of sustained activity in space have totally changed our perspectives of this frontier. It now seems obvious that people will live in space, but questions remain on when, what we will do there, and how we will get there. We must decide what the next step will be.

Over the last two years, a grass-roots organization of planetary scientists and engineers has made a case for establishing a permanent settlement on Mars as the next major initiative in space. Sounds bold? So did the moon landing a generation ago. In many respects, the incentives for a Mars settlement are the same.

In the future, as in the past, the nations that explore and expand the new frontier will be preeminent. A permanent settlement on Mars would provide a focus for developing space and help stake the U.S. claim to that frontier. It would assure the country a dominant role in deciding how people develop and utilize the solar system, whether by mining mineral-rich asteroids, manufacturing products in the microgravity or vacuum of space, defending national interests, or broadening scientific understanding. Settling Mars would give the United States a strong voice in shaping space law and treaties and guarantee its international prestige.

Why Mars? Public fascination with the Red Planet is legendary. From Percival Lowell to H.G. Wells, turn-of-the-century writers so vividly described life on Mars that lay readers assumed that an advanced civilization lived there. Much of the speculation was fueled by the Italian astronomer Giovanni Schiaparelli, who published many detailed maps of Mars in the 1890s. Among the features he described were straight lines connecting darker regions across intervening light areas. Schiaparelli called these markings *canali*, or channels, which became the famous "canals" of Mars when translated into English.

CAROL STOKER is a research associate in the Laboratory for Atmospheric and Space Physics at the University of Colorado in Boulder. Beginning in January, she will be a fellow in the Advanced Study Program at the National Center for Atmospheric Research in Boulder. CHRISTOPHER McKAY is a National Research Council fellow at NASA Ames Research Center in Moffett Field, Calif. The authors were coorganizers of the Case for Mars conference in 1981 in Boulder.

As rocket technology developed, the dream of reaching Mars entered the realm of possibility. For space pioneer Robert Goddard, the exploration of Mars was a long-held goal, and Wernher von Braun, the architect of the Apollo program, viewed the lunar landing as the first step toward a manned flight to Mars.

Of all the planets, Mars is the most hospitable and similar to Earth. Mars is the only other planet in the solar system with both an atmosphere and an accessible surface. Mercury has no atmosphere and is too close to the sun to permit human habitation. The surface temperature on Venus is 460°C—above the melting point of lead and much too harsh to allow a manned landing. By contrast, temperatures on Mars range from -120°C on polar winter nights to a high of 20°C in the southern hemisphere in summer. Unlike the giant planets Jupiter, Saturn, Uranus, and Neptune and their moons, Mars is close enough to Earth for people and materials to reach it within nine months, a reasonable time.

Unlike the moon, the only other candidate for a settlement, Mars is abundantly endowed with all the resources necessary for developing a self-sufficient base. Absent on the moon, water occurs in small quantities in the martian atmosphere and soil and in large quantities in the polar caps. Water is the most important compound needed. In addition to sustaining life, it is a source of hydrogen atoms, which are needed for chemical fuels, including rocket fuel, as well as for building materials and other useful compounds.

Mars also has the resources to produce life-support materials such as air, food, fuels, fertilizers, and building materials, eliminating the huge cost of transporting them from Earth. Although the martian atmosphere is thin—only 0.6 percent of the sea-level atmospheric pressure on Earth—and is mostly carbon dioxide, it can be processed to obtain oxygen to make breathable air. The atmosphere also contains argon and nitrogen, which may be used as a buffer gas in breathable air to inhibit combustion. Martian soil is 40 percent chemically bound oxygen, an-

other potential source of this important element. The soil also contains sulfur and chlorine as well as the metals sodium, magnesium, and iron. Thus, construction materials, fuels, and soil for growing plants can be manufactured on the planet.

In addition, Mars holds such a strategic position within our solar system that it may one day be regarded as the St. Louis of space. Mars is the gateway to the outer solar system and the main belt of asteroids between Mars and Jupiter. Asteroids are solar-system debris that were not incorporated in the formation of the planets. Some are rich in iron, nickel, and possibly other elements that are relatively rare on Earth. Other asteroids may be rich in volatile compounds such as carbon, oxygen, and hydrogen that can be used to make breathable air and fuels for future space-based operations. The two moons of Mars, thought to be asteroids captured by the planet's gravitational pull, could be critical proving grounds for asteroid mining techniques.

For scientists interested in planetary evolution, Mars remains a source of fascination. Despite the experiments performed by the Viking mission in 1976, the question of whether life exists on Mars has still not been completely answered. Even if contemporary life forms are absent, perhaps life evolved in a past, more hospitable climate. Mars offers a rich field for planetary biologists to explore.

Over a decade ago, NASA actively studied and planned a manned mission to Mars. The idea lost support when the agency's funding was cut back, but it is now drawing renewed interest. George Keyworth, the president's science advisor, recently suggested that it was time for the United States to think about new directions for the space program as ambitious and bold as the Apollo program. A Mars settlement would certainly qualify. Moreover, establishing a long-range goal for the space program would help ensure continuity in funding and widespread popular and political support. Such continuity has been sorely lacking in the U.S. program over the past decade.

Given recent advances in technology, a single manned mission could be staged for one-half to one-third the cost (in 1981 dollars) of the Apollo program. Such a mission would make use of the space shuttle and the proposed space station, projects that top NASA's priority list. With these and other projects under development, the Mars settlement is within reach of today's technological capabilities. Given a firm national commitment, we could be there by the beginning of the next century.

Scouting the Planet

The first step in planning a martian settlement is to investigate the planet's natural resources. Although the 1976 Viking mission to Mars returned a wealth of data about the planet, scientists lack the detailed information necessary to select a site for a permanent base. Such a site must be close to water, fuels, minerals, and building resources and situated so that reliable communications can be established with Earth. The site must also be close to scientifically interesting regions, and be flat and solid enough for a spacecraft to land.

Although water, a key resource, is present on Mars, it is scarce compared with Earth's supplies. The only large known sources of water are the polar caps, but they are not ideal locations for a manned base because of extremely low temperatures and constant darkness during winter. However, scientists believe that large reservoirs of underground water in the form of ice or permafrost may extend to Mars' lower latitudes. The small amount of water vapor in the atmosphere—0.3 percent—is also a potential source of water.

The surface of Mars can be mapped for water and mineral resources at low cost with a spacecraft that orbits the planet's poles. NASA has already designed such a mission, called the Mars geoscience/climatology orbiter. It carries a gamma-ray spectrometer—an instrument that records emissions from radioactive isotopes and from the interaction of cosmic rays with atoms in the planet's surface soil to determine its composition. Atmospheric water vapor will be measured by detectors tuned to look at the infrared emission and absorption features of water. NASA estimates that the mission will cost $100 million—by comparison, the Viking mission to Mars cost over $2 billion. Costs will be low because the experiments take advantage of technology developed for other missions, and because the spacecraft itself is based on production-line satellites for orbiting Earth.

Once prospective base sites are identified, samples of martian soil should be collected and returned to Earth for analysis. Samples could be obtained by unmanned vehicles or by a temporary manned lander, just as lunar samples were collected. Scientists can analyze these materials on Earth and then devise manufacturing processes to take advantage of them so that initial manned missions can begin manufacturing immediately.

The natural resources available on the two martian moons, Phobos and Deimos, deserve attention as well. If the moons are asteroids, then they may contain valuable, even rare, minerals unobtainable on the surface of Mars. Dr. S. Fred Singer, professor of environmental sciences at the University of Virginia, suggests establish-

ing a manned "beach-head" on one of the moons before attempting a landing on the planet. From this base, astronauts could operate a fleet of remote-controlled rover vehicles to collect soil samples from Mars. One advantage of such a plan is that it avoids contaminating Mars with terrestrial organisms and Earth with martian organisms—if they exist.

Outfitting the Ships

The trip to Mars would use both the space shuttle and NASA's proposed space station for a transportation network. A manned space station in low-Earth orbit with facilities for building structures in space is a key intermediate step on the path to Mars. The size and complexity of spacecraft needed to build the Mars settlement will make it difficult if not impossible to launch them preassembled from the ground. Instead, spaceships will have to be assembled at the space station from components delivered by the shuttle. NASA expects to have the space station operating in the 1990s.

Both manned ships and unmanned cargo ships could be used in a voyage to Mars. Manned ships, which must support a crew over a nine-month flight between the two planets, will require heavy, complicated, and expensive habitation and life-support equipment. Everything not absolutely necessary for the crew on the Mars transit could be sent ahead on unmanned cargo vehicles, which can be relatively simple and inexpensive.

The choice of a propulsion system will affect the designs of both manned and unmanned vehicles. Conventional rockets launched from the surface of the Earth use chemical propellants, frequently combining liquid oxygen and liquid hydrogen to produce a powerful thrust. This is the only propulsion technology that has been adequately tested in space that has enough thrust to overcome gravity at Earth's surface. However, it consumes large amounts of fuel, posing problems for a long interplanetary flight. The fuel for the return trip must be carried on board, which further increases the weight of the vehicle and raises its fuel requirements. For each ton of fuel needed for the return trip, 5 to 10 tons of fuel are needed to boost this extra propellant to Mars.

More efficient propulsion systems would reduce the fuel costs of exploring Mars. The solar sail is an attractive possibility for propelling the unmanned cargo vehicles, which can travel slowly. Solar sails, first proposed by Russian researchers Konstantin Tsiolkovsky and Fridrikh Tsander in the early 1920s, use no rocket engines and expend no fuel. Instead, photons radiated from the sun strike a sheet of shiny material such as aluminized plastic film to provide the thrust. The sail must be one to two kilometers on a side to gather enough sunlight to create reasonable propulsive force. The World Space Foundation (WSF), a private research and development organization in Pasadena, Calif., has designed a solar-sail-propelled vehicle and plans to launch a prototype by 1987.

Robert Stachle, an aerospace engineer with NASA's Jet Propulsion Laboratory and president of WSF, has outlined a mission to Mars using a fleet of remote-controlled solar-sail cargo vehicles. Fifty to sixty shuttle payloads would be needed for the mission, of which about twenty would be used to construct a fleet of two-kilometer-square sails. These could tow over 400 tons of equipment and supplies—enough to support an initial Mars landing crew of eight—from a staging area in low-Earth orbit to Mars. The trip to Mars would take almost four years, but the solar-sail vehicles could also serve as a continuous ferry for samples and supplies between Earth and Mars.

Another promising technology for cargo ships is electric propulsion, or "ion drive." This technology uses electric power to transform a propellant into charged particles, which are then accelerated by an electric field and expelled at high velocities. The thrust of the electric-propulsion engine depends on the rate at which the ions are expelled, which in turn depends on the size of the electric power supply. Currently available power supplies provide an engine thrust that is low compared with chemical propulsion. However, an ion-drive engine consumes only one-tenth the fuel of a chemical engine to produce the same propulsive force.

Born in the mid-1950s, the concept of electric propulsion has inspired small-scale research and development work for decades. In 1970, NASA put a satellite with ion thrusters into orbit and test-fired them over a ten-year period. Early electric propulsion systems used nuclear reactors to provide the power, but the trend since

the mid-1960s has been toward using banks of solar panels. Solar-powered electric propulsion (SEPS) may well be the optimal system for unmanned Mars vehicles. Propellants for solar electric propulsion are either metallic conductors such as mercury or ionizable fluids such as argon gas. Argon makes up 1.6 percent of the martian atmosphere and has been tested for SEPS use at NASA's Lewis Research Center in Cincinatti. If a space vehicle could refuel for a return trip with argon derived from Mars' atmosphere, the weight that must be launched from Earth, and hence mission costs, would be reduced.

The solar panels from a SEPS engine could also be used to generate electricity when a spacecraft is parked in Mars orbit. As first proposed by Peter Glaser of Arthur D. Little, Inc., in Cambridge, Mass., this electrical energy could conceivably be converted to laser or microwave radiation and beamed to receiver stations on Mars. Such a process may be better suited to providing power on Mars than on Earth, because the thin atmosphere will not scatter the beams and there is clearly less potential for biological harm.

The disadvantage of solar-sail and electric propulsion systems is that neither has enough thrust for a planetary takeoff. However, a hybrid system could use chemical propulsion to escape gravity and solar sails or electric propulsion for interplanetary flight. Fuel requirements for the hybrid system would be several times lower than for chemical systems alone.

To minimize the crew's exposure to the potentially harmful effects of space flight, the manned spaceship must travel at speeds faster than are possible using solar sails or electric propulsion. Therefore, conventional chemical propulsion such as that used on the space shuttle is the best option in the near future for manned vehicles.

Once the manned spaceship arrives at Mars, fuel could be saved by "aerobraking"—using the upper layers of the planet's atmosphere to slow the vehicle's passage. Aerocapture occurs when the craft sheds enough of its initial velocity to enter an orbit around the planet. The conventional breaking method, in which forward-facing rockets slow the spacecraft, consumes a great deal of fuel. A vehicle using the aerocapture technique could potentially put twice as much payload weight into Mars parking orbit for the same launch cost as could a vehicle using rocket engines alone. A mission using both aerocapture and solar-sail or

"The Moon Is Not the Ultimate Goal"

It's been said that if all the spaceships ever proposed for traveling to Mars were actually built and then laid end to end, the result might reach halfway to the intended destination. That's stretching things a bit, but many proposals have been advanced for traveling to the Red Planet.

Wernher von Braun, who pioneered the development of rockets that eventually propelled astronauts to the moon, made the first detailed analysis of a Mars mission in 1952. His engineering blueprint, published as the *Mars Project*, called for a shuttle-like vehicle that would ferry huge amounts of equipment from Earth to an orbit in space, where it would be assembled into ten spacecraft. The ships, each carrying a crew of seven, would then travel in convoy, and the landing party would spend 400 days on the martian surface.

In the early sixties, when the unswerving focus of the Apollo program seeded boundless excitement for space exploration, the idea of a manned mission to Mars received serious attention. In 1963, the American Astronautical Society sponsored what was called the first planning symposium, which drew 800 scientists and engineers.

The next year von Braun, who was then director of the Marshall Spaceflight Center in Huntsville, Ala., organized a similar conference. "Although the nation is firmly dedicated to achieving a manned lunar landing in this decade, landing on the moon is not the ultimate goal," he declared. "Man will travel beyond the moon to explore the solar system. When, I do not know. But it will take all the disciplines of technology and management to push the frontiers of space into the backyards of the planets."

By the time of the 1969 Apollo moon landing, space engineers had developed a "NASA standard man-to-Mars mission," writes James Oberg, an engineer at the Johnson Space Center in Houston, in *Mission to Mars*. "For many space workers, the moon was only a detour, a temporary distraction from the serious business of getting to Mars."

However, politics intruded. The expensive war in Vietnam aroused the anger of Congress, and President Nixon viewed a costly space program as a potential liability. NASA saw its budget clipped and its horizons foreshortened.

Officially, any plans for a manned mission to Mars retreated to the back of the file drawer. But unofficially, individuals continued to develop plans in private, biding time until the political winds freshened in their direction.

In the spring of 1981, this underground of Mars enthusiasts emerged at a conference organized by Carol Stoker, Christopher McKay, and a number of other students at the University of Colorado. About one hundred people met for three days, drawing up ideas for everything from propulsion systems to martian farms. The participants also identified many of the critical problems and outlined areas for further research.

"Among all these plans are bound to be ideas useful when the time comes again to officially plan a NASA man-to-Mars expedition," writes Oberg. "If not, there is little doubt that their plans have been carefully translated into Russian."

Mars enthusiasts are continuing their efforts today. The Mars Institute, recently started by the Planetary Society, will sponsor courses at various universities for studying a manned Mars mission. And a Second Case for Mars conference will meet in Boulder in July 1984.—*Jeanne McDermott* □

SEPS cargo vehicles would reduce fuel requirements and help offset the development costs of these new propulsion systems, particularly if there is a long-term settlement on Mars.

Over the Long Haul

The trip to Mars will last longer than any manned mission ever launched. Each interplanetary haul will take nine months, and the crew will have to stay a minimum of one year on Mars to take advantage of the optimal alignment of Mars and Earth for traveling. Thus, the shortest trip will last over two and a half years, much of which the crew will spend in the spaceship.

During such a long voyage, the crew must feel comfortable. Unfortunately, the larger the spaceship, the more expensive it is to launch. But Thomas C. Taylor, a consulting engineer from Taylor Associates of Los Angeles, has proposed a low-cost way to build the crew's quarters. While working on the oil pipeline in Point Barrow, Alaska, where packing crates for oil-rig supplies were used as dwellings and clubhouses, Taylor recognized the value of recycling materials. He suggests saving and retrofitting the shuttle's external fuel tank for life-support facilities for a manned ship. This tank is lightweight and extremely roomy; in fact, it is five times larger than *Skylab*, which housed three astronauts for 84 days. Best of all, the tank would already be in space—it now drops off from the shuttle when its fuel is expended and burns up in the atmosphere. But if the tank were boosted into a slightly higher stable orbit, it could be retrofitted for Mars transit at the space station.

Several retrofitted tanks could be joined together to accommodate larger crews. Furthermore, if crews found the deleterious effects of microgravity too severe, several tanks could be connected in a donut-shaped configuration and rotated to produce artificial gravity.

Life Support

Meeting the human requirements of long interplanetary flights is one of the most difficult challenges. Astronauts must have adequate diets and avoid overexposure to toxic substances and radiation. They must adapt to space sickness and the lack of gravity. They must deal with the psychological stress associated with isolation and confinement. And when they land, they must readapt to a high-gravity environment.

Each crew member will need four pounds of water, three pounds of food, and two pounds of oxygen a day. Life-support systems can be "open," so that all materials are provided fresh and used only once, or "closed," so that waste products are processed and recycled. The open system is simple and reliable but its cost climbs as the trip lengthens. The closed system may require heavy, complex, and fail-safe recycling equipment but may weigh less for long missions.

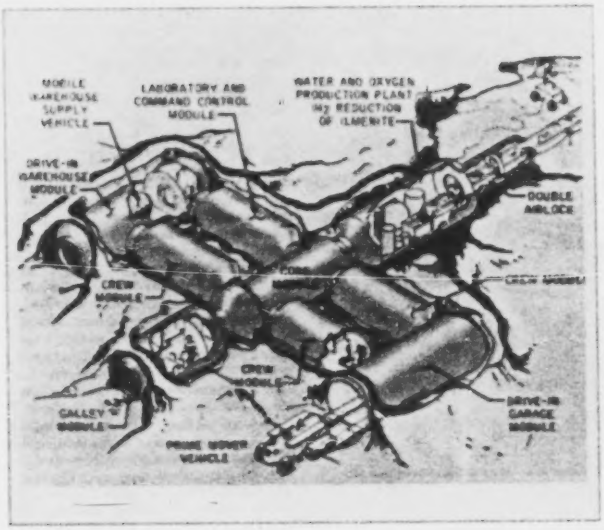
Current technology for closed and semiclosed life-support systems is inadequate for long stays in space, but both are receiving renewed attention because they will be essential for a space station. Partial recycling of food, water, and waste will be easier to achieve than total recycling. Revitalizing the air, which includes removing carbon dioxide, is essential, and can be accomplished with the technology already on the shuttle. The Soviets recycle 50 percent of a spaceship's water simply by recovering exhaled water from cabin humidity. Recovering water from wash water and urine, although difficult, can be done using a complex procedure of distillation and filtration. Recycling solid waste to grow food is the most expensive and difficult process of all and will probably not be cost effective.

Space takes a toll on human health—but just how serious a toll remains to be seen. In microgravity, the heart and other muscles atrophy. Although exercise can help maintain muscle tone, designing a program that adequately uses all the muscles is difficult. The Soviets, who have considerable experience with weightlessness, combat the problem with elastic space suits that force the muscles to work continuously.

Perhaps a more insidious problem is the loss of calcium from weight-bearing bones. Physicians are not certain why this occurs, but they have noticed that patients bedridden for months in a body cast suffer the same loss. A 10 percent loss of bone calcium is considered serious, and astronauts may lose up to half a percent a month. Some drug therapies have been suggested to halt or at least slow this condition, but they remain untested. Fortunately, loss of calcium stops and reverses on return to a high-gravity environment. However, a crew could be highly susceptible to bone fracture for a period after landing on Mars.

Another major health concern is the high amount of radiation astronauts will encounter throughout the flight to Mars. Astronauts will be exposed to at least 40 rems per year of harmful background radiation from the sun and other stars. In addition, solar flares deliver upward of 60 rems of radiation in an average year and several times that amount in a bad year. Federal health standards allow a total ex-

38-036 O - 84 - 62



A permanent Mars base must be near water, fuels, minerals, and building resources, and be situated to allow communication with Earth. The site must also be close to scientifically interesting regions. An early NASA scenario thought a permanent base might look like this (left). Before Mars is settled, its surface should be mapped for water and minerals using NASA's proposed geoscience/ climatology orbiter.

posure of 300 rems over a 20-year career. For protection against short, fierce solar flares, a Mars ship will need a "storm cellar" designed to place as much mass as possible between the crew and the sun. The radiation hazard might favor selecting older astronauts, or at least those past childbearing age.

To maintain astronauts' mental health, Dr. B.J. Bluth, a space psychologist at California State University in Northridge, suggests sending a minimum of seven crew members on any mission. The crew should be composed of an odd number of personnel to prevent deadlocks in command and ensure democratic decision making. It should include both men and women of different professions, backgrounds, and personalities who are taught to withstand the demands and stresses of the mission, and to work together equitably and develop a chain of command and protocol. While the Soviet space program has had considerable success in teaching astronauts how to manage stress, this type of training has been lacking in the U.S. space program.

Settling In

When manned ships first arrive on Mars, the crew's first priority will be to establish a permanent base as self-sufficient as practical. For safety reasons, the pioneering crew should go to Mars with enough food and supplies to last the entire mission, but later crews can rely on locally produced supplies. The martian water supply will have to be tapped immediately. Thomas Meyer of the Boulder Center for Science and Policy has suggested using conventional air compressors to obtain water. At typical nighttime temperatures, martian air is at nearly 100 percent relative humidity. If it is compressed while keeping the temperature constant, water will condense. Meyer and colleagues estimate that extracting each kilogram of water will require up to 400 kilowatt-hours of electricity to drive the compressors. Although supplying that amount of energy may be difficult, the atmospheric supply of water is inexhaustible because water is replenished through evaporation at the poles.

Water could also be extracted by heating martian soil. Dr. Benton Clark of Martin Marietta Co. in Denver estimates that 10 to 100 metric tons of water could be extracted per month, even from dry martian soil, using a 50-kilowatt heat source. Finally, the ice reservoirs at the poles or the permafrost in the lower latitudes could be mined with excavating or blasting equipment.

An air supply will be needed inside dwellings and workplaces. Breathable air must have enough oxygen pressure and an inert buffer gas that inhibits combustion. Carbon dioxide, the primary constituent of martian air, will liquify if the air is compressed and can be processed to obtain oxygen. Nitrogen and argon, the other major constituents of the martian atmosphere, could be used as buffer gasses after the carbon dioxide is removed. Since the buffer gas is not directly consumed, it would not have to be continuously resupplied.

Solar panels could provide power for the base, either from the orbiting SEPS spacecraft or on the ground. A small nuclear fission reactor is also a realistic power option. Although the equipment for both systems must be carried to Mars, neither requires frequent resupply.

Fuels for the return trip could possibly be made on Mars or its moons. An argon-propelled SEPS ship could be refueled using argon from martian air. The chemical propellants burned during takeoff and landing could also be resupplied if enough water is available. Solar or nuclear-generated electricity could be used to split the water into oxygen and hydrogen for the rocket fuel. Hydrogen could also be reacted with carbon dioxide to produce methane, which can be used as fuel.

Martian soil could be the basis for greenhouse agriculture. Although the soil contains sodium and magnesium sulfates as well as sodium chloride, these salts can be diluted with sufficient washing. Adding organic material from human waste will improve the soil's fertility. And the nitrogen in martian air can be reacted with hydrogen to produce an ammonia-based fertilizer.

Standard food crops could be grown in above-ground greenhouses. Penelope Boston, a biologist at the University of Colorado, has shown that plants can grow at low atmospheric pressure. She suggests using plastic tents that maintain an air pressure 10 percent of that on Earth. Greenhouse air could be produced by

manipulating the gas composition of martian air for optimal plant growth. Oxygen, the by-product of plant photosynthesis, could possibly be filtered from the greenhouses for use in human habitats.

Construction and manufacturing materials can also be made from martian soil. With the addition of water, soil can be formed into an adobelike brick for use in building houses. Dr. Benton Clark of Martin Marietta Co. has proposed processes to create a number of other building materials. For example, magnesium is a machinable metal that can be extracted from martian soil. Soil can be converted to glass by heating it to a high temperature. And a wide variety of cements can be easily manufactured using calcium, magnesium, and sulfur compounds.

Living quarters and seed-storage areas are best kept underground to shield people and seeds from radiation damage. Underground habitats also provide natural insulation against the temperature extremes of the martian environment. In addition, they could be easily sealed to enclose a breathable atmosphere.

Because of the low atmospheric pressure and temperature extremes on Mars, humans must wear pressurized and thermally insulated suits above ground. The suits must allow a range of at least 5 kilometers and be flexible enough to perform complex tasks. Life-support requirements would limit a manned rover, needed for exploring and expanding the base, to a range of about 50 kilometers.

The Mars base will ultimately be devoted to science after it is well established. Exploration and research will require remote-controlled vehicles able to travel at least 1,000 kilometers and return samples to the base. Such vehicles would not require the sophisticated artificial intelligence and mechanical design of a self-sufficient robotic rover, as the scientist operating the vehicle could decide how best to avoid an obstacle or which samples to retrieve. Several types of remote-controlled or robotic rover vehicles have already been proposed, including the Mars airplane—a glider designed by Victor Clarke of NASA's Jet Propulsion Laboratory and colleagues for the low atmospheric pressure of Mars. With a 21-meter wingspan, the glider can range up to 10,000 kilometers, carry and land instrument packages, collect samples, and conduct aerial surveys.

What Will It Cost?

Probably the most important factor in the decision to go to Mars is the mission's cost. The high cost of landing on the moon profoundly influenced the public's and politicians' attitude toward space exploration. Legislators and even NASA administrators often assume that new programs will cost much more than Apollo, disregarding the advances that have occurred since the Apollo era.

A manned mission to Mars first appears to be extremely ambitious and therefore prohibitively expensive. However, a detailed study by Humbold Mandell, Jr., a cost analyst at NASA's Johnson Space Center in Houston, indicates that, as mentioned, a single manned mission to Mars could be staged for one-half to one-third the cost of the Apollo program—or just over $20 billion compared with about $60 billion (in 1981 dollars). The total cost of a Mars landing would represent less than 1 percent of the estimated gross national product for 1990, while the total cost of Apollo was 2.8 percent of the average GNP during a single year during that time. Today's military budget annually is over 10 percent of the GNP.

In his estimate, Mandell assumes that the Mars mission would have a short, Apollo-style landing and use the space shuttle and today's space hardware. Costs would be lower than those of the Apollo program because much of the necessary technology already exists, and many development costs could be shared with other programs such as the space station.

A program that established a continued presence on the martian surface would cost more in the long-term. However, while some observers may suggest limiting the exploration of Mars to one or a few Apollo-style missions, the benefits of these missions diminish with their scope. Small-scale missions would fail to adequately study or develop the planet's economic and strategic potential. Considering the unique economic, social, and political implications of a martian settlement, cost should not be a deterrent.

Public interest in and support for exploring space are unquestionably reawakening. However, the motives behind this resurgence are very different from the international competition that first sent us to the moon. A program to settle Mars would provide the focus to meet the new challenge. □

Mariner Mark II and the Exploration of the Solar System

Marcia Neugebauer

Summary. Mariner Mark II is a concept for the next generation of deep-space missions. The project would provide limited, focused sets of Voyager- and Galileo-quality planetary observations at a fraction of the cost of the Voyager and Galileo projects. This article discusses Mariner Mark II's cost goals, scientific objectives, and mission requirements. Strategies for limiting costs include the use of a reconfigurable spacecraft, a multimission ground-support system, and selected new technologies.

As planetary spacecraft technology evolved from the relatively simple Mariner flybys of Venus and Mars to the planned Galileo mission to Jupiter, the emphasis has always been on improved performance. Each mission has returned greater amounts of more sophisticated data than its predecessors. Today, because of severe economic constraints, the outlook is different. The Solar System Exploration Committee (SSEC) of the National Aeronautics and Space Administration (NASA) has been developing a strategy for future planetary research based on a lower cost per mission rather than higher performance.

The SSEC is considering both near-Earth and deep-space missions. Many of the near-Earth missions (to the moon, Venus, Mars, and Earth-approaching asteroids) may be accomplished at relatively low cost with the present generation of Earth-orbiting spacecraft. Several aerospace companies are analyzing methods for adapting spacecraft such as Tiros, Atmospheric Explorer, Fltsatcom (fleet satellite communications), and GOES (geostationary orbital earth satellites) to study Martian geochemistry, climate, and atmosphere, to map the geochemical properties of the moon, or to explore a near-Earth asteroid.

Deep-space missions to comets, main-belt asteroids, and the outer planets require specially designed power, telecommunications, and thermal control systems that operate over a large range of distances from Earth. Under the direction of NASA and SSEC, the Jet Propulsion Laboratory is studying the development of a workhorse called Mariner Mark II for the next generation of deep-space planetary missions. Mariner Mark II is being designed to perform limited sets of Voyager- or Galileo-quality measurements in deep space or to deliver Galileo-type atmospheric probes to the outer planets at a fraction of the cost per mission of the Voyager and Galileo projects.

Tens of thousands of striking pictures of the Jupiter and Saturn systems were sent back by Voyager (*1*). These pictures were obtained by a black and white television camera with a resolution of 800 by 800 picture elements (allowing finer detail than possible with the 520 lines of an ordinary television). Color photography and spectral information were obtained by sequential use of a set of different filters. For Galileo, the Vidicon television tube used on Voyager will be replaced by solid-state detectors called charge-coupled devices (CCD's) to achieve wider spectral response, greater photometric accuracy, and increased sensitivity. The term Voyager- or Galileo-quality also implies the following: (i) the capability to map certain physical properties and the chemical composition of individual features on the surfaces of solid bodies; (ii) the capability to determine the structure and dynamics of planetary atmospheres together with the abundances of many specific atoms and molecules by remote sensing at ultraviolet, visible, and infrared wavelengths; (iii) the capability to send an instrumented probe into a planetary atmosphere to sense the frequency and intensity of lightning bursts and to directly sample pressure and temperature structure, composition (both elemental and isotopic), and the size and shape of aerosols; (iv) the capability to measure the composition and distribution of energetic charged particles and low-energy plasmas in planetary ionospheres and magnetospheres, together with the magnetic field and plasma waves that interact with the charged particles; and (v) the capability to determine the distribution and some of the physical and chemical properties of dust grains by observing the details of how they absorb and reflect sunlight and by direct measurements of a few individual grains.

Mariner Mark II starts with these existing capabilities and uses new technology principally to reduce mission costs rather than to improve spacecraft performance. The spacecraft would be reconfigurable at low cost to meet the different requirements of different missions, while a multimission ground system would be able to support any of the spacecraft without reconfiguration.

The cost history of U.S. planetary and interplanetary projects is shown in Fig. 1 in terms of both dollars spent and an equivalent 1982 cost that accounts for inflation. Twin spacecraft, such as Voyagers 1 and 2, are counted as a single project. A much lower than average cost characterizes missions that were based on the designs of earlier missions. These

Marcia Neugebauer is a senior research scientist and acting manager of the Mariner Mark II Development Flight Project at the Jet Propulsion Laboratory, California Institute of Technology, Pasadena 91109.

include Mariners 1 and 2, derived from earlier Ranger spacecraft; Mariner 5, derived from Mariners 3 and 4; and Mariners 8, 9, and 10, derived from Mariners 6 and 7. The goal of the Mariner Mark II project is to develop the capability for a series of planetary missions in the 1990's with a 1982-equivalent cost between $150 million and $300 million per mission. For a sequence of four or five missions in 10 years the average expenditure per year is planned to be limited to approximately $100 million. The data in Fig. 1 suggest that these goals are probably attainable if a high level of inheritance can be achieved across missions.

Ironically, one reality that brings the Mariner Mark II goals within reach is the present time gap in funding planetary exploration. The Galileo project, which was approved and started in 1977, is the only planetary mission under development in the United States. The gap between the start of Galileo and the start of the next deep-space project is being used to examine the requirements of this next generation and to determine the most cost-effective way of meeting them.

The study of comets is one of the highest priorities of future planetary research (*2*). Comets are the only obtainable source of the primitive material from which the solar system evolved. They are believed to contain a record of the physical and chemical conditions of the interstellar medium and the primordial solar nebula. Furthermore, comets may have contributed appreciable amounts of volatile material to the present atmospheres of the terrestrial planets (*3*); it has also been suggested that cometary material was important to the evolution of life on Earth (*4*).

The 1986 European, Soviet, and Japanese flybys of Halley's comet will address many important questions about the composition of the gas and dust that form the cometary halo and tails visible from Earth. The missions are expected to verify Whipple's (*5*) hypothesis that cometary nuclei are small (diameter, 0.1 to 100 kilometers) "dirty snowballs" that vaporize and become very active when they come close to the sun.

A thorough investigation of a comet requires a much longer period of observation than that provided by a flyby mission. A rendezvous mission is required so that the comet can be watched for a period of months as it approaches and retreats from the sun. With very small propulsion maneuvers, a spacecraft in rendezvous with a comet can move around the nucleus and view it from different distances and directions. The physical and chemical nature of the nucleus can be determined with Galileo-quality imaging and infrared mapping systems as well as with x-ray or gamma-ray spectrometers. Direct measurements can also be made of the gas and dust in the comet's atmosphere.

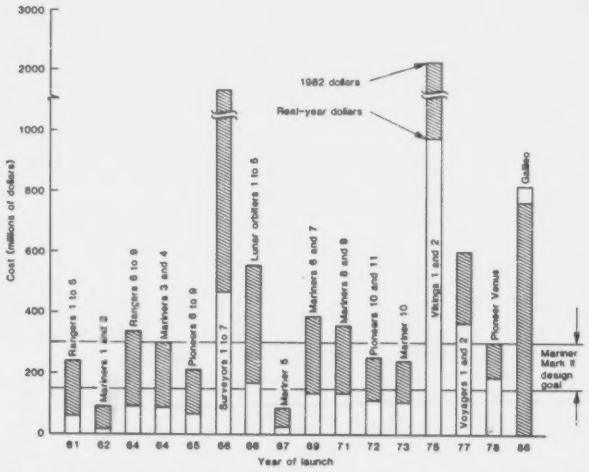

Fig. 1. Deep-space mission costs. The figures reflect current NASA bookkeeping practice in that they include all costs of building and operating the spacecraft and analyzing the returned data, but not the cost of either the launch vehicle or the operation of the deep-space data acquisition facilities. Data for Pioneers 10 and 11, Pioneer Venus, and Voyager are through the end of fiscal year 1981.

The choice of targets for a comet rendezvous is limited by available and planned launch vehicles to short-period comets in low-inclination orbits. Comets Honda-Mrkos-Pajdusakova and Tempel 2 are the two best candidates for the 1990's.

While observations with a rendezvous spacecraft can enormously increase our knowledge of comets, the ultimate step would be to collect and return a portion of a comet's nucleus for detailed analyses in sophisticated ground-based laboratories. The propulsion capability required to carry out such an ambitious task is not available; it is possible, however, to sweep up cometary gas and dust with a spacecraft that passes through a comet's atmosphere at high velocity and to return that sample to Earth for analysis. The spacecraft would necessarily move through the comet at such high speed that information about the physical and chemical states of the dust and gas would be lost because of vaporization and plasmatization caused by the impact. But elemental and isotopic analyses of the collision debris would provide new information on the generic relation of the comet to other solar system bodies and to interstellar matter. A high degree of synergism can be gained by studying the same comet with simultaneous rendezvous and sample-return missions.

Like comets, asteroids are relevant to a wide variety of questions about the origin and evolution of the solar system. Since asteroids are relatively small bodies, it is thought that radiogenic heating and other endogenic processes have had much less effect on them than on larger bodies such as the Earth and moon. An asteroid's structure and morphology and some features of its mineralogy and elemental composition should indicate its environment and state during and shortly after its creation. Earth-based observations indicate that there are many different types of asteroids. For spacecraft missions there are two sets of objects to be considered: main-belt asteroids between the orbits of Mars and Jupiter and Earth-approaching asteroids on temporary, unstable orbits with typical lifetimes of a few tens of millions of years. The source of Earth-approaching asteroids is not known; some or all of them may be exhausted comets. There is also an apparent systematic variation of composition with position in the asteroid

belt, which is probably a relic of radial gradients in the condensing solar nebula. The diversity of asteroids requires that more than one type be studied at close range.

The Mariner Mark II study addresses the possibility of performing a rendezvous with one or possibly two main-belt asteroids and flying by several others, all with a single spacecraft. Main-belt asteroid rendezvous missions could be achieved with Galileo-era launch vehicles by designing a trajectory that takes the spacecraft close enough to Mars to obtain a gravitational boost in orbital energy from that planet. Additional energy could be gained by proper timing of a rocket firing during the Mars encounter. Such a maneuver would allow the spacecraft to obtain an asteroid-like orbit about the sun. Once the spacecraft reached the asteroid belt there would be a very large number of target bodies to choose from.

Future planetary exploration will also focus on the outer planets. Again, the emphasis will be on learning more about the origin and evolution of the solar system. Systematic differences between Jupiter, Saturn, Uranus, and Neptune reflect radial variations in the physical and chemical properties of the primordial solar nebula. The outer planets have a wide variety of satellite and ring systems; understanding the dynamics of these systems is a prerequisite to understanding the agglomeration and accretion of the planets and their satellites. Other than the Earth, Saturn's moon Titan is the only solar system body with a nitrogen-rich atmosphere. Titan has been likened to the Earth early in its development. Large amounts of methane are also present, which raises the possibility of organic chemical reactions, possibly similar to those on the prebiotic Earth. It is possible that methane is near saturation in Titan's lower atmosphere and that liquid methane is present on the surface.

The Pioneer and Voyager missions provided an initial reconnaissance of Saturn and its rings and satellites, and Voyager is expected to do the same at Uranus in 1986. To achieve the next level of understanding, Mariner Mark II could deliver entry probes or provide a Saturn orbiter. Because Titan's atmosphere is opaque at visible wavelengths, Voyager could learn only a little about the composition and structure of its atmosphere and nothing about the physical nature of its surface. New data could be obtained by sending an instrumented probe into Titan's atmosphere and by observing Titan at infrared and radio wavelengths. Radar and infrared mapping could be carried out from the spacecraft used to deliver the atmospheric probe and to relay its data to Earth. More complete mapping could be conducted from a spacecraft in orbit around Saturn.

A Saturn orbiter would, of course, have other objectives in addition to studying Titan, and a variety of different Saturn orbits can be obtained by repeated close flybys of Titan. The 3-year scenario shown in Fig. 2 features 22 encounters with Titan plus close (< 2500 km) encounters of the satellites Dione, Rhea, Hyperion, and Iapetus. The key element provided by a Saturn orbiter is the ability to study satellite surfaces and Saturn's atmosphere as well as ring and magnetospheric phenomena over an extended period of time and at a variety of geometries and conditions.

As with Titan, new data about the atmospheres of each of the outer planets can be obtained with entry probes. Instruments like those carried on the Galileo Jupiter probe would be able to measure the molecular and isotopic compositions of the atmospheres of Saturn, Uranus, and Neptune as functions of depth down to pressure levels of 10 to 20 bars.

The Mariner Mark II is principally designed to study minor bodies and the outer solar system. But its capabilities could be applied to study the terrestrial planets as well. The option that has been studied in greatest detail is a Mars orbiter suited for geochemical and climatic studies. The reason for studying Mars is not so much to increase our knowledge of how the solar system evolved but rather to learn more about how it is evolving and, in particular, to understand what may be in store for the Earth. An understanding of past and present processes on Mars requires mapping of the chemical and mineralogical characteristics of the surface and determining the sources, sinks, abundances, and circulations of volatiles and dust in the atmosphere.

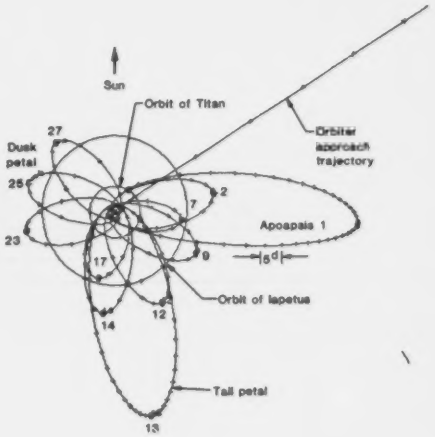

Fig. 2. Example of one possible 3-year tour of the Saturn system (6). For clarity, only ten of the 26 orbital loops have been drawn.

Mission Characteristics and Requirements

The space shuttle would be used as a launching platform for all the Mariner Mark II missions. The boost out of low-Earth orbit would be provided by the Air Force two-stage Inertial Upper Stage (IUS) or a higher energy Centaur rocket using liquid hydrogen and oxygen as fuels (Table 1). Funds for the development of a shuttle-compatible Centaur were approved in July. Some proposed missions require still another stage of propulsion, which could be provided by a Star-48 solid rocket motor after the IUS or Centaur has burned out and been jettisoned.

Most of the candidate missions have substantial requirements for postlaunch propulsion for orbit insertion, for matching the velocity vector of a rendezvous target, or for interplanetary maneuvers required to reach the target. Many of the candidate missions are also of long duration, ranging up to 11 years. This fact has a significant impact on the reliability

required of the spacecraft and on the level of redundancy in the design.

Many of the missions will require precise navigation. The Titan mission must rely on optical navigation for acceptably accurate delivery of its atmospheric probe. The ephemerides of the comet and asteroid targets are even less well known because of the relative scarcity of observations. Furthermore, as gas escapes from the warmer side of a comet, conservation of momentum results in an acceleration of the comet body in the opposite direction. The comet's orbit can be substantially altered by such jet action. Optical navigation requires imaging of the comet or asteroid against a background of stars of magnitude 9 or 10. This requirement can be easily met with the Galileo CCD camera sensor on a three-axis–stabilized platform.

Voyager- or Galileo-quality imaging will also be of highest scientific priority for the comet and asteroid rendezvous and the Saturn orbiter missions. Remote-sensing instruments also benefit greatly if the spacecraft is able to keep them trained on the target. Measurements that require long integration times are made possible through the use of a platform with active pointing control. Over 80 percent of the surface of Titan can be mapped with a radar antenna mounted on a movable scan platform such that one hemisphere is viewed on approach and the other as the spacecraft leaves Titan. Thus, navigation and remote sensing both call for a stabilized rather than a spinning spacecraft.

The imaging systems, multispectral mapping instruments, and radar for the Titan mission will all produce large amounts of data. Model profiles suggest that, even with the data compression techniques now coming into use, telecommunication rates will be on the order of 10,000 to 30,000 bits per second. The data links must be maintained over distances as great as 10.5 astronomical units (AU) for Saturn. The distances to Uranus and Neptune are even greater, but the smaller amount of data acquired by flyby and probe missions can be stored and then transmitted at a lower rate.

Other requirements of the Mariner Mark II spacecraft include the following: (i) it must operate at distances from the sun ranging from 1 to 30 AU, if a Neptune mission is included in the set; (ii) it must be capable of carrying and releasing an atmospheric probe or a capsule to return material to Earth; (iii) for missions with high-resolution imaging, it must have a pointing accuracy of about 2 milliradians; and (iv) it must support and be compatible with the scientific instruments to be flown.

The basic requirements of the Mariner Mark II spacecraft are summarized in Table 2. Some of these requirements would have to be extended, at additional cost, to carry out certain missions. These extensions include an on-board propulsion capability between 3 and 4 km/sec for some multiple main-belt asteroid tours, longer durations and larger distances for the Uranus and Neptune missions, and a closer approach (0.34 AU) to the sun if Encke were chosen as the target for a comet rendezvous mission.

Implementation

How is it possible to meet the requirements listed in Table 2 and the Mariner Mark II cost goals at the same time? The strategy, which is based on the assumption that Mariner Mark II will be used for a series of four or five missions over a 10-year period, has four components: (i) objectives and operations must be kept as simple as possible; (ii) the system must be easily reconfigured from one mission to the next; (iii) requirements must be set to provide more conservative design margins than in the past; and (iv) new technology should be used to reduce costs rather than to achieve performance beyond the minimum mission needs.

Simplicity. One way to keep the missions simple is to restrict the scientific objectives of each mission. Figure 1 shows that Viking and Galileo are two of the more expensive recent projects. Both missions have diverse rather than

Table 1. Summary of candidate Mariner Mark II missions.

Mission	Launch opportunities	Launch mode*	Mission duration (years)	Time spent at target	Post-launch ΔV (km/sec)
Comet rendezvous	1989, 1990,† 1991, 1992, 1994, 1995, 1996	Centaur	5.5	6 months	2.2 to 2.9
Comet sample return	1989, 1990, 1992, 1994, 1999	IUS	2 to 3	1 day	0.2 to 1
Main-belt asteroid flybys and rendezvous	Every 26 months	IUS, S48, and MGA or Centaur and MGA	2 to 7	6 months	3 to 4
Saturn orbiter	Every year (1998†)	Centaur and JGA	7 to 11	≤ 3 years	2.0 to 2.3
Titan or Saturn flyby and probe	Every year	Centaur and S48	3.5	1 day	0.2
Uranus flyby and probe	1992, 1994†	Centaur, S48, and JGA	5.5 to 8‡	1 day	0.2
Neptune flyby and probe	1992, 1994†	Centaur, S48, and JGA	8 to 10‡	1 day	0.2
Mars orbiter	Every 26 months	IUS	2.8 to 3.2	2.2 years	2.2 to 2.7

*The spacecraft would all be launched from the space shuttle by either a two-stage IUS propulsion system or by the higher performance Centaur. A notation of S48 indicates that an additional stage of propulsion equivalent to a Star-48 solid rocket motor is also required. Missions in which momentum is gained by flying by Mars or Jupiter are indicated by MGA or JGA, respectively. †Best opportunity. ‡The longer flight times would be required to avoid a close flyby of Jupiter, which requires special radiation hardening of spacecraft.

focused objectives. The Viking project had two orbiters for global mapping plus two landers that probed the atmosphere and then made detailed observations of the two landing sites. The Galileo project includes an atmospheric probe and an orbiter. The orbiter, in turn, has a three-axis–stabilized section to optimize remote sensing of Jupiter and its moons and a spinning section to optimize magnetospheric measurements. For Mariner Mark II, a Saturn probe, Titan probe, and Saturn orbiter would be three separate, focused missions. Furthermore, the Saturn orbiter would not have a spinning section. Adequate magnetospheric particle measurements could still be made with sets of wide-angle sensors. The disadvantage of a fixed orientation for magnetospheric measurements is generally outweighed by its advantage for remote sensing.

The ground-support system must also be as simple and as inexpensive as possible. Two keys to simplification of the ground system are automation and autonomy of the spacecraft—which, of course, increase the spacecraft's cost. The Mariner Mark II missions are generally of such long duration that the net payoff for on-board automation would be high. The spacecraft must be able to care for itself for many days without commands from the ground. During the long cruise toward the target, a radio signal would continuously indicate the state of health of the spacecraft. This signal would be monitored once or twice a week and an alarm system could be automatically activated if anything were amiss.

Once at the target, the sequencing of spacecraft operations must be as simple as possible, with a minimum number of modes or states of activity. With its large number of satellite encounters, the Saturn orbiter tour (Fig. 2) would be especially vulnerable to an escalation of costs associated with spacecraft and instrument sequencing. The inclusion of an automatic target tracker and "smart," self-adjusting instruments might be cost-effective for such a mission.

Each instrument must also operate as independently as possible. Power and data handling margins would be sufficiently large to allow an instrument to change its mode of operation, either automatically or by ground command, without prior coordination, scheduling, and simulation of the effect of the change on the spacecraft and the other instruments and without verification of proper receipt of commands.

Reconfigurability. A basic requirement of the Mariner Mark II concept is that the spacecraft be reconfigurable at low cost from one mission to the next. A high degree of inheritance from mission to mission must be planned from the start. A modular spacecraft configuration is being developed to satisfy this requirement over the range of missions listed in Table 1 (Fig. 3). The baseline attitude control mode is a three-axis, celestially fixed attitude with the Earth and a bright star as references. A central module houses all of the spacecraft electronics and electromechanical and electrochemical assemblies that do not require external mounting.

Table 2. Mariner Mark II spacecraft requirements.

Requirement	Possible extension
Shuttle IUS or Centaur launch	
Postlaunch propulsion, ≤ 3 km/sec	4 km/sec
Mission duration, ≤ 8 years	11 years
Communication distance, ≤ 11 AU	30 AU
Solar distance, 1 to 10 AU	0.34 to 30 AU
Optical navigation	
Attitude control, three-axis–stabilized with 2-mrad pointing accuracy	
Data rate, 10 to 30 kilobits per second	
On-board data storage	
Probe delivery or capsule capacity	
Support of and compatibility with instruments selected for flight	

Several different modules are attached to the central module. The interfaces between each of the external modules and the central module will be as mechanically, electrically, thermally, and logically standardized as possible across the mission set. The design of these interfaces thus requires careful consideration of each of the missions as well as of the possible introduction of new technology.

The radio-frequency module includes a fixed high-gain antenna together with its antenna feed and receiver. A study is in progress to determine whether high-gain antennas of different sizes should be carried on different missions or whether it is possible to meet the requirements of all the missions with a single antenna design. One or more low-gain antennas may also be included in the radio-frequency module for use during emergencies if the spacecraft cannot find the Earth.

The propulsion module provides the impulse for trajectory changes and the reaction control for maintaining the proper orientation of the spacecraft. Figure 3 shows the number of tanks necessary to provide trajectory changes of ~ 1 km/sec.

The power module accommodates a radioisotope thermoelectric generator (RTG) or a solar panel. The RTG is the power source of choice for the outer planet missions. Because an RTG is a source of radioactivity, it must be well shielded and located far away from the scientific instruments to minimize interference with their measurements. An RTG cannot be used at all on missions, such as an orbiter of Mars, in which gamma-ray spectrometers are carried for measuring the composition of the target body by analysis of the low flux of gamma rays that it emits naturally. For such missions the power source would therefore be a solar panel. Space must be set aside in the central module for the batteries required when the panels cannot be in sunlight. The power conditioning and handling equipment in the central module would be the same for all missions, independent of the nature of the power source.

The scientific instruments and attitude control sensors are located on the outside of the central module, on one or more fixed booms, or on an articulated platform. The booms are for instruments that must be isolated from interference associated with the main spacecraft. The articulated platform can rotate about either of two axes to allow the instruments on it to be pointed in almost any direction.

The final module would be a probe for a Titan or outer planet mission or the Earth-return capsule for the mission to return a comet sample. The large propellant tanks needed for interplanetary maneuvers would be jettisoned before the probe is released.

Figure 4 illustrates how the spacecraft could be reconfigured from one mission to the next. Figure 4C shows the probe-carrying configuration of Fig. 3. The configuration shown in Fig. 4A could be used for a Saturn orbiter. This mission requires additional propellant tanks, which fit in where the probe was located in Fig. 4C. Figure 4B shows a Mars orbiter configuration, similar to the Saturn orbiter except that a solar panel would replace the RTG power source, whose radiation would interfere with gamma-ray spectrometer observations. The antenna might also be smaller for a Mars mission than for a Saturn mission. The comet and asteroid rendezvous spacecraft would look like that shown in either Fig. 4A or Fig. 4B, depending on

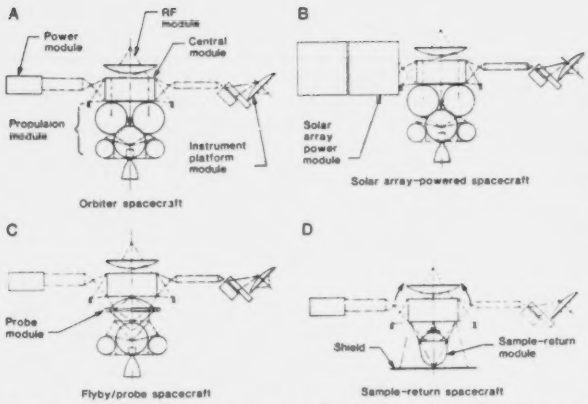

Fig. 4. Reconfiguration of the Mariner Mark II spacecraft from mission to mission. The arrows in (D) indicate two appendages that are to be folded away behind the dust shield during the comet encounter; *RF*, radio frequency.

whether a gamma-ray spectrometer is part of the payload and on how far from the sun the spacecraft must operate. (The latter, in turn, depends on which comet or asteroid is chosen as the target.)

The comet-sampling spacecraft (Fig. 4D) must fly through the cometary dust cloud at high speed. The spacecraft is protected from the dust by a shield and a sample collector. During the flyby the power module and scan platform must be folded back and hidden behind the shield. The shield must be pointed in the direction of the relative velocity vector. If it is necessary to maintain the telemetry link during the flyby, the high-gain antenna would have to be tipped toward Earth.

The requirement for high levels of inheritance and reconfigurability applies to more than just the major spacecraft appendages; it also applies to spacecraft subsystems and the scientific instruments. All missions with high-resolution imaging would use the same Galileo-derived camera design. The other instruments would be treated like "black boxes" as much as possible, with the smallest possible differences in the interfaces for the different instruments. This is made feasible and cost-effective, in part, by the increased use of microprocessors in individual instruments. All but one of the nine Galileo instruments contains a microprocessor. If each Mariner Mark II instrument temporarily stored its own data and formatted it into telemetry packets, the spacecraft data system would not have to be changed in response to changes in the instruments from one mission to the next. Each source-generated data packet contains a standard header identifying its source and length. The spacecraft data system then becomes simply a transportation and storage service. The ground-support system would be based on multimission standards and protocols to such an extent that changes in the science payload or in spacecraft subsystems would be transparent to the machines and people transporting the data. The ground system could support several missions simultaneously.

The modular approach reduces the impact of those changes that must be made. Costs for redesigning, retesting, and flight qualification are minimized. Modularity allows the introduction of new technology into the system piecemeal, as it is proved and qualified. A high level of inheritance enables block buys of items used in several missions. It also simplifies or eliminates the response of the ground system to changes in the spacecraft.

Design margins. To achieve reconfigurability and low cost, adequate design margins are crucial. Design margins provide increments of capability without affecting the overall system design. Adequate margins also lower costs by simplifying designs, manufacturing processes, operations, and sequencing; reducing the amount of performance analysis; and reducing the risk of cost increases associated with design changes.

With respect to Mariner Mark II, large margins have been applied in estimating the performance of its unproved launch vehicles. The analysis that generated the flight times given in Table 1 was based on the pessimistic assumption that the performance of the IUS and the Centaur will be only 80 percent of that expected.

With reasonable mass margins taken into account, the estimated mass of the basic Mariner Mark II spacecraft is about 600 kilograms, exclusive of the propulsion tanks, fuel, and any probes that may be carried. This total includes 97 kilograms for scientific instruments. The estimated mass of a spacecraft inevitably increases during the progression from preliminary design to actual construction. Mass reduction programs required by inadequate initial mass margins have been very expensive. But more important than leaving a margin to cover uncertainties is the ability to "waste" mass to make interfaces simpler and to reduce cost in other ways. The propulsion module is an example of how large mass margins could reduce the cost of the Mariner Mark II missions. If mass had to be minimized, the propellant tanks for each mission would be as small as possible. It would be less expensive, however, to design, build, and test only one or two sizes of tanks and to fill them only partially for missions that require smaller changes in trajectory.

Design margins can also help to reduce the cost of managing power, data storage, computing, and thermal control. For example, the ability to have all instruments and subsystems operate at their peak power levels simultaneously can eliminate a great deal of sequencing activity. Adequate data storage and computing capacities also reduce the amount of detailed planning, sequencing, and memory management.

New technology. Mariner Mark II will make full use of the current gap in planetary missions to take advantage of technical developments. New technology and advanced developments will be used to reduce costs, avoid problems of parts obsolescence, and achieve acceptable performance. The goal is to demonstrate technological readiness through engineering model demonstrations before the start of the project. Several new technologies studied thus far show promise for providing lower recurring costs and a net savings to the project. Examples include the following:

1) An all X-band telemetry system. The Voyager spacecraft receives commands from the ground at the S-band frequency of 2110 megahertz and transmits data in both the S band (~ 2300 MHz) and the X band (~ 8400 MHz). X-band data links are preferred because

directive antenna gain varies directly with frequency squared while noise caused by charged particles along the ray path is an inverse function of frequency squared. The Mariner Mark II two-way X-band system would not only have better performance than the Voyager system, but weight and cost would be reduced because it is simpler and requires less equipment to accommodate one frequency range than two.

2) Fiber-optic rate sensors (FORS) for use as an inertial reference system. A FORS-based inertial reference system has no moving parts and an inherently low drift rate. It might offer distinct cost advantages over the traditional gyroscopes once the integrated optic circuit can be mass-produced. It is expected that, beginning in the late 1980's, industry will invest heavily in the development of fiber-optic components and integrated optic circuits.

3) A multipurpose celestial sensor based on a CCD under microprocessor control. This sensor can image several stars simultaneously to provide a celestial reference for the spacecraft or can be used to track target bodies if mounted on the science instrument scan platform. Closed-loop pointing of this platform might be of particular advantage when the ephemeris of a target body is not well known and might lower costs by reducing sequence planning and platform pointing calibrations.

4) Very large scale integrated (VLSI) circuits. VLSI circuits may be used in command and data handling (CDH) and attitude control subsystems, in interface units between the CDH subsystem and the science instruments, and in other spacecraft subsystems. In one design approach for the CDH subsystem, self-checking computer modules incorporate VLSI and LSI components. VLSI circuits hold promise for reducing the cost, weight, power, and volume of electronic assemblies.

5) Image compression. This is another area where VLSI components could be employed. Newly developed data compression techniques and low error rates allow the number of data bits required to transmit a picture to be reduced by a factor of 1.3 to 4 (depending on the activity of the picture) without any loss of information. There are applications in which much larger compression ratios could be used to trade picture quality for a greater number of pictures. A recent study indicates that optical navigation data can be compressed by a factor as high as 100 without significant degradation of the needed information. Data compression techniques can have a significant impact on downlink telemetry rate, antenna size, transmitter power, and data storage capacity, and therefore on cost.

6) Electronic and optical disk data distribution. If cost-effective, the ground system for Mariner Mark II would allow investigators to have access to their data at remote terminals. This would obviate the need to generate and transport large quantities of hard-copy pictures and magnetic tapes to the data users. There will probably also be significant cost advantages in the use of digital optical disks, which can store an extremely large amount of data and can be reproduced at low cost.

Conclusion

The SSEC is outlining the scientific priorities for planetary exploration in the rest of this century. The Mariner Mark II is being developed to meet the requirements of the deep-space missions on the SSEC's list. The proposed spacecraft could be reconfigured at low cost from mission to mission and be supported by a simplified, multimission ground system. I believe that Mariner Mark II can meet its cost goal of $150 million to $300 million per mission. Discipline will be required to keep the objectives of each mission focused, to limit the complexity and performance of the spacecraft and ground system to the minimum levels required to meet the objectives, and to avoid the use of new technology before its flight readiness has been demonstrated.

After two decades of planetary exploration, we now have the knowledge and experience to select a set of deep-space missions of outstanding scientific value and to implement them at low cost.

A Prelude to Interstellar Flight

By LEONARD D. JAFFE and HARRY N. NORTON
Jet Propulsion Laboratory, CalTech

Before we can think about flying to a star, we must learn how to fly beyond our planets; a star mission is still a dream, but an interstellar precursor mission could soon be a reality

Mankind's reach for the stars acquired a semblance of reality in the increasing achievements in space exploration during the past two decades. Since we are now in the process of exploring the outer planets of our solar system, it would seem appropriate to consider the scientific promise as well as the engineering problems of missions to the stars and, hopefully, their planets.

A brief calculation brings out the primary problem. It would take over 10,000 years to reach the nearest star, Proxima Centauri, at a distance of 4.3 light years (about 4×10^{13} km), if a spacecraft could be given a hyperbolic velocity for solar-system escape of 10^2 km/s (3×10^6 km/yr). Establishing such a spacecraft lifetime, or a much greater velocity, by the year 2000 does not seem possible. The star mission has to be shelved for the time being. But later in the 21st Century, as propulsion improves, it may be possible to make this flight in much shorter time; then it may become feasible.

What could be done in the meantime? In a symposium on "Missions Beyond the Solar System," organized by Louis D. Friedman and held at the Jet Propulsion Laboratory (JPL) in August 1976, the idea of a precursor mission out beyond the planets, but not nearly so far as another star, was suggested as a means of bringing out and solving engineering problems inherent in a star mission. At the same time it was recognized that such a precursor mission could also have significant scientific objectives. A small team was then organized to study the scientific benefits and technology requirements of an interstellar precursor mission.

Space science would, in fact, benefit significantly from such a mission. Characteristics of the heliopause (where solar wind terminates against incoming interstellar medium) and the interstellar medium could be determined by in situ measurements. Stellar and galactic distances could be determined with far greater accuracy through parallax measurements of nearby Cepheid variables using an Earth-to-spacecraft baseline. Cosmic rays having energy levels too low to penetrate the heliosphere could be detected and characterized. The solar system as a

whole, such as its total mass and its internal (interplanetary) gas distribution, could be scoped from a vantage point external to the system. A secondary science objective could be a close-up determination of the characteristics of Pluto and its rings and satellites, if any.[2]

It was decided to concentrate on a precursor mission to a distance of 400 to 1000 AU. (Pluto, our outermost planet, will be about 30 AU from the Sun in the year 2000; Proxima Centauri is 270,000 AU away.) As the concept developed, the duration of the mission was planned as 20 years to reach a distance of around 400 AU. The mission could then be extended to about 50 years to reach a distance of more than 1000 AU.[1]

Engineering of this precursor mission would raise formidable challenges. Major advances in technology, particularly in propulsion and telecommunications and in overall reliability, would have to be attempted and then proven.

Trajectory and Propulsion Choice: Trajectory and propulsion-system selection are the prime design drivers of the precursor mission outward to 400-1000 AU, directed toward the incoming interstellar gas and including a Pluto flyby if possible. The Shuttle or, better, a Shuttle derivative able to deliver more payload was assumed as launch vehicle. Low thrust as well as Jupiter or Venus-Earth gravity-assist trajectories and combinations of these were considered. Low-thrust options examined included solar sailing,[3] laser sailing (with an Earth-orbital laser source illuminating the sails),[4] and solar-electric, laser-electric,[5] and nuclear (fission or fusion) -electric propulsion with ion or magnetoplasmadynamic drive. Some consideration was even given to the use of antimatter production as source of propulsive energy. Dual systems, such as solar-electric propulsion for earlier mission phases and nuclear-electric propulsion for later mission phases, were also studied.

The mission selected demands a heliocentric excess velocity (v_∞) well over 50 km/s. Maximum performance would be provided by an antimatter energy source.[6-9] This may eventually be feasible, but not for a launch in the year 2000. The options able to produce the required v_∞ by then will be solar or laser sailing and nuclear-electric propulsion.

The sail technique—propulsion derived from photon pressure acting upon very large, very-thin-film "sails" attached to a spacecraft—would require formidable technology developments.[10] For a year-2000 launch it may be possible to attain a sail surface with a mass-to-area ratio of 0.3 g/m^2 by making the necessary development effort. Such a sail could be a surface-treated aluminum film about 100 nm thick. It would probably have to be fabricated in orbit. The perihelion distance of the trajectory would have to be at least 0.25 AU to avoid overheating the sail. But it might yield a v_∞ of about 120 km/s.

Reducing the perihelion distance to 0.1 AU would increase the solar photon force, but also the sail temperature. Assuming a reflectivity of 0.9 and a total emissivity (sum for two sides) of 1.0, the sail temperature would reach 400 C. This would call for the use of high-temperature materials. An additional problem is posed by the emissivity itself. It may never be possible to attain 1.0 with a film mass of less than 1 g/m^2, because of the emitted-wavelength/thickness ratio. The emissivity of an 0.3 g/m^2 film would be 0.5 or less; this would increase the sail temperature to 600 C or more. Carbon films could stand such a high temperature, but it would be difficult to give them a highly reflective surface and their mass could most likely not be less than 1 g/m^2 (according to W. Carroll of JPL). Such a sail and trajectory could provide a v_∞ of less than 110 km/s, somewhat poorer performance than for the 0.25-AU perihelion distance case using lower-temperature materials.

In laser sailing the photons acting upon the sail come from a laser instead of from the Sun. The hypothetical case studied assumes an incident photon flux equivalent to 1700 "suns" at 1 AU.[11] A high sail reflectivity, perhaps 0.99, could be attained because the laser energy is monochromatic and interference layers could be used effectively on the film. Using such coatings, and assuming the high incident energy of 700 suns, the sail temperature and associated problems would be about the same as for the 0.1-AU perihelion solar-sailing case. However, if a laser source of sufficiently high power (20 megawatts average) could be built and placed in orbit, the spacecraft could attain a v_∞ of up to 200 km/s.

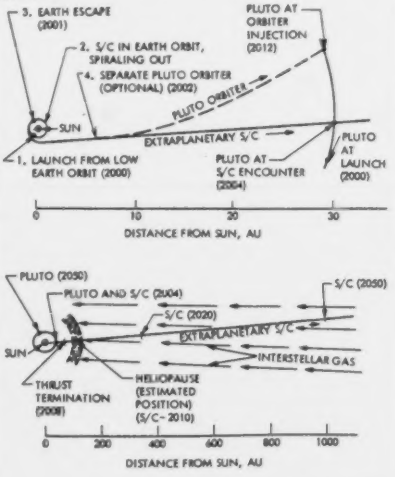
Fusion as well as fission reactors were considered for nuclear-electric propulsion (NEP). Rough calculations for a fusion system, based on today's limited knowledge, indicate a 30% improvement in v_∞ over a fission system, but at the expense of much larger spacecraft mass (perhaps orders of magnitude larger)[9] as well as probably a prohibitive cost. Moreover, net energy production by controlled fusion has not yet been attained, and development of an operational fusion propulsion system for a year-2000 launch is highly improbable. Collection of hydrogen en route to refuel a fusion reactor[12] stands even further in the future, and it may well never be feasible.[13]

NEP systems using fission have already been the subject of considerable study and some advanced development.[14,15] Designers have more confidence that NEP systems can meet the performance requirements than the other options examined. Preliminary calculations showed that one NEP stage could yield a v_∞ above 100 km/s.

After weighing the pros and cons of these several propulsion options, we chose fission NEP for the baseline extraplanetary spacecraft and its mission.

Mission Design: Both scientific goals and spacecraft performance shaped characteristics of the extraplanetary mission.[1,2]

F-1 TRAJECTORY OF EXTRAPLANETARY SPACECRAFT
For baseline interstellar precursor mission. Expanded-scale Earth-Pluto portion includes separation and trajectory of optional Pluto orbiter. Time of major mission events is based on launch in year 2000.



T-1 MASS AND PERFORMANCE ESTIMATES FOR BASELINE EXTRAPLANETARY SPACECRAFT
For single- and two-NEP-stage versions, including the optional Pluto Orbiter; I_{sp} and propellant loading not yet optimized.

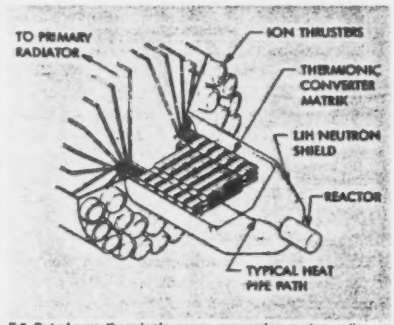
Allocation	Mass, kg	
Spacecraft (without power and propulsion)	1200	
Pluto orbiter	1500	
Propulsion, dry (NEP, 500 kw_e)	8500	
Propellant (Hg): spiral from Earth orbit	2100	
heliocentric trajectory	18100	
Propellant tankage	600	
Total mass in Earth orbit, 1 stage	32000	
Booster stage (2 × 500 kw_e NEP)		58000
Total mass in Earth orbit, 2 stages		90000
Performance	**1 Stage**	**2 Stages**
Distance at booster burnout, AU	—	8
V_∞ at booster burnout, km/s	—	25
Time from launch to booster burnout, yr	—	4
Distance at spacecraft NEP burnout, AU	65	155
V_∞ at spacecraft NEP burnout, km/s	105	150
Time from launch to spacecraft NEP burnout, yr	8	12
Spacecraft distance in 20 yr, AU	370	410
Spacecraft distance in 50 yr, AU	1030	1360

Most of the scientists consulted favored a trajectory that would take the spacecraft out of the solar system as rapidly as possible. This would provide a relatively early opportunity to obtain measurements of the heliopause and the interstellar medium. It would also place the spacecraft at a large enough distance from Earth to permit optical determinations of stellar parallax within a reasonable period after launch. Pluto observations were also deemed desirable.

Salient spacecraft performance goals includes a 20-year design lifetime and a 50-year extended lifetime, a heliocentric excess velocity of around 100 km/s, appropriate science instrument pointing provisions, and a telecommunications system adequate for data transmission and command reception to a distance of 1000 AU.

In the resulting mission design (F-1) the spacecraft, with or without a second NEP stage, would be placed into a low Earth orbit by some descendent of the Shuttle (an alternative would be the use of two or more Shuttle launches and space assembly of the vehicle). NEP then drives the spacecraft through an Earth-escape spiral. Thrusting continues as the spacecraft flies along a heliocentric-orbit trajectory. It takes a long "burn" to attain the required v_∞: about 8 years with a single NEP stage and close to 12 years with two. The thrusters would be shut off during Pluto flyby as well as during other periods when the exhaust would interfere with scientific measurements. Enough propellant would be retained after the main period of propulsion to permit using thrusters for attitude control (unloading the reaction wheels). The reactor would be kept operating at low power for this purpose as well as for keeping non-propulsive spacecraft subsystems operating during the whole mission.

The spacecraft heads toward the incoming interstellar gas. By coincidence, Pluto will be very close to the selected trajectory during the 2000-2005 period. This makes an enroute Pluto encounter feasible. The encounter could be just a flyby; or, if more information about Pluto is to be obtained, a Pluto orbiter could be carried by the main (extraplanetary) spacecraft and be separated early in the mission. The Pluto orbiter would be a full-up spacecraft, with sufficient chemical propulsion to handle midcourse corrections, approach, and orbit injection. It would carry a full complement of science instruments (including imaging), would be powered by RTGs (radioisotope thermoelectric generators) and would communicate directly with Earth. Its flight time to Pluto would be about twelve years and its approach velocity at Pluto would be about 8 km/s. Since the extraplanetary spacecraft would fly by Pluto about eight years before the Pluto orbiter reaches it, the flyby data could be used for orbit optimization.



F-2 Out-of-core thermionic power conversion system relies on about 100 heat pipes to transfer heat generated by the nuclear reactor to thermionic converters (six per heat pipe). After conversion of thermal to electrical energy, the remaining heat is carried to the primary radiator for dissipation. Illustration after Phillips and Pawlik.[19]

Some thought was also given to an additional mission, suggested by some of the scientists contacted, in which a spacecraft similar to the baseline vehicle (but without Pluto orbiter) would be flown outward parallel to the solar axis, a trajectory essentially perpendicular to that of the heliocentric baseline mission. Such a mission would require somewhat more propulsive energy to attain the same v_∞. Thus a Jupiter swingby might be helpful

in it. A second NEP stage would be more advantageous for this mission than for the baseline mission.

Mass and Propulsion System: T-1 gives spacecraft mass and performance estimates. A mass of 1200 kg was allocated to nonpropulsive, nonpower-generating portions of the spacecraft; this covers all the usual subsystems and structures such as booms, electronics bus, orbiter supports, and NEP interfacing. Science instruments, scan platforms, and telecommunications equipment would weigh more than for typical outer-planet missions studied by JPL. An allowance was included for radiation shielding. Telecommunications could require as much as 1 kw of electrical power; nonpropulsive spacecraft power was thus set at about 1500 w.

The Pluto orbiter's mass, 1500 kg, includes about 1000 kg of chemical propellant representing a ΔV of 3500 m/s (allowing a good capture orbit at Pluto).

The NEP—a 500-kw_e system with 20% conversion efficiency—would consist of a nuclear reactor, reactor controls, a coolant system, radiation shielding, thermionic converters, radiators, power conversion and conditioning, and ion thrusters (see F-2). Such a system would have a dry mass of about 17 kg/kw_e for an exhaust velocity of 100-140 km/s. We chose mercury propellant because of its high liquid density (13,600 kg/m^3) and its very effective gamma-ray shielding. An NEP booster would employ two of these 500-kw_e units.

The reactor would be designed for a fuel burnup equivalent to 200,000 hr at full power, of which 70,000 (8 yr) would be at full power, and the remaining 130,000 hr at about one-third power (scaled linearly, equivalent to 390,000 hr, or 44 yr, of reduced power operation). Major improvements in reactor controls as well as adaptive control for power and propulsion functions will be required to attain such reactor operation.

The total initial mass in low-Earth orbit (32,000 kg without the second NEP stage) is larger than the currently established Shuttle payload limit (29,500 kg). However, a vehicle able to launch substantially heavier payloads should be available in the 1990s.[9] Hence, we assume the baseline spacecraft requires only a single launch. Space assembly would probably be required to add a second SEP stage.

Data Handling and Telecommunications: Establishing a reliable telecommunications link for an extraplanetary mission out to 1000 AU should, ideally, be based on technological advances anticipated to occur during the next twenty years. We believe developments will surely permit an X-band system with 40 w of transmitter power, a 15-m-diam spacecraft antenna, and a 100-m receiving antenna on Earth as a reference system, providing 100 b/s at 1000 AU. The 100-m antenna would be supplied by the NASA Deep Space Network (DSN).

For a mission lasting between 20 and 50 years, with relatively little happening most of the time, it would be unreasonable to expect continuous DSN coverage. For the long cruise periods a 1% coverage (8 hr per month) would probably be sufficient. This poses the need for onboard data processing (compression) and storage, with playback and transmission at a relatively high rate in brief periods. During heliopause encounter the coverage may have to be increased to as much as 8 hr per day. For Pluto flyby continuous coverage would probably be required. Coverage for the Pluto orbiter would be either 8 or 24 hr/day for at least some of the mission of the orbiter.

Onboard adaptive data-acquisition, data-processing, and data-compression techniques would be employed to minimize the rate of transmitting data from the spacecraft. Even with these features, data rate should average 20-40 b/s. With 1% coverage, this corresponds to a transmitted data rate of 2-4 kb/s. Several approaches could provide this transmitted data rate:

—More spacecraft transmitter power (500 to 1000 w).

—A 300-m-diam receiving antenna located on an

T-2 DATA RATES FOR TELEMETRY SYSTEM ALTERNATIVES
Transmittable data rates are shown at distances of 1000 AU (50-yr mission), 400 AU (20-yr mission), 150 AU (worst-case assumed end of heliopause), and 31 AU (Pluto); noise temperature of 10 K for X-band, 14 K for K-band.

Option	Improvement over baseline, dB	Data rate × range^2, b/s-AU^2	Data rate, (b/s)			
			1000 AU	400 AU	150 AU	31 AU
Reference system (40 w, X-band, 100-m receiving antenna)	—	1×10^6	1×10^2	6×10^2	4×10^3	1×10^5
More xmtr. power (500-1000 w)	10-15	1×10^9	1×10^3	6×10^3	4×10^4	1×10^6
300-m ODSRS antenna:						
At X-band	13	2×10^9	2×10^3	1×10^4	9×10^4	2×10^6
At K-band	17	5×10^9	5×10^3	3×10^4	2×10^5	5×10^6
More power plus 300 m ODSRS, X-band	23-28	3×10^{10}	3×10^4	2×10^5	1×10^6	3×10^7

Orbiting Deep Space Relay Station (ODSRS).[16]

—Transmission via K-band, instead of X-band, to the ODSRS.

T-2 shows the improvements made possible by these options.

Spacecraft Configuration: F-3 depicts a first-cut conceptual configuration of the extraplanetary spacecraft. We assumed a furlable "wrap-rib" design for the 15-m antenna. The annular feed for the antenna surrounds the power-processor radiator. This feed design allows transmission aft along the thrust vector and around the high-energy-particle stream from the ion thrusters.

The entire portion of the spacecraft aft of the antenna involves the NEP system, including the power processor. Some spacecraft equipment could be placed in the transition structure between the power-processor radiator and the antenna hub.

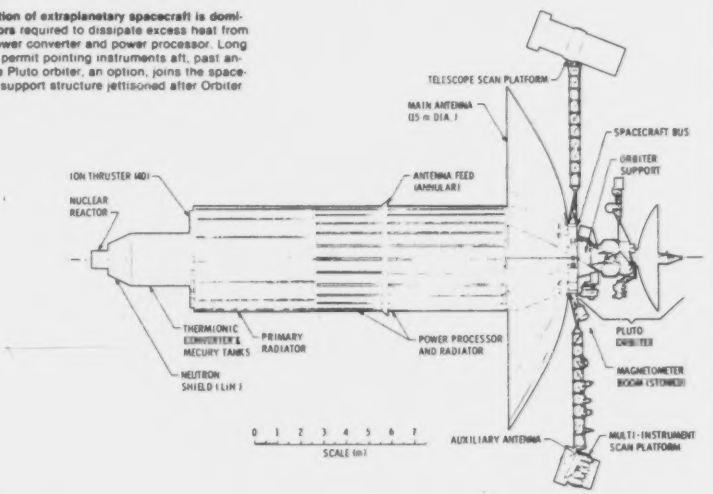
The spacecraft bus carries the electronics, including celestial sensors for attitude-control referencing. Reaction wheels and ion thrusters control attitude. The outer of two concentric sets of thrusters would be gimballed for this purpose.

Support structures for the Pluto orbiter and the two deployable science booms are mounted to the spacecraft bus. The orbiter would be separated from the forward end of its support (the structure later being separated from the bus and jettisoned).

The extendable magnetometer boom, in its stowage canister, attaches to the boom-support structure. Sensing elements of the vector magnetometer, used for magnetic field measurements and mounted at and near the boom tip, thus ride at a distance from the spacecraft-induced magnetic field when the boom is extended. Other scientific equipment (included on a "strawman" list of potential science instruments[2]) either ride on a boom or on one of two scan platforms. The boom-mounted instruments measure plasma properties and electric fields, characteristics of interstellar dust and gas (mass spectrometer), and low-energy cosmic rays.

The telescope scan platform carries a single instrument, the long-focus TV camera, which has a 1-m-diam objective 3.5 m long. A short-focus camera, also with a 1-m-diam objective, rides the multi-instrument scan platform. Both platforms can be rotated about two axes.

Five additional instruments (from the "strawman" list) are mounted to the camera's support clamp on the multi-instrument platform: a microwave radiometer (to sense radiation temperature), a gamma-ray transient detector, an ultraviolet/visible spectrometer, and two instruments used mainly during Pluto flyby—an infrared radiometer and an infrared spectrometer. This platform also carries an auxiliary antenna, possibly articulable independently; it would be used during early mission phases when the main antenna does not point directly at Earth. Antennas needed for a radio-as-



F-3 Configuration of extraplanetary spacecraft is dominated by radiators required to dissipate excess heat from NEP reactor, power converter and power processor. Long science booms permit pointing instruments aft, past antenna edge. The Pluto orbiter, an option, joins the spacecraft through a support structure jettisoned after Orbiter separation.

tronomy/plasma-wave receiver would extend from the spacecraft bus.

The Pluto orbiter (F-3) has a configuration based on the Galileo spacecraft (Jupiter orbiter with probe) now being developed by JPL. Its instruments would include a TV camera, a gamma-ray spectrometer, and many of the instruments also carried on the extraplanetary spacecraft.

Developments Needed: Several areas of technology would require significant development to enable an interstellar precursor mission with a launch in the year 2000. These include primarily design and fabrication techniques that can provide a 20-50-year lifetime for spacecraft subsystems and components (including moving parts such as bearings) and application of quality assurance and reliability prediction methods utilizing test times much shorter than the intended lifetime. Current low-level development efforts in NEP systems would have to be expanded to provide a long operating life at full power and a much longer operating life at reduced power. For solar or laser sailing to be considered for such a mission, appropriate materials and systems would need to be developed. Antenna-pattern problems associated with the annular feed would need to be investigated; and optical (laser) communications instead of RF should be looked into as a possible alternative. Some science-instrument development would be needed, and instrument compatibility with NEP would have to be examined.

We have the motive for this: man reaching out to a star. A mission out of the planetary system, with launch about the year 2000 could provide valuable scientific data as well as test some of the technology for a later mission to a star. Most critically needed will be technology that can yield a 50-yr spacecraft lifetime and a long-life NEP system.

Acknowledgement

Many persons contributed to the ideas expressed in the article. We wish to thank especially the other members of the JPL study team which worked out the conceptual design for the interstellar precursor mission and the extraplanetary spacecraft: C. V. Ivie, J. C. Lewis, R. Lipes, J. W. Stearns, L. D. Stimpson, and P. Weissman. We also thank W. F. Carroll and C. Uphoff for their contributions regarding solar and laser sailing. This work was sponsored by the Study, Analysis and Planning Office of the NASA Office of Aeronautics and Space Technology under Contract NAS 7-100.

Effective Planetary Exploration at Low Cost

By JESSE W. MOORE
NASA Office of Science and Applications
Earth and Planetary Exploration Div.

Reproduced from Moore, Jesse W. Effective planetary exploration at low cost. Astronautics & Aeronautics, v. 20, Oct. 1982: 28-38, 52 with permission of the copyright holder Aerospace America.

In NASA's planetary exploration program for the '80s the Galileo mission, now in its fabrication stage, may well be the sole successor to the Mariners, Pioneers, Vikings, and Voyagers of the '70s. Funding for the planetary program has reached an all-time low of less than a third of its peak, and five budget years have passed since the start of Galileo.

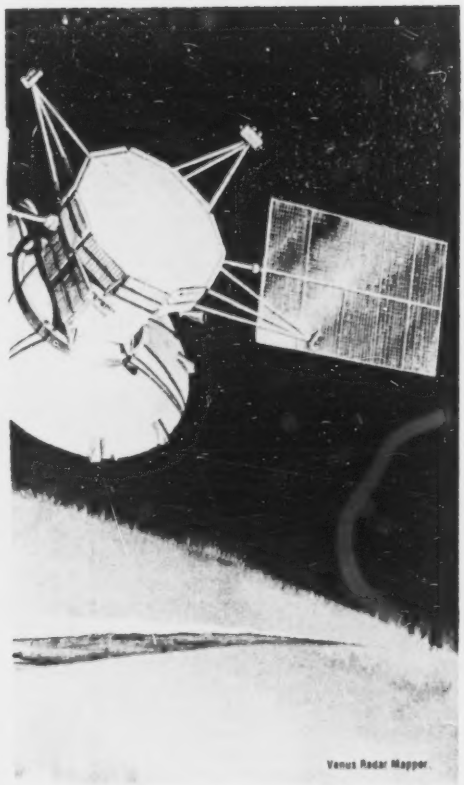
Turning this downtrend around, most would now agree, requires finding ways of making solar-system exploration as inexpensive and cost-effective as possible. This has been an aim of the Solar System Exploration Committee (SSEC), an ad hoc advisory group working for the past two years (see box). With the support of NASA Ames Research Center and the Jet Propulsion Laboratory (JPL) it has examined various ways to reduce costs for planetary missions. This article describes efforts to reduce costs of planetary missions. Approaches drawing in good part on existing hardware, but also including new technologies, hold great promise for revitalizing the planetary program.

Background: The significance of relatively low-cost missions presently under study can only be appreciated by looking back at the course of the planetary program. It began opportunistically, taking as ready and obviously alluring targets the planets Venus and Mars. The first four U.S. deep-space projects achieved two flybys of Venus and three of Mars. The spacecraft were derived from the lunar-exploration Rangers.

Meanwhile, the Apollo manned lunar landing program emerged. Apollo eclipsed brilliant successes of unmanned Lunar Orbiters and Surveyors. Direct sample return by Apollo crews proved the most comprehensive and powerful technique for planetary exploration, and the laboratory analyses used to study the lunar samples were immediately applied to large numbers of planetary samples (meteorites of unknown parentage) in museums. The combined results give us far-reaching knowledge about the origin of the solar system.

Telescopic techniques progressively opened another important avenue to exploration of the solar system. Planetary astronomy has done much science that might otherwise have called for spacecraft reconnaissance and has surveyed areas still unexplored by spacecraft, the comets, and asteroids.

As Apollo ended, planetary exploration surged into an extraordinary pioneering period. The missions of the '70s pushed inward to Mercury and outward to Jupiter and Saturn, and they took on the extraordinary challenge posed by the search for life



Venus Radar Mapper

Sticking to the main scientific objectives, using derivative designs and hardware, and strictly limiting modifications will permit a relatively inexpensive planetary program of sweep and effectiveness

on Mars, a goal calling for technical innovation of the highest order.

Marvelous but very expensive machines wrote the first chapter in planetary exploration. Deep-space mission results were combined with telescopic discoveries and lunar-sample and meteorite analyses to create a broad, solid base of experimental data and an array of testable models of solar-system origin and planetary evolution. Thus the development of a *systematic* scientific strategy for exploration of the solar system became possible.

Beginning in 1974 the Space Science Board (SSB) of the National Academy of Sciences took on this task. To NASA it recommended strategies for exploration of the outer planets, the inner planets, and the primitive bodies—the comets and asteroids. The apparent absence of life at the two Viking landing sites on Mars caused the SSB to recommend against direct follow-ups to the Viking biology experiments, thus creating a major branching point for the planetary program.

SSB Recommendations: As a general strategy the SSB recommended that exploration move forward on a *broad front,* beginning with reconnaissance to all accessible planetary bodies, progressing to exploration of selected planets, and intensively studying a limited number of bodies. It recommended reconnaissance of parts of the solar system "where ignorance is greatest and the opportunity for new discovery is large."

The SSB set out in some detail the questions that should be addressed by planetary missions and provided guidance about priorities. Achieving all the SSB goals would call for a powerful program of some diversity—one that would include the whole range of automated exploration techniques: remote sensing orbiters, atmospheric probes, surface landers, mobile labs, and sample-return spacecraft.

Omitting the latter two permits a technologically much less ambitious program within available launch capability (the two-stage Inertial Upper Stage (IUS) or the Centaur) and using approaches successfully demonstrated.

Options for Missions: On this basis, formulating mission strategy can be reduced in large part to a question of cost-effectiveness in missions of a well-understood character. The strategy could use three different approaches—

—Use of existing space hardware (including Galileo's).

—Modification of "production-line" spacecraft developed by aerospace companies for scientific and commercial use in Earth orbit.

—Development of a new modular spacecraft allowing a series of missions beyond the orbit of Mars.

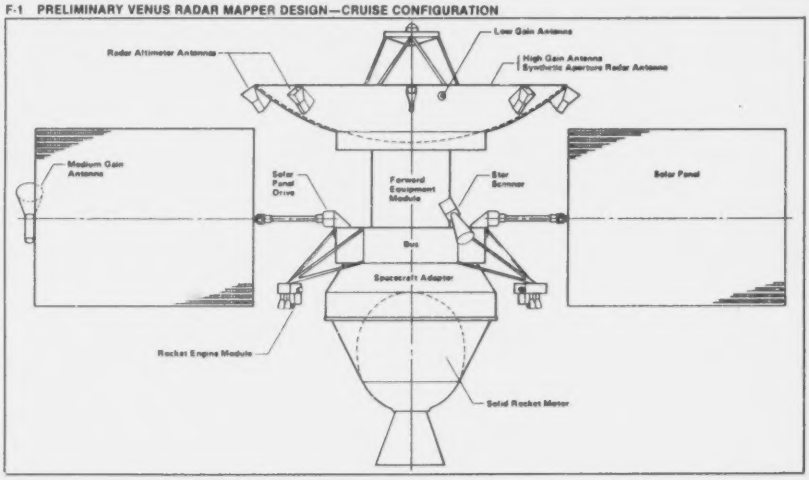
The Venus Radar Mapper (VRM): Already endorsed by the Solar System Exploration Committee and by the Space Science Board and an attractive candidate new start for FY84, the VRM mission fits the first category.

Usually a planetary project begins with fundamental scientific questions. These set requirements of the mission, spacecraft, and sensors. Ordinarily, many special subsystems must be developed to meet the requirements. This makes project costs high.

VRM's project constraint of low cost necessitated a different approach. Practices consistent with previously established overall strategies for the exploration of the inner planets defined VRM—making fullest possible use of proven designs and existing hardware, limiting mission objectives, and trading off objectives with the requirement to use existing designs. A willingness to reduce a requirement to permit use of an existing design proved essential to low cost for VRM.

The prime objectives could be met by a spacecraft synthesized largely from existing designs. Using the Voyager antenna for both the SAR (Synthetic Aperture Radar) and the telemetry link typifies the trade-offs made. Image quality and swath width were compromised by this selection. The downlink data rate was constrained by the antenna, an X-band using open-loop pointing. A further constraint was the desire to avoid Deep Space Network (DSN) development costs by restricting the data rate. Together, these constrained the quantity of data and SAR resolution. The Command and Data System (CDS), a Galileo subsystem, likewise imposed limits in data and command rate. Nevertheless, the preliminary system assessment, performed by Hughes Aircraft, confirms that, while the compromises do not allow full advantage to be taken of SAR, they yield a design that meets all requirements.

F-1 PRELIMINARY VENUS RADAR MAPPER DESIGN—CRUISE CONFIGURATION



A spacecraft design formulated from these and other trade studies can meet broadly endorsed mission objectives at minimum cost. F-1 shows a preliminary spacecraft layout developed by Martin Marietta and JPL based on tradeoff analyses performed to date. It maximizes use of hardware and software designs from the Voyager, Galileo, and International Solar Polar (ISPM) missions. Simplicity is obtained through shared use of the fixed high-gain antenna and by limiting articulation to single-axis rotation of two solar arrays. The spacecraft embodies much existing equipment and design:

- It uses the CDS from Galileo with a minor modification (e.g., a timing circuit to produce the required telemetry rates and CDS flight software with minor modifications).

Solar System Exploration Committee (SSEC) Translates Scientific Strategy into Missions

The SSES, an ad hoc committee of the NASA Advisory Council, was formed in 1980 to "translate the scientific strategy developed by the Space Science Board of the National Academy of Sciences into a realistic, technically sound sequence of missions consistent with that strategy and with resources expected to be available for solar system exploration... to focus its initial efforts on those missions planned for initiation in FY84 and then extend its considerations as far into future as possible."

The SSEC has the following membership:

Noel Hinners, Chairman
Geoffrey A. Briggs, NASA, Executive Director
Arden Albee, CalTech
Kinsey Anderson, UC-Berkeley
James Arnold, Univ. of San Diego
Charles A. Barth, Univ. of Colorado
Thomas Donahue, Univ. of Michigan
Lennard A. Fisk, Univ. of New Hampshire
Harold P. Klein, NASA Ames Research Center
Eugene Levy, Univ. of Arizona
James Martin, Martin Marietta Corp.
Harold Masursky, U.S. Geological Survey
David Morrison, Univ. of Hawaii
John E. Naugle, Fairchild Corp.
John Niehoff, Science Applications Inc.
Tobias C. Owen, SUNY/Stony Brook

The initial recommendations of the SSEC should have been formulated by the end of last month. A further year of study directed at the definition of additional options for planetary exploration is anticipated.

• The attitude and articulation control subsystem is structured around the Galileo's processor, memory modules, and power supply. Inertial-reference-unit design has been flight-proven by several programs, and the star scanner is the same model used on the Boeing IUS. The Sun sensors and associated electronics are unmodified flight-proven designs, and the reaction wheels are of NASA standard design.

• The electrical power subsystem employs two single-axis articulated solar arrays using flight-proven solar cells on conventional substrates. Related parts come from Galileo. The power control unit and shunt regulator are flight-qualified hardware designs from an Air Force satellite. The two 20-ah batteries are of NASA standard design.

• The telecommunications subsystem uses the 3.7-m Voyager high-gain antenna, two Viking low-gain antennas, and a single Mariner medium-gain antenna. ISPM (residual) traveling-wave-tube amplified assemblies serve X-band high-rate communications. NASA standard deep-space transponders are used with a Voyager control unit. Flight-proven switches and filters isolate and switch circuits.

• The thermal-control subsystem uses flight-proven louvres, multilayer blankets, and heaters.

• A Star 48 solid-propellant rocket motor (SRM) powers orbit insertion at Venus. Four residual (178-N thrust) hydrazine monopropellant engines make trajectory-correction maneuvers. Orientation during the SRM thrust is controlled by these four engines augmented by four 445-N engines and four 22-N engines, all of which have extensive flight history. Twelve (residual) 0.9-N thrusters from Voyager dump momentum through the mission. The propulsion subsystem is operated in a blowdown mode from a single Shuttle auxiliary propulsion tank. Additional pressurant is stored in a small Galileo residual tank for a one-shot recharge prior to orbital injection at the planet. Flight-proven ordnance valves and latch valves isolate propellant tanks to meet the Shuttle safety requirements.

JESSE MOORE directs the Earth and Planetary Exploration Div. of NASA's Office of Space Science and Applications. After graduating from the Univ. of South Carolina in 1964 with an M.S. in electrical engineering he joined General Dynamics, where he worked on naval missile guidance systems. Between 1966 and 1978 Moore worked at CalTech's Jet Propulsion Laboratory (JPL) on guidance and control, advanced programs, and flight projects. Before assuming his present position he directed the Office of Space Science's Spacelab Flight Div.

The Venus Radar Mission retains as its primary goal a low-resolution (< 1000 m) map of the planet's surface, with additional gravity and altimetry mapping. By these hardware adaptations it should meet this objective for only $280 million (in FY83 dollars).

At its June 1982 meeting the SSEC endorsed this Venus Radar Mapping mission in the following statement:

"A principal scientific objective of inner solar system exploration is to understand the nature and evolution of the interiors, surfaces, and atmospheres of the Earth, Venus, and Mars. These three planets are of similar size and formed in the same region of the solar system, but have evolved to extremely different present states. In order to advance our knowledge of the formation and the evolution of terrestrial-planet surfaces, including Earth's, the next major step in exploration of the inner planets is the global reconnaissance of Venus's surface features to ascertain the processes and geologic history by which the surface has evolved. Because of the ubiquitous cloud cover on Venus, orbital observation with an imaging radar system is the only feasible approach. The SSEC reaffirms that an orbital imaging radar mission to Venus remains

of highest priority.

"Early in its deliberation the SSEC adopted the philosophy that in the present economic environment planetary missions cannot successfully be achieved without instituting a wide range of cost-cutting measures, acknowledging that scientific requirements might have to be tempered during this time to accommodate such measures. These measures include, for example, utilization of existing hardware, design and technologies, simplification of mission operations, and reduction of data rates and other spacecraft demands commensurate with essential scientific needs.

"The Venus Radar Mapper Mission, as presently conceived, has capitalized on this cost-saving approach. While reduced in scope from the original plan for the Venus Orbiting Imaging Radar Mission, the mission will reveal important information needed to continue our comparative studies of Earth, Venus, and Mars. Although global coverage and resolution are somewhat reduced, the Venus Radar Mapper Mission has included several adaptive features which are improvements over the earlier design. The SSEC strongly supports the Venus Radar Mapper Mission as a new start for FY84."

Low-Cost Outer Planet Probes: The first category of low-cost mission approaches includes not only the use of existing space hardware but also the hardware in production for the Galileo mission. Outer-planet missions being studied borrow heavily from the Galileo probe design. Science goals formulated in the light of Voyager results can be effectively addressed using minimal flyby missions with in situ sampling by atmospheric probes.

The principal science goals for entry probes in Saturn and Titan missions would be to determine the molecular and isotopic composition and structure of the atmospheres, the composition and structure of aerosols in them, and their sources of energy and associated organic chemistry.

Science goals for the probe-carrier and data-relay spacecraft include a determination of the physical nature of the surface of Titan, magnetospheric and

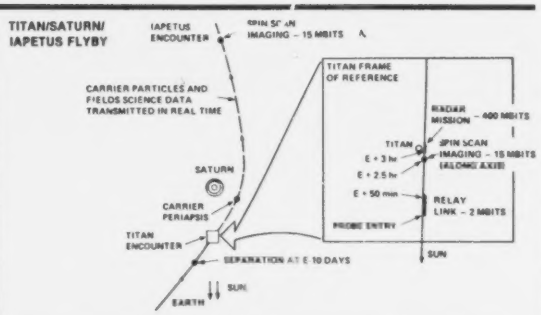
Probing Titan's Atmosphere

The proposed 1990 Titan Probe/Flyby mission commences with a Shuttle launch to Earth orbit during the March launch window. Either the Centaur upper stage or a three-stage stack of solid motors boosts the spacecraft from Earth orbit into the direct heliocentric transfer to Saturn. After a heliocentric transfer lasting about 3.5 yr, it reaches Saturn in August of 1993. The approach to Saturn is generally in a direction toward the sunlit face and toward the northern hemisphere 10-20° above the plane of the rings.

Using Earth-based radio doppler and ranging data, the carrier/probe spacecraft combination is directed toward a (probe) impact trajectory of Titan on the inbound hyperbolic fall toward Saturn. After its close encounter with Titan the carrier spacecraft will proceed on a trajectory past Saturn to a near encounter with Iapetus on the outbound leg of the hyperbolic flyby of Saturn. The appropriate position for Titan is thus in the direction of the Sun from Saturn.

Radio tracking and small propulsive maneuvers during the fall toward Saturn until ten days before reaching Titan allows the carrier/probe spacecraft to be targeted to a direct 90° impact with Titan with a one-sigma dispersion of about 500 km. At this point the probe is released and the carrier spacecraft is deflected and slightly decelerated in order to miss Titan by 2000 km and lag behind the probe by about 10,000 km to aid relay communication as the probe descends.

At 5000 km above the edge of the atmosphere of Titan, pre-entry science measurements will be started on four exterior mounted instruments that sample the upper atmosphere. Measurements continue to an altitude of about 700 km, where atmospheric heating begins to degrade instrument performance, at which time the externally mounted instruments are actively separated from the body of the probe.



The probe undergoes atmospheric entry heating and deceleration from an entry speed of about 10 km/sec to sonic speed at an altitude of about 100 km. The maximum deceleration will be about 24 *g* (Earth). Shortly thereafter, a parachute is deployed to extract the descent module from the forward heat-shield and thus expose the science instruments to the atmosphere. The five science instruments of the descent payload would be atmospheric structure instrumentation (ASI) with accelerometers and temperature and pressure sensors, a neutral mass spectrometer, a gas-chromatograph, a nephelometer to measure particle-size distribution in clouds, and a descent imager to take both upward and downward light-intensity measurements and to image the surface from an altitude of about 8 km.

During closest approach a synthetic-array/real-array hybrid imager mounted on the spinning carrier spacecraft makes a single image of 17% of the surface of Titan. Surface resolution will average about 6 km. In addition, radio occultation measurements of the atmosphere of Titan will be made.

Following the encounter with Titan, a small propulsive maneuver adjusts the trajectory of the carrier spacecraft to proceed to an encounter with Iapetus (less than 100,000 km) for making spin-scan visual images of the anomalous light and dark faces of that satellite. Surface resolutions of better than 10 km appear feasible.

high-energy-particle science, Saturn ring and system-dust measurements, and imaging reconnaissance of satellites poorly viewed by Voyager 1 and 2 (e.g., Iapetus or Phoebe). See above for a brief description of the Titan probe mission.

Following missions to Titan and Saturn, the low-cost outer-planet-mission set would be rounded out with flybys and probes to Uranus and Neptune.

Such missions would retain program continuity and science value by—

—Requiring each mission to focus on a limited set of science objectives.

—Using spacecraft with a very high degree of hardware component or design inheritance from existing spacecraft.

—Strictly adhering to a design-modification philosophy which requires minimum changes.

—Treating the outer-planet-mission set as a *single project* that postulates efficient "block-buy" of hardware components.

Under contract to NASA-Ames, Hughes Aircraft studied this approach by drawing on Galileo to meet SSEC goals. F-2 shows the probe concept used. It is very similar to the Galileo probe. The carrier spacecraft reflects a design concept proposed to NASA for Galileo at the time the agency considered splitting the mission into separate probe and orbiter launches. The spin-stabilized spacecraft has a despun steerable high-gain antenna with a separate, fixed probe-relay link antenna. It uses much hard-

ware from other NASA spacecraft and various commercial communication-satellite programs.

The probe follows Galileo design for Saturn and Titan with very few changes (T-1). The heatshield subsystem of the deceleration module causes the principal difference in weight. Galileo must handle a relative entry velocity of about 47 km/sec as compared to 29 km/sec for Saturn and only 10 km/sec for Titan. The structural subsystem remains unchanged and thus offers a large margin of safety. The communication and power subsystems would also be unchanged, resulting in a very large link margin at Titan, where the communications range between the probe and carrier is relatively small. A small modification allows jettisoning the parachute from the descent module (not done on Galileo) to reach the water clouds on Saturn at a pressure level of 10 bars and to descend to the surface of Titan in a reasonably short time.

The instrument complement for Titan would be changed to include a gas chromatograph (GC) to analyze organic molecules. Since the data rate and command structure of the probe would be unchanged, and since shelf space is required to mount the GC, two current Galileo experiments must be removed, possibly the helium abundance detector and the lightning and radio-emission detector. Finally, the Titan probe would add an externally mounted pre-entry science package to sample the upper atmosphere.

SSEC-guided study effort over the past year supports such hardware and design choices for meeting science objectives. Several upper stages can be used to launch such missions with the Shuttle. Centaur or a three-stage stack of existing solid motors (two SRM-1s and a STAR 48) allow direct missions about 3.5 yr long to Saturn and then Titan. Trip times to Saturn/Titan of about 6 yr are possible with the two-stage IUS and a STAR 48 or a two-stage stack of SRM-1s.

The SSEC believes a sequence of outer-planet missions concentrating at first on Saturn and Titan makes effective use of Galileo inheritance and available launch opportunities. This sequence includes a 1990 Titan probe/flyby, a 1991 Saturn probe/flyby, a 1992 Neptune probe/flyby (Jupiter swingby), and a 1993 Uranus probe/flyby (Jupiter swingby).

The first mission would cost about $190-270 million (constant FY83 dollars with a 20% contingency and not including launch vehicle or operations costs) depending upon the amount of scientific equipment carried over and above the basic probe payload. Subsequent missions would cost significantly less as a result of high inheritance.

Closer to Earth—a New "Pioneer" Class: Another category of lower-cost missions seeks to benefit not only from "heritage," but also from modification of existing "production-line" spacecraft developed by aerospace companies for both scientific and commercial applications. The missions would be tightly focused in terms of science goals and instrument payloads. As much as possible they would use modifications of Earth-orbiting spacecraft (in production at a time compatible with the planetary program start). R&D costs for the spacecraft would thus be virtually nil. Hardware would already be flight-qualified and might even be Space Transportation System (STS)-qualified.

Moreover, keeping structural changes to a minimum by judicious placement of instruments and instrument appendages on the spacecraft and adding a despun instrument platform would reduce modification costs. Picking a spacecraft in production for several years (as expected through drawing on communication-satellite programs) would likewise radically cut program costs.

We estimate costs for these missions to be $75 million to $150 million.

NASA has asked the Solar System Exploration Committee to verify this picture for a number of missions identified as candidates (T-2), including orbiters, probes, and rendezvous spacecraft to Mars, Venus, the Moon, and nearby asteroids. During the past year, scientific objectives and mission requirements have been developed for all of these missions by SSEC subcommittees in concert with engineers and scientists from NASA-Ames and JPL. The first four missions in T-2 have been extensively studied by private companies under contract ("Phase A" mission studies).

A prime objective of these studies has been to judge whether mission costs can indeed be kept within the "Pioneer"-class by selective scientific objectives and adaptations of Earth orbiters.

The studies also defined the benefits and limitations of this concept. Surprisingly to some, modest

T-2 "PIONEER"-CLASS MISSIONS AND OBJECTIVES

Target body	Mission names	Objectives
Mars	Climatology orbiter	Seasonal volatiles history, climate
Mars	Aeronomy orbiter	Survey upper atmosphere and solar wind interaction, magnetic field
Mars	Geoscience orbiter	Surface composition, magnetic field, topography, gravity
Moon	Geoscience orbiter	Surface composition, topography, gravity
Mars	Penetrator network	Bulk composition, structure, weather
Venus	Atmosphere probe	Atmosphere composition
Near-Earth asteroids	Rendezvous	Composition, density, morphology

T-3 MARS AND MOON ORBITERS

Instruments	Measurement objectives
A. Mars Climatology/Geoscience Orbiter	
Gamma-ray spectrometer	Surface elemental composition; distribution of subsurface ice; thickness of polar caps; composition of polar laminae.
Multispectral mapper	Surface mineral composition; condensed CO_2 and H_2O.
Radar altimeter	Global figure and surface topography.
Atmospheric radiometer	Atmospheric water vapor, dust, condensate clouds, temperatures.
Tracking	Global gravity field and large-scale anomalies.
B. Lunar Geoscience Orbiter	
Gamma-ray spectrometer	Surface elemental composition.
X-ray spectrometer	Polar condensates.
Multispectral mapper	Surface mineral composition, polar condensates.
Radar altimeter	Global figure and surface topography.
Tracking	Global gravity field and large-scale anomalies.

modifications to existing Earth-orbiting spacecraft designs give good results at another planet. Some of the Earth orbiters examined (high-power geosynchronous communication satellites, for example) require only minor internal changes to power, attitude, and communications subsystems. Others need additional changes, such as larger solar arrays, new structure, and new data systems.

The Near-Earth Asteroid Rendezvous mission represents the higher end of the scale. Such missions are exploratory in every sense of the word, since we have not previously visited an asteroid. The first mission would thus have the following fairly comprehensive suite of instruments including moderate-resolution imaging: solid-state imaging, multispectral mapper, γ-ray spectrometer, X-ray spectrometer, magnetometer, and radar. These instruments would determine composition and bulk density, investigate surface morphology, and determine internal properties (including magnetization) of a diverse set of asteroids.

Main-belt asteroids would have first priority, but near-Earth ones would be targets too for both scientific interest and as potential sources of materials for use in space. The main-belt asteroids are more difficult to reach in terms of energy, and lie outside the range of environments (Venus to perhaps 1.8 to 2.0 AU) to which a spacecraft designed for Earth orbit can easily adapt.

The Mars Climatology/Geoscience Orbiter (MCGO) and Lunar Geoscience Orbiter (LGO, see T-2) have a good deal in common. Recognizing this, studies of them have been carried out in a combined manner. T-3 lists candidate instruments and measurement objectives for both.

The data-gathering phase of the two missions would be quite similar. Both would enter low circular polar orbits, allowing all regions of each body to be observed during the mission. The MCGO will go into a slightly retrograde orbit that would receives lower priority than detailed compositional mapping, the goal of MGO and LGO. To keep costs at a modest level it is necessary to keep the goals of the mission tightly focused and not drive the mission or spacecraft design by adding too many requirements on any one mission. Three spacecraft have been considered as candidates for these missions. TRW has studied the adaptability of Fltsatcom, a nadir-pointing geosynchronous communications satellite. RCA has studied the adaptability of both the Dynamics Explorer and the Tiros/DMSP. All appear to be adaptable, although each has virtues and drawbacks.

Fltsatcom, not being a data-gatherer in its original form, requires more modifications in its electronics than the other two. However, it is large and capable and has ample power to perform the mission. Dynamics Explorer is a scientific spacecraft and handles the lunar mission with little change. It needs more solar arrays for Mars, and that requires enlargement of the entire structure of the drum-shaped spacecraft. Tiros has more capability than really required.

Thus the results of studies made to date encourage us to believe that advantage can be taken of the large investments made by the aerospace industry for missions in the inner solar system.

Exploring the Moon and Mars with Earth Orbiters

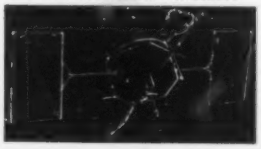
The Mars Geoscience Orbiter (MGO) is being considered for an FY85 start with a launch in July of 1986. The lunar mission is more flexible as to launch opportunity but would probably go at roughly the same time.

As noted in the article, the MGO and LGO missions are very similar. The difference in payload is that the LGO can carry an X-ray spectrometer; MGO does not since X-rays are absorbed by the planet's atmosphere. A radar altimeter provides a precise measurement of the global topography and tracking data and adds to knowledge of the global gravity field for both the Moon and Mars. Mineralogical data will be generated by a multispectral mapper for both.

By the addition of an atmospheric radiometer and optional ultraviolet instruments, the MGO can acquire a body of data that will yield better understanding of the past and present behavior of volatiles on Mars.

Conspicuous by its absence on both MGO and LGO is an imaging system. Unlike the asteroid mission, which requires imaging because we have never seen an asteroid in space (and also because of spacecraft guidance requirements at rendezvous), the Moon and Mars have already been mapped at optical wavelengths. Further high-resolution imaging thus

FLTSATCOM-BASED PLANETARY SPACECRAFT

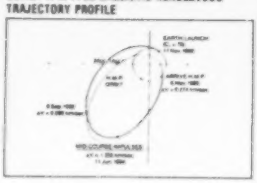


Rendezvous with HMP

Comet exploration deserves a high priority because comets may be the only obtainable source of the primitive material from which the solar system was formed. A rendezvousing spacecraft should observe a comet for several months at close range as its acticity builds up and dies down to map the physical and chemical properties of the nucleus.

Comet Honda-Mrkos-Pajdusakova makes a good candidate for a comet rendezvous mission. HMP is one of the brightest short-period comets. It has an orbital period of 5.3 yr and has been observed through six perihelion passages since its discovery. It exhibits both a well developed coma and an ion tail for 20 days before and after its closest approach to the Sun. The viewing geometry from Earth will be exceptionally favorable during HMP's perihelion passage in December 1995.

COMET H-M-P/95 BALLISTIC RENDEZVOUS TRAJECTORY PROFILE



Thus a 1995 rendezvous with HMP has been included in the Mariner Mark II study. The spacecraft would be launched by the Centaur stage from the Space Shuttle in November 1990. After two interplanetary propulsion maneuvers, it would rendezvous with the comet in November 1995, fifty days before perihelion passage. The post-rendezvous exploration might begin with a few close passes of the nucleus followed by retreat to a safe distance of perhaps 5000 km when the comet is most active. Once the dust hazard has subsided, after perihelion, the spacecraft would explore the comet's atmosphere and make progressively closer passes of the nucleus down to a 10-km mapping orbit. The mission might end with a touchdown on the nucleus.

precess in such a way as to maintain a constant angle between the orbit plane and the Sun-planet line. This provides optimum observations for multispectral-mapper and climatology experiments. Such an orbit would be desirable for the Moon as well but is not possible. The spacecraft operate in the final observation orbits for at least one Earth year to obtain enough γ-ray spectrometer data for accurate analysis. An extension to the mission is possible and probably desirable to study seasonal variation.

The major changes in the spacecraft, other than the payload differences noted, concern telecommunications systems and the orbit-insertion propulsion system. The much shorter communications range from the Moon allows an antenna of lower gain. Similarly, the propulsion requirements for the Moon are lower.

MCGO and LGO similarities suggest a single program to do both. Preliminary estimates indicate that both missions could be done for less than 150% of the cost of MCGO alone. Even more tantalizing is the possibility that both could be launched from the same Shuttle flight by the simple expedient of waiting in orbit for a few days between launches.

MCGO and LGO will operate roughly in the manner of an Earth-orbiting weather satellite. One listen-only station pass each day would broadcast that day's data to the DSN. Once a week a two-way link would be established to update the onboard computer and to provide data for orbit prediction. Otherwise the spacecraft would operate without ground intervention. Such practice will greatly reduce the cost of operations compared to previous, more adaptive missions.

Spacecraft would be modest in size and weight as well as in costs. Most payloads would occupy 6 m of Shuttle payload-bay length and weigh about 12,000 kg—take only a third of the payload-bay length and less than half of payload weight capacity, leaving the balance for other payloads.

All results from Phase A studies indicate that—

—Several types of Earth-orbiting spacecraft can be modified for conducting "Pioneer"-class missions at modest cost.

—Scientific objectives need not be compromised.

Members of the science community have reviewed this concept and these study results and have voiced support for such missions as a practical means of conducting useful science in these difficult financial times.

The Mariner Mark II (MMII) Concept: For certain deep-space missions, the third approach envisions developing both a spacecraft design which can be reconfigured at low cost from mission to mission and a design for a ground-support system that could be used for all the missions without reconfiguration. Design concepts draw heavily on earlier planetary missions but also include new technology expected to be available in the late '80s and the '90s. Modular subsystem design standards would support ready reconfiguration for various missions. The approach has been named Mariner Mark II. It encompasses the following types of missions:

- *Comet rendezvous.* Although the 1986 flybys of Halley will address many important questions about comets, a thorough investigation requires a rendezvous mission with a much longer period of observation at closer range. The choice of targets for a comet rendezvous is limited to short-period comets in low-inclination orbits.
- *Comet-sample return.* It is possible to sweep up

cometary gas and dust with a spacecraft that passes through a comet's atmosphere at high velocity and then to return that sample to Earth for analysis. Studying a single comet by simultaneous rendezvous and sample return would improve scientific study.

- *Main-belt asteroid tours.* A Mars gravity assist could send a spacecraft into the asteroid belt. Once there, a single spacecraft can rendezvous with two asteroids in succession or combine a rendezvous of one asteroid with flybys of several others.
- *Saturn orbiter.* A spacecraft in orbit around Saturn can use close flybys of the satellite Titan to adjust its trajectory to achieve a wide variety of orbits. Successive orbits can be used for close flybys of different satellites or for ring or magnetosphere studies.
- *Probe carriers.* An MMII spacecraft might also deliver probes to Titan, Saturn, Uranus, or Neptune. The probes would be the same as those described earlier, but the MMII carrier would allow more sophisticated mapping at visible, infrared, or radar wavelengths.
- *Mars orbiter.* Although the requirements for a Mars orbiter do not drive the MMII design, MMII could execute an excellent Mars geochemical mapping and climate studies mission.

To carry out such missions, the MMII spacecraft must be launchable by either a Shuttle IUS or a Shuttle Centaur. It must have a post-launch propulsion capability of up to 3 km/sec (up to 4 km/sec for some main-belt asteroid tours), operate for periods of up to 8 yr (10-12 yr if a Neptune mission is included in the set), communicate over distances as great as 11 AU (30 AU for Neptune), and operate over a range of solar distances from 1 to 10 AU (0.34 AU if the comet mission is an Encke rendezvous and up to 30 AU for a Neptune mission). Both the onboard optical navigation required for some missions and the scientific observations argue a three-axis stabilized platform with a pointing accuracy of 2 mrad. Data rates of 10-30 kbps are required, as is on-board data storage.

F-3 illustrates the modular, reconfigurable spacecraft design being considered for MMII. The central module supports the external modules and houses the spacecraft electronics and other assemblies that do not require external mounting.

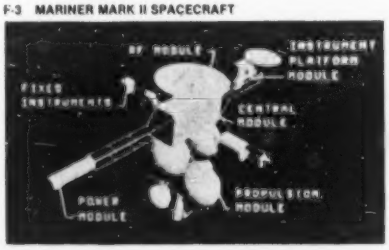
The radio-frequency (RF) module includes a body-fixed high-gain antenna together with its feed and receiver. The antenna size can be changed from mission to mission.

The power module would accomodate either a radioisotope thermoelectric generator (RTG) or a solar panel. An RTG is the power source of choice for the outer-planet missions, which must operate at great distances from the Sun. However, because an RTG is a source of radioactivity, it cannot be used on spacecraft that carry gamma-ray spectrometers for measuring the composition of the target body by analysis of the low-level flux of gamma rays which it emits naturally. For such missions, the power source would be a solar panel.

The propulsion module provides both the impulse for trajectory changes (ΔV) and the reaction control required for maintaining the proper orientation of the spacecraft. (F-3 shows the number of tanks corresponding to a $\Delta V = 2.9$ km/sec required for a comet rendezvous.)

The scientific instruments and attitude-control

F-3 MARINER MARK II SPACECRAFT



sensors are located either on the outside of the central module, on fixed booms, or on an articulated platform. This platform can rotate about either of two axes to allow the sensors on it to be pointed in almost any direction to view either reference stars or the target body. The final module (not shown in F-3) would be a probe or the Earth-return capsule for the comet sample-return mission.

F-4 illustrates how the spacecraft could be reconfigured from one mission to the next. F-4a could be used as a Saturn orbiter. F-4b shows a similar Mars orbiter, but having a solar panel rather than an RTG power source. The comet- and asteroid-rendezvous spacecraft would look like either 4a or 4b, depending on whether or not a gamma-ray spectrometer was part of the payload and how far from the Sun the spacecraft must operate. F-4c shows how the spacecraft might be configured for a probe-carrying mission. The propellant tanks required for interplanetary maneuvers would be jettisoned before the probe was released. The comet sample return spacecraft (F-4d) would be protected during its high-speed flight through the cometary dust cloud by a structure serving both as a bumper shield and sample collector. During flyby,

the power module and the scan platform would be folded back and hidden behind the shield.

The present concept assumes that the following new technology will be developed in time for use on MMII—

—A communications system which uses X-band frequencies on both the uplink and downlink.

—A bus-based data system with bus-interface modules to be placed in each subsystem or instrument to allow flexibility without changes to the data system.

—Fiber-optic rotation sensors (replacing conventional gyrosopes).

—A CCD-based star tracker that can image a field of stars or can be used in a closed-loop mode as a target-body tracker.

For a set of four or five missions in a decade, MMII costs should run between $175 and $325 million per mission (in FY83 dollars), *with an average spending rate of $100 million or less.*

Planetary missions, by definition, require Earth-escape launch power. That almost always exceeds the impulse requirements of Earth-orbital missions. Using the initial deployment impulse of geosynchronous missions as a basis of comparison, planetary departure impulses run some 30% higher for lunar missions, 50-75% higher for inner-planet missions, 75-100% higher for small-body missions, and possibly more than 200% higher for outer-planet missions. These launch requirements have always kept planetary missions at the forefront of launch-vehicle development issues.

Obviously, even our best efforts at reducing mission cost will not revive the solar-system exploration program if we do not have adequate launchers. On the other hand, we need to appraise realistically the pace at which NASA's STS can progress to meet planetary-mission requirements.

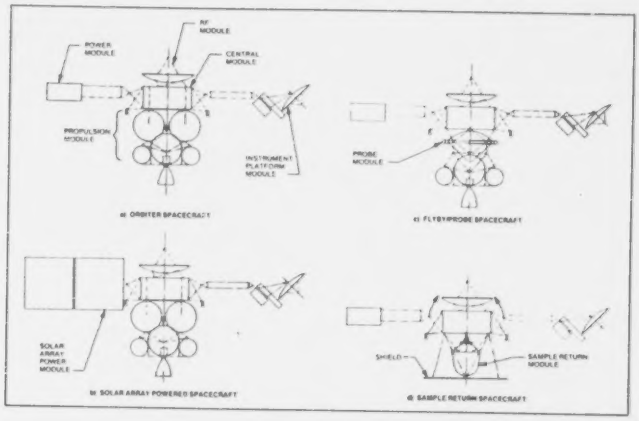
Upper stage requirements of the evolving new approaches can be briefly summarized as follows. The Pioneer-class missions using existing Earth-orbital hardware for inner-planet exploration will require less than IUS two-stage capability. Solid motors, such as the PAM-A and the large IUS motor, are attractive upper-stage candidates for these spacecraft. Additionally, payload-bay requirements are small enough that the Shuttle launch costs can be shared with a second mission. The remainder of the lower-cost approaches (e.g., Venus Radar Mapper, comet rendezvous, main-belt multi-asteroid rendezvous, outer-planet probe missions, and a Saturn orbiter) under consideration by the SSEC could, if necessary, be performed with the IUS two-stage plus a solid kick-stage motor.

Using the IUS two-stage for these projects may not, however, be the most cost-effective means. Many would then need indirect ΔVEGA transfers and infrequent planetary swingbys. The added cost of thus extending trip times and the inability to adjust flight schedules to a unique swingby requirement could easily off-set any cost advantage associated with basing MMII and outer-planet probe missions on the IUS two-stage.

Development of a Shuttle Centaur upper stage

(Continued on page 52)

F-4 MARINER MARK II CONFIGURATIONS



(Continued from page 38)

greatly improves the SSEC's ability to formulate an effective low-cost exploration program. Planning consequences include more comets from which to select a rendezvous mission, more asteroid-rendezvous targets per mission, more outer-planet launch opportunities, shorter trip times, and the possibility of dual-payload launches.

These advantages expand the scope of exploration, improve mission scheduling, and reduce operational costs. The SSEC has endorsed the development of a Solar Electric Propulsion Stage (SEPS) for similar reasons. Although a new direction in planetary exploration can be initiated without SEPS, the longer-term need for it persists. Certain comets and asteroid-sample returns, outer-planet satellite missions, and Mercury orbiters require the SEPS performance.

It is expected that the approaches to lowering the cost of planetary missions described here will be a central part of the program on missions recommended by the SSEC at the completion of its October 1982 study. The committee has also noted that opportunities to lower NASA mission costs, and to reap other benefits, are presented by planetary missions undertaken in cooperation with other nations.

Recommendations from the study will complete the first phase of the SSEC's activity. It will then take on a somewhat different character.

Emphasis to date in the SSEC's considerations has been set by economic conditions in our country and the near-term goals of NASA. Looking further ahead and presuming that the nation's economy will recover, space science should flourish again, leading to a need for a vigorous planetary program rather than one that is highly constrained. The content of such a program might include Mars missions of the Viking class (e.g., sample return and mobile laboratories) and precursor missions for a lunar base. Other missions of interest in an expansive planetary program include intensive study of the Earth-approaching asteroids in anticipation of their exploitation as resources and, as a new area of scientific investigation, Earth-orbital facilities to search for planetary systems about other stars.

When the nation's economic position permits, the more challenging missions could augment the "core" program recommended by the SSEC and return the planetary-exploration program to its former expansiveness.

A Program for Planetary Exploration

David Morrison and Noel W. Hinners

Summary. On the basis of a two-year study, the NASA Solar System Exploration Committee recommends a core program of planetary missions through the year 2000. By incorporating a number of cost-saving measures, an exciting program of planetary exploration can be achieved within a highly constrained NASA budget.

During the 20 years from the first Mariner flyby of Venus to the Voyager 2 encounter with Saturn, planetary exploration experienced its golden age. More than 40 robot spacecraft probed first toward the moon, Venus, and Mars, then ultimately to every planet known to ancient peoples, from Mercury to Saturn. Most of these spacecraft were launched by the United States, bearing names symbolic of their exploratory missions: Ranger, Surveyor, Pioneer, Mariner, Viking, and Voyager. The Soviet Union, the other nation to contribute to this era of discovery, focused its efforts more narrowly on the moon and Venus, but it too achieved remarkable successes. Within less than a generation, there was a revolution in our understanding of the solar system.

After such a brilliant beginning, it is natural to ask, What next? What new worlds remain to be explored? How do we best capitalize on our past successes? And perhaps most important in a time of constrained budgets, how do we justify continuing planetary exploration in the face of so many other worthy programs competing for federal research dollars?

As the 1970's drew to a close, planetary scientists asked these questions with increasing urgency. Following the 1977 approval for development of a Galileo orbiter and probe to Jupiter, there was increasing resistance to proposals for further initiatives in planetary exploration. Galileo was postponed repeatedly by launch vehicle delays, and its status remained precarious until the decision last August to adapt the powerful Centaur upper stage for the Shuttle (*1*). Meanwhile, the funds available to NASA for planetary exploration have dropped to 20 percent of their mid-1970's peak (*2*), and even the excitement of the Voyager encounters with Jupiter and Saturn and the once-in-a-lifetime opportunity to send a spacecraft to Comet Halley in 1986 (*3*) failed to reverse the declining support for planetary science.

The need for a fresh look at planetary priorities prompted the NASA administrator in late 1980 to appoint a special committee of the NASA Advisory Council to recommend an implementation strategy for planetary missions through the year 2000. This Solar System Exploration Committee (SSEC) (*4*) has now completed the first part of its task with the publication of a recommended core program of low- and moderate-priced missions. The program is intended to establish a stable basis for planetary science, so that scientifically exciting missions can be carried out within a framework of cost-saving engineering and management approaches. We report here the most important elements of this core program (*5*).

David Morrison is a professor of astronomy at the University of Hawaii, Honolulu 96822, past chairman of the Division for Planetary Science of the American Astronomical Society, and chairman of the NASA Solar System Exploration Committee. Noel W. Hinners, the committee's past chairman, is director of NASA Goddard Space Flight Center, Greenbelt, Maryland 20771, and president of the Planetology Section of the American Geophysical Union.

The Basis for Planetary Exploration

Planetary science is a relatively young discipline which has flourished in the United States primarily in response to the development of a deep space launch capability. Before the space age, planetary research was largely the province of a handful of astronomers, such as those working with Gerard P. Kuiper at the University of Chicago, while in the geosciences a few workers, notably Harold C. Urey, had begun to look at the meteorites as an important potential source of information on the formation of the solar system. Today, planetary science has more than a thousand full-time participants (*6*), drawn from backgrounds in physics, astronomy, meteorology, meteoritics, geology, geophysics, and geochemistry, and is supported by tens of millions of dollars in federal funds. Drawing on this multidisciplinary background and spacecraft data of unprecedented quantity and quality, planetary science has achieved a new perspective in the way we view our own planet. From the complex atmospheric chemistry of Venus to the evidence for climatic change on Mars, from the sulfur volcanoes of Io to the spiral density waves propagating through the rings of Saturn, from the superheated plasma of the Jovian magnetosphere to the isotopic imprint of supernova nucleosynthesis in the Allende meteorite, planetary perspectives now pervade our approach to a wide variety of problems in physics, astronomy, and the geosciences.

The fundamental goals of scientific exploration of the solar system have been (i) to determine the present state, origin, and evolution of the solar system, (ii) to better understand the Earth by comparative studies, and (iii) to improve our understanding of the relation between the appearance of life and the chemical history of the solar system. In the case of the moon, the Ranger, Sur-

veyor, and Lunar Orbiter missions also provided critical support to the manned Apollo Program, and in the future the need to assess resources for utilization by an increasing human presence in space may become an important supporting objective of planetary exploration (*7*).

To translate these general goals into a plan of action, we may consider a matrix. Along one dimension lie the diverse objects within the solar system: (i) the inner or terrestrial planets; (ii) the outer or Jovian planets, with their rings and satellite systems; and (iii) the comets and asteroids, chemically primitive debris surviving from the origin of the solar system. The second coordinate of the matrix is a measure of our level of knowledge. This knowledge has progressed, through a series of missions of increasing technological sophistication, from flyby reconnaissance spacecraft to orbiters, entry probes or landers, and ultimately return of samples for terrestrial analysis. Our progress in filling in this matrix has been uneven. We have been most successful in the inner solar system, reaching the level of landers on Venus and Mars and of sample return from the moon. In the outer solar system, we have accomplished flybys of Jupiter and Saturn, and in 1988 Galileo will provide an orbiter and entry probe for Jupiter. No missions have yet been launched to the small, primitive bodies, although several non-U.S. flyby missions are planned for Comet Halley when it approaches the sun three years from now (*3*).

Excluding the special case of the moon, the United States has launched 17 successful planetary spacecraft, including two Viking Mars landers and a group of Pioneer Venus atmospheric entry probes (Table 1). The U.S.S.R. has achieved success with 11 Venera missions to Venus, including seven landers. These missions have demonstrated our ability to apply the most advanced technology to important and challenging tasks outside the national security arena. But the pictures returned by a Viking or Voyager can also distort our perspective, because our approach to planetary exploration is the reverse of that used over centuries in the exploration of Earth. From space, we begin with a global view of another planet and only later move to detailed observations and measurements in selected regions. This has proved to be a powerful approach, but only because scientists have been able to extrapolate from their knowledge of basic processes learned on Earth. It generates an immediate global perspective, even from a first mission, but also tends to create an overly optimistic impression of the state of our knowledge. Experience has shown that many interpretations based on data from first-generation reconnaissance missions require substantial revision when more capable spacecraft arrive later (*8*). The importance of following up on our early discoveries cannot be overemphasized if we desire a true understanding of other planets and the processes that mold them.

A critical appraisal of where we stand today in planetary science also reveals large parts of the solar system where we have not even begun to explore. The entire surface of Venus and half that of Mercury remain terra incognita (*9*). No spacecraft has yet visited Uranus, Neptune, or Pluto (*10*), and we have only flyby data on Jupiter, Saturn, and their ring and satellite systems. We have yet to send a spacecraft to a comet or asteroid. These small, volatile-rich messengers from the distant past have not experienced the large-scale chemical and physical modification that has affected the larger planets and satellites, and they promise especially rewarding insights into the earliest history of the solar system.

Table 1. NASA planetary missions (not including lunar flights).

Spacecraft	Launch date	Destination	Encounter date	Type of encounter
Mariner 2	26 August 1962	Venus	14 December 1962	Flyby
Mariner 4	28 November 1964	Mars	14 July 1965	Flyby
Mariner 5	14 June 1967	Venus	19 October 1967	Flyby
Mariner 6	25 February 1969	Mars	31 July 1969	Flyby
Mariner 7	27 March 1969	Mars	5 August 1969	Flyby
Mariner 9	30 May 1971	Mars	13 November 1971	Orbiter
Pioneer 10	3 March 1972	Jupiter	4 December 1973	Flyby
Pioneer 11	6 April 1973	Jupiter	3 December 1974	Flyby
		Saturn	1 September 1979	Flyby
Mariner 10	3 November 1973	Venus	5 February 1974	Flyby
		Mercury	29 March 1974	Flyby
Viking 1	20 August 1975	Mars	19 June 1976	Orbiter
			20 July 1976	Lander
Viking 2	9 September 1975	Mars	7 July 1976	Orbiter
			3 September 1976	Lander
Voyager 1	5 September 1977	Jupiter	5 March 1979	Flyby
		Saturn	12 November 1980	Flyby
Voyager 2	20 August 1977	Jupiter	9 July 1979	Flyby
		Saturn	25 August 1981	Flyby
		Uranus?	1986	Flyby
		Neptune?	1989	Flyby
Pioneer Venus	20 May 1978	Venus	4 December 1978	Orbiter

Recommendations by the Space Science Board

In formulating a mission strategy, the SSEC has depended on scientific priorities for space science articulated by the National Academy of Sciences through its Space Science Board. Created in 1958, the Space Science Board has advised NASA throughout its history on overall scientific priorities (*11*). During the past several years, specific recommendations in planetary science have been developed by the Board's Committee on Planetary and Lunar Exploration (COMPLEX) and published in three reports (*12*). These reports are viewed as being of equal priority in shaping the scientific basis for the planetary exploration program.

For the inner planets, COMPLEX recommended a major focus on studies of the triad Venus, Earth, and Mars. These terrestrial planets, which are roughly similar in size, location, and composition, have followed strikingly different evolutionary tracks, and comparative studies should lead to a profound advance in knowledge, particularly with respect to our own planet. COMPLEX emphasized the gap in our knowledge represented by the unknown surface of Venus, and it accorded highest priority to the acquisition of a surface map with a resolution of ~ 1 kilometer.

The comets and asteroids represent the major planetary area in which spacecraft studies have not yet been initiated, and COMPLEX emphasized the urgency of beginning their study in order to probe the earliest periods of solar system history. Exploratory missions should sam-

ple the diversity of both comets and asteroids, as well as measure a few objects in detail.

Outer solar system studies are the one area of the planetary program that has retained a fair degree of momentum, with the forthcoming Voyager 2 flybys of Uranus and Neptune and development of the Galileo mission for a 1986 launch to Jupiter. For the next step, COMPLEX endorsed in-depth study of the Saturn system from an orbiter and a follow-up to the Voyager discoveries for Saturn's cloud-shrouded satellite Titan.

While COMPLEX and the Space Science Board have established the scientific objectives for future planetary exploration, they have not addressed the specific means by which these objectives should be accomplished. The development of a mission plan, with appropriate attention to technological and fiscal constraints, is the task of the SSEC.

Technological Considerations

Choice of missions has always depended in part on technological capability, and improvements in technology have led to more ambitious missions of increasing complexity, such as Viking, Voyager, and Galileo. In a period of budgetary constraint, it could be argued that the planetary community was pricing itself out of the market (*13*). Further, a cycle was developing in which the long intervals between flights decreased the opportunities for cost-saving use of hardware and designs from previous missions ("inheritance"), while increasing the pressure to include the maximum science payload in each flight. One of the first priorities of the SSEC was to break this cycle, increasing the opportunities for new missions by reducing their individual costs and phasing them together more efficiently (Fig. 1).

A first step was to identify the key elements that drive mission costs. There are three primary factors: (i) the degree of hardware and software design inheritance from mission to mission, (ii) the scientific scope and hence complexity of any given mission, and (iii) the degree of change that occurs after the mission is approved. The first two of these factors appear to be reinforcing, as noted above. The SSEC decided to limit its recommendations for a core program to missions that are restrained and focused in scope and where high inheritance can be achieved (*14*).

The missions in the core program must be insulated as far as possible from costly changes and delays once they are approved. In the past, many such changes have been outside the control of planetary program management, as in the delays and redirection in Galileo that arose from repeated launch vehicle changes. To avoid such costly problems, the SSEC has restricted its recommendations to missions that do not require new enabling technologies, such as specially designed upper stages, low-thrust propulsion systems, mobile landers, or sample return capabilities. Instead, it recommends vigorous utilization of the basic mission types that have been successful in the past: flybys, orbiters, and atmospheric entry probes. Such an approach promises a maximum scientific return on investment and a minimum probability of costly and disruptive delays.

Essential to the realization of the mission plan is the availability of the high-performance Centaur upper stage for the Shuttle. The Shuttle/Centaur brings within reach a number of missions, including comet and asteroid rendezvous, that were once thought to require such new technologies as low-thrust propulsion. Many missions in the core program require Shuttle/Centaur, but none demand more performance than will be provided by this combination (*15*).

Additional savings can be achieved in spacecraft design. For the inner solar system, the SSEC recommends the modification of spacecraft developed by aerospace companies for a variety of commercial applications in Earth orbit (*16*). Although there are few true production lines for spacecraft, the production rates within this industry are such that the costs of high-capability spacecraft are modest compared with those of the specialized spacecraft generally used for planetary exploration. Such spacecraft are limited to the inner solar system, however, since their thermal control, power, and communications systems would generally prove inadequate for more distant operations.

For exploration of the small bodies and the outer planets, the most efficient approach is to develop a modular spacecraft free of unnecessary complexity and designed for maximum inheritance and ease of reconfigurability. If the mass of this spacecraft (excluding fuel) can be held below 600 kilograms, a number of missions are possible that cannot be achieved with the larger Galileo-class vehicles. This new spacecraft, which would be similar in power, guidance, pointing, and communications capabilities to the Mariners and Voyagers, has been informally termed the Mariner Mark II. Its design, including the development of an integrated ground support system, is under way at Jet Propulsion Laboratory (*17*).

Additional efficiency for probe missions to the outer planets can be achieved by taking advantage of the highly capable Galileo entry probe. The Jovian entry problem will be the most demanding one; having solved it, we can use the same probe design for Saturn, Uranus, Neptune, and Titan. For these missions, the Mariner Mark II could serve as a probe carrier.

The use of derivatives of commercial Earth satellites for inner planet missions and of the Mariner Mark II for missions beyond Mars should lead to significant savings in both mission development and operations. Efficiency will be increased in both cases if the science objectives for each mission are carefully controlled and the frequency of launches is high. These approaches provide the key to carrying out planetary exploration within a constrained budget.

Proposed Missions for the Core Program

Consistent with its conviction that our understanding of the solar system is best served by a balanced exploration program, the committee recommends missions in all three major areas: inner planets, small bodies, and outer planets. For the core program discussed here, only modestly priced missions that do not require new enabling technology are proposed (see Table 2).

Inner planets. A principal scientific objective of inner solar system exploration is to understand the nature and evolution of the interiors, surfaces, and atmospheres of Earth, Venus, and Mars. It has been apparent for some time that the single largest gap in our data base for these planets is our ignorance of the geology of Venus. While the Pioneer Venus Orbiter was able to produce a global altimetry map with a maximum horizontal resolution of 50 to 75 km (*18*), there is virtually no information on the surface topography on scales that might reveal most geological processes and history. The SSEC assigns its highest mission priority to a Venus Radar Mapper (VRM), which will provide a global reconnaissance of the surface equivalent to that carried out by cameras on the first Mars orbiter, Mariner 9 (*19*). The objectives of this mission are to (i) obtain a near-global map by using synthetic aperture radar with subkilometer resolution, (ii) provide global and local topographic

Table 2. Missions in the SSEC core program. These are not listed in order of priority, except as noted in the text.

Inner planets	Small bodies	Outer planets
Venus Radar Mapper	Comet Rendezvous	Titan Probe/Radar Mapper
Mars Geoscience/Climatology Orbiter	Comet Atomized Sample Return	Saturn Orbiter
Mars Aeronomy Orbiter	Main Belt Multiasteroid Orbiter/Flyby	Saturn Probe
Mars Surface Probe	Near-Earth Asteroid Rendezvous	Uranus Probe
Lunar Geoscience Orbiter		
Venus Atmospheric Probe		

information with a radar altimeter, and (iii) extend the global gravity field measurements obtained by Pioneer Venus. This mission is proposed for launch in 1988 and will complete its primary phase after 243 days in Venus orbit (*20*).

The VRM mission has been derived from studies of a more complicated, twice as expensive mission, the Venus Orbiting Imaging Radar (VOIR) (*21*). As presently conceived, it capitalizes on a number of the cost-saving measures, including (i) limited science objectives (focused on radar mapping, to the exclusion of various atmospheric studies planned for VOIR), (ii) high hardware inheritance (for instance, use of a spare Voyager antenna for both the radar mapper and Earth communications), and (iii) use of new technology to reduce costs (advances in synthetic aperture radar allow imaging from an elliptical orbit, providing major cost and weight savings relative to the low circular orbit planned for VOIR).

The highest priority scientific objectives for Mars require the return of a surface sample to Earth and therefore lie outside the boundaries of the core program. However, many objectives that are basic to understanding Mars are attainable within the SSEC guidelines. These include studies of surface composition and mineralogy, of the distribution and atmospheric transport of volatiles, of global atmospheric dynamics, and of the structure and photochemistry of the upper atmosphere. All these investigations, which would produce major advances over the limited measurements made by the two Viking orbiters, can be carried out with relatively simple spacecraft derived from commercial Earth satellites.

The SSEC recommends early initiation of a Mars orbiter, emphasizing investigation of the geology and climate of the planet. The Mars Geoscience/Climatology Orbiter, the first of the new class of low-cost inner planet missions, should be launched in 1990 into a 300-km polar orbit, where it would operate for one Mars year. Its objectives are to obtain global maps of elemental and mineralogical surface composition and of the planet's figure and surface topography, to deduce the nature of the magnetic field (if any), to measure the seasonal cycles of carbon dioxide, water, and dust, and to study the interactions between volatile reservoirs (such as the polar caps) and the atmosphere. High-resolution imaging is not a part of this mission. The Viking orbiters have already given us excellent maps of Mars, and our greatest scientific need now is for quantitative data of the type discussed for this mission.

If humans are to consider the establishment of a permanent and self-sufficient presence in space, we must learn more about our nearest neighbors, the moon and the near-Earth asteroids. The same spacecraft and instruments used to map the figure, surface topography, and composition of Mars can also be used to carry out similar studies of the moon from polar orbit (*22*). The SSEC recommends that a Lunar Geoscience Orbiter be included as a follow-up to the Mars orbiter to realize the maximum savings from hardware inheritance and joint mission operations. A similar early opportunity exists to send a geochemical spacecraft, supplemented by imaging cameras, to rendezvous with an Earth-approaching asteroid and initiate our exploration of this new class of objects (*23*).

Other inner planet missions in the SSEC core program are a Venus Atmospheric Probe, a Mars Aeronomy Orbiter, and Mars hard landers or penetrators. These are all missions to be initiated in the 1990's, and it is hoped that one or more of them might be carried out by other nations, either independently or in collaboration with NASA.

Small bodies. Comets and asteroids compensate for their diminutive size by their large numbers and by the extraordinary interest they hold as chemically primitive objects, little modified since their presumed formation 4.6×10^9 years ago. The diverse populations of comets and asteroids have been much studied by telescope in recent years (*24*), but no mission has been launched to any of these objects, in spite of studies and recommendations that go back to the early days of NASA (*25*). To maintain a balanced perspective on the planetary system and particularly to probe the conditions of its birth and early evolution, the SSEC concurs with COMPLEX and other advisory bodies in recommending early initiation of missions to comets and asteroids.

An essential element of comets and asteroids is their diversity. No one object holds the key to either class. However, there is sufficient information about the characteristics of the major classes of comets and asteroids to permit an intelligent selection of targets, while the Shuttle/Centaur has the capability to launch spacecraft that can visit more than one target in a single mission. Thus we are technologically and scientifically poised to begin the direct exploration of these smaller worlds.

Following the fast flybys of Comet Halley in 1986, the next step in cometary exploration should be a rendezvous mission with a short-period comet. The spacecraft would match orbit with its target many weeks before perihelion and follow it through its activity cycle as it is heated by sunlight and then recedes again into deep space. Among the accessible short-period comets, three suitable targets have been identified: Encke, Tempel 2, and Honda-Mrkos-Pajdusakova (HMP). Each has a period of less than ten years, and each has suitable apparitions during the late 1980's and the 1990's (*26*). The spacecraft would carry cameras and other remote sensing instruments (similar to those on Voyager or Galileo) in addition to direct sensing instruments to study the gas and dust in the cometary atmosphere. Comet HMP presents one of the first opportunities for a rendezvous, with a 1990 launch, 1994 arrival, and 1995 perihelion. En route to its primary target, the spacecraft would fly by a main-belt asteroid, initiating a study of this class of objects. A comet rendezvous is the first Mariner Mark II mission in the core program.

Complementing a rendezvous is the acquisition and return to Earth of a sample of cometary material. It is usually assumed that sample returns can be attempted only after a sequence of reconnaissance and exploration missions. For comets, however, a novel kind of sample return can be carried out even within the restrictions of the SSEC core program. A simple fast-flyby spacecraft can acquire an atomized sample return of dust particles that are vaporized by impact on a foil diaphragm and recondense on the walls of a collection cell, which is returned to Earth for laboratory analysis.

38-036 O - 84 - 64

In this way, a detailed analysis of the elemental and isotopic composition of the nonvolatile component of cometary dust can be carried out. For Comet HMP, a 1994 launch would yield an encounter in 1995 and a return to Earth in 1996 (*27*).

For initial exploration of the asteroids, the SSEC recommends a Main Belt Multiasteroid Orbiter/Flyby Mission. A combination of flybys and orbiters is required to achieve the necessary depth and breadth, but these functions can be combined in a single Mariner Mark II spacecraft with Shuttle/Centaur launch (*28*). The objectives are Voyager-class imaging and remote sensing studies of several asteroids en route to (or following) a 60- to 90-day orbit of the primary target. During orbit, more detailed elemental and mineralogical analysis of the asteroid surface can be carried out. One mission studied for a 1992 launch would have as its primary target asteroid 4 Vesta, one of the largest and most interesting main-belt objects (*29*), with additional flybys of 313 Chaldaea and 101 Helena, two objects of differing compositional type with diameters of 120 and 70 km. In general, opportunities for good main-belt asteroid missions recur at two-year intervals throughout the 1990's.

Outer planets. In the giant outer planets and their systems of rings and satellites are found more than 99 percent of the planetary system's mass, 45 of the 48 known satellites, the only ring systems, and (in the case of Jupiter and Saturn) magnetospheres that are vastly larger and more complex than those associated with the inner planets. During the rest of this decade, Voyager 2 will continue its mission to Uranus and Neptune, while Galileo will provide a much more detailed investigation of the Jupiter system. The next step, beyond Voyager and Galileo, will be the in-depth exploration of the Saturn system, especially its largest satellite, Titan.

The SSEC's first priority mission to the outer solar system is a Titan Probe/Radar Mapper, ideally to be carried out in conjunction with a Saturn Orbiter. Titan is unique, having an evolved reducing atmosphere that contains more nitrogen than our own, in addition to methane, carbon monoxide, and more complex organic compounds. The surface of Titan is cold enough for methane to condense, possibly forming pools or oceans. A Titan probe could be a modification of the Galileo Jupiter probe, with an instrumented package to sound and sample the atmosphere as it descends by parachute to the surface. At the same time, radar on the probe carrier could provide an image of part of the cloud-shrouded surface at a resolution of a few kilometers.

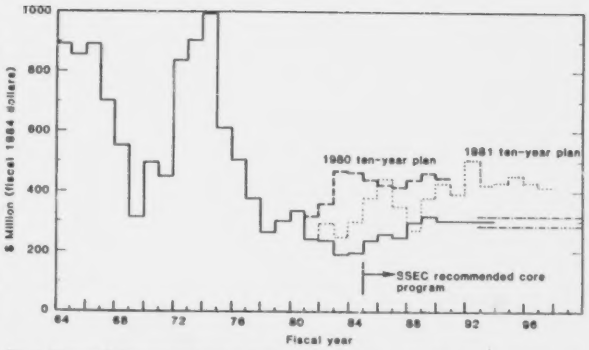

Fig. 1. History of planetary exploration funding: annual budgets of NASA's Planetary Division since FY 1964, expressed in constant value (FY 1984) dollars. Three future projections are shown: the NASA ten-year plan of 1980, the NASA ten-year plan of 1981, and the SSEC core program of 1983. Note that the annual expenditures in the SSEC core program are one-third the high levels of funding of the middle 1960's and 1970's.

If the Titan probe carrier is a full-scale Saturn Orbiter, a mission analogous to Galileo could be carried out in the Saturn system, with detailed study of the atmosphere, magnetosphere, satellites, and rings. Launches can be accomplished every 13 months, with a flight time of six to eight years (*30*). A combined Titan Probe and Saturn Orbiter has been considered an excellent candidate for international cooperation.

The other outer planet missions in the SSEC core program are atmospheric probes based on the Galileo probe design. The objective of these missions is the direct comparative study of the atmospheres of Saturn, Uranus, and Neptune with instruments similar to those being sent to Jupiter. The probe carriers could be instrumented for flyby remote sensing more advanced than that of Voyager; such a capability would also provide a backup in case Voyager 2 fails before it completes the initial reconnaissance of the outer two giant planets (*31*).

Mission summary. The recommended core program includes 14 missions, to be launched between 1988 and 2000. The first four missions in this sequence have been analyzed in some detail and can be firmly recommended at this time. These are (i) the Venus Radar Mapper (1988 launch), (ii) the Mars Geoscience/Climatology Orbiter (1990 launch), (iii) the Comet Rendezvous with Asteroid Flyby (1990 launch), and (iv) the Titan Probe/Radar Mapper. The Titan mission would probably be launched in the early 1990's, but international cooperation could result in an earlier mission, perhaps in conjunction with a Saturn Orbiter.

The sequence of other missions in the core program will be determined by programmatic issues that cannot be foreseen at this time. Major considerations in their execution should include the need to maintain scientific balance and the desire to realize maximum efficiencies in cost and utilization of manpower. These additional missions are, in no order of priority: Mars Aeronomy Orbiter, Venus Atmospheric Probe, Lunar Geoscience Orbiter, Mars Surface Probe, Near-Earth Asteroid Rendezvous, Main-Belt Multiasteroid Orbiter/Flyby, Comet Atomized Sample Return, Saturn Probe, Uranus Probe, and Saturn Orbiter. The SSEC recommends that all of these moderate-cost missions be undertaken between now and the year 2000, by the United States alone or in collaboration with other nations (*32*).

Costs of the Core Missions

In developing the core mission program, the SSEC considered it unrealistic to anticipate a return to planetary budgets of $500 million or more a year. On the other hand, it recognized that if the launch rate of planetary missions becomes too low, then economies resulting from inheritance and common operation systems will evaporate.

The missions in the core program that follow the Venus Radar Mapper fall very roughly into two cost categories: the inner planet missions based on derivatives of Earth-orbital spacecraft, which are estimated to cost on the order of $100

million to $150 million, and the Mariner Mark II missions, which approach $250 million to $300 million in recurring costs (*33*). To sustain momentum in either program a launch about every two years is required. This is also the launch rate required to carry out most of the recommended core missions between 1988 and 2000. We therefore estimate an annual cost for flight programs, exclusive of mission operations or data analysis, of about $150 million to $200 million.

Two other essential elements of the planetary budget, in addition to flight missions, are funds for basic research (including analysis of data from past missions and planning for future flights) and for mission operations. The minimum for data analysis and research is about $100 million per year, while mission operations can, with implementation of a common operating system and use of new technology to reduce costs, be held to about half this value. Both of these items must be added to the cost of flight missions in establishing the base cost of planetary exploration.

The SSEC core program requires a sustained annual funding level of $300 million to $350 million in current (FY 1984) dollars. This level, which is about one-third of the high level of a decade ago, is sufficient to support a vigorous program of individually modest missions, and it promises to return a great deal of high-quality scientific data in a cost-effective manner.

Management Implications

The proposed core mission program represents a new approach to NASA's planetary program, and its success will depend on certain modifications of current practice. Primarily these reflect the interrelations among the proposed missions. Much of the efficiency of the approach can be realized only if the individual missions are closely spaced and planned to make maximum use of human and material resources, including the unique capabilities of the NASA centers. If treated as episodic, isolated events, these missions are unlikely to be accomplished in a cost-effective manner. Therefore, the recommended SSEC core program assumes a long-term commitment to planetary exploration with reasonably constant funding levels.

For these goals to be accomplished, the core program should be judged in terms of overall effectiveness and managed for maximum return from the entire program, not from each mission individually. The SSEC strongly urges that the inner planet missions in particular be treated as a continuing series, modeled after the highly successful Explorer program in the NASA Astrophysics Division (*34*). We endorse the concept of a similar Planetary Observer effort, funded as a level-of-effort program at about $60 million per year (in FY 1984 dollars), out of which the proposed inner planet missions would be supported. (These funds include about $10 million per year to be used for support of U.S. investigators on international planetary missions.) We urge that a similar management approach be taken for the Mariner Mark II missions, although we recognize that the magnitude of these missions makes it likely that each will require scrutiny as an individual "new start" when full-scale development begins (*35*). We recommend the rapid development of a common mission operations system in the planetary area, to be used for both Observer and Mariner Mark II missions.

Missions Beyond the Core Program

Many important scientific goals are excluded from the core program on the basis of cost and technological challenge. These include the return of samples from Mars, the exploration of the martian surface with mobile landers, the return to Earth of pristine fragments from a comet, and the operation of a buoyant station in the atmosphere of Titan. Such missions would provide scientific data fundamental for understanding the origin and evolution of the solar system, and they could generate the kind of public enthusiasm and international acclaim associated with Apollo, Viking, and Voyager. In addition, meeting such challenges would contribute to the strength of high technology in the United States. Challenging larger missions should be accepted (*36*). However, our first priority is to restore and maintain the health of planetary exploration in this nation, and we believe the core program approach advocated by the SSEC contributes to this goal.

References and Notes

2. The NASA planetary budget reached record lows of $210.0 million in fiscal year (FY) 1982 and $186.4 million in FY 1983. For comparison, the funds appropriated in peak years FY 1973 and FY 1974 (when the Viking and Voyager missions were under full-scale development) were each over $900 million in FY 1984 dollars.
3. The last opportunity for a U.S. mission to Halley passed in FY 1982. However, fast-flyby spacecraft are being sent to the comet by the U.S.S.R. (Vega), the European Space Agency (Giotto), and Japan (Planet B).
4. The membership in the SSEC is: A. Albee, Caltech–Jet Propulsion Laboratory (JPL); K. Anderson, University of California, Berkeley; J. Arnold, University of California, San Diego; C. Barth, University of Colorado; G. Briggs, NASA headquarters; T. Donahue, University of Michigan; M. Duke, NASA/Johnson Space Flight Center; L. Fisk, University of New Hampshire; L. Haskin, Washington University; N. Hinners, NASA/Goddard Space Flight Center; D. Hunten, University of Arizona; H. Klein, NASA/Ames Research Center; E. Levy, University of Arizona; J. Martin, Martin Marietta Corp.; H. Masursky, U.S. Geological Survey; D. Morrison, University of Hawaii; J. Naugle, Fairchild Space and Electronics Corp.; J. Niehoff, Science Applications, Inc.; T. Owen, State University of New York Stony Brook; D. Rea, Caltech–JPL; L. Soderblom, U.S. Geological Survey; E. Stone, Caltech; J. Veverka, Cornell University; and L. Wilkening, University of Arizona. An additional 40 planetary scientists participated in the preparation of the SSEC report through service in five topical working groups or through supporting studies carried out at NASA centers.
5. A detailed report on the SSEC core program [*Planetary Exploration Through Year 2000: A Core Mission Program* (NASA, Washington, D.C., in press)] should be available by 1 June.
6. The number of workers in this field is estimated from such data as the 1983 membership in the Division for Planetary Science of the American Astronomical Society (450), 1981 membership in the Planetology Division of the American Geophysical Union (694), attendance at the 1982 NASA Lunar and Planetary Science Conference (557), and number of principal investigators in the NASA planetary research grants programs (422).
7. As a result of its assessment of the rationale for planetary exploration, the SSEC recommends the addition of the following fourth objective: "to provide a scientific basis for the future utilization of resources available in near-Earth space." The committee rejected recommending a narrower overall focus for the program, such as concentration on missions leading to manned exploration of Mars, since it believes the primary aim should continue to be broad scientific exploration of the planetary system.
8. For example, data on the concentrations of isotopes of the noble gases in the atmospheres of Venus, Earth, and Mars, which are critical for understanding the origin and early evolution of the terrestrial planets, were not obtained until 1976 for Mars and 1979 for Venus—11 and 17 years, respectively, after initial flybys of these planets. See, for example, T. Donahue and J. B. Pollack, in *Venus*, D. M. Hunten and L. Colin, Eds. (Univ. of Arizona Press, Tucson, 1983), pp. 1003–1031; L. M. Mukkin, in *ibid.*, pp. 1037–1045.
9. Mariner 10 photographed half the surface of Mercury during its flybys in 1973 and 1974. The surface of Venus, hidden beneath thick clouds, has been probed by ground-based and Pioneer Venus radar, but their best resolution of ~ 50 km is insufficient to reveal any but the grossest topographic features.
10. Voyager 2 is on a trajectory that will yield a flyby of Uranus in 1986 and of Neptune in 1989; the spacecraft was not designed for operation beyond the 1981 Saturn encounter, so the anticipated results from the Uranus and Neptune flybys remain uncertain.

13. In fact, costs of planetary missions in recent years have increased only modestly relative to inflation. Much of the high cost for Galileo has resulted from repeated delays and reconfigurations imposed by the Shuttle and its upper stages; in their absence, Galileo would have cost less than Voyager. However, it is clear that the absolute cost of missions is of great concern, and there has been little emphasis on applying new technology to reduce cost rather than enhance spacecraft capabilities.
14. Inevitably, this constraint eliminates from the core program a number of missions that address high-priority science goals identified by the Space Science Board. Examples are Mars sample return missions and the exploration of the martian surface by mobile laboratories.

15. Modification of the Centaur to carry out planetary missions with the Shuttle is under way, with the first launches scheduled for Galileo and the International Solar Polar Mission in 1986. Many missions in the core program could also be carried out with the solid-fuel Inertial Upper Stage, but with less margin and consequently greater risk of unanticipated costs.
16. Examples of such spacecraft with a potential planetary application are the Hughes Aircraft Co. HS-376, the TRW (Navy) Fleet Communications Satellite (FLTSATCOM), and the RCA Defense Meteorological Satellite Program (DMSP). The SSEC believes that appropriate derivatives of these spacecraft could be acquired for under $90 million (in FY 1984 dollars, and exclusive of scientific instruments and mission operations costs).

18. H. Masursky *et al.*, *J. Geophys. Res.* **85**, 8232 (1980); G. E. McGill *et al.*, in *Venus*, D. Hunten and L. Colin, Eds. (Univ. of Arizona Press, Tucson, 1983), pp. 69–130.
19. Mariner 9 discovered the giant volcanoes, ancient water channels, aeolian deposits, layered polar caps, and other terrain types that reveal the varied climatic and geological history of Mars. Subsequent Viking orbiter photography increased the imaging resolution for much of the planet to ~ 100 m.
20. Development funds of $29 million are included in the Administration's FY 1984 budget request. If approved, VRM will be the first planetary new start since Galileo in FY 1978.
21. The VOIR mission was proposed as an FY 1982 new start in the Carter Administration budget but was dropped from the revised FY 1982 budget of the Reagan Administration.
22. Geochemical mapping of the moon by x-ray and gamma-ray spectrometry was carried out from lunar orbit during the Apollo program but never extended beyond the equatorial regions. Improved instruments in polar orbit would generate the global perspective needed for proper interpretation of the Apollo lunar samples and could also search for postulated reservoirs of frozen water in permanently shaded regions near the poles.
23. The Earth-approachers are small asteroids in relatively unstable orbits (lifetimes ~ 10^6 years) that approach or intersect that of Earth. They may be derived from the main asteroid belt or they may represent extinct comet nuclei, or probably both. Their small sizes, unstable orbits, and unknown provenance argue for consideration separate from the larger asteroids in stable orbits between Mars and Jupiter.
24. T. Gehrels, Ed., *Asteroids* (Univ. of Arizona Press, Tucson, 1979); L. Wilkening, Ed., *Comets* (Univ. of Arizona Press, Tucson, 1982).
25. D. L. Roberts, Ed., *Proceedings of the Cometary Science Working Group—Yerkes Observatory (June 1971)* (ITT Research Institute, Chicago, 1971); M. Neugebauer *et al.*, Eds., "Space missions to comets," *NASA CP-2089* (1977); M. Belton, Ed., "A first comet mission," *NASA Tech. Memo. TM-78420* (1977).
26. Encke is the most difficult of the three comets from an engineering point of view because its orbit takes it closer to the sun than Mercury. Tempel 2 has suitable apparitions in 1993 and 1999, and HMP in 1995. Other possible targets include Kopff (1996) and Wild 2 (1997).
27. Atomized (or plasmatized) sample return was first proposed for Comet Halley in 1981. Laboratory simulations suggest that major elemental and isotopic abundances can be measured with sufficient precision to distinguish among major meteorite types and even to yield an Rb-Sr model age.
28. A number of attractive missions would use a Mars-powered flyby for extra propulsive capability [C.-W. Yen, *AIAA Paper 82-1463* (1982)]. These are primarily combinations of a single orbit target with multiple flybys, but in a few cases the spacecraft could orbit two different main-belt asteroids. If a low-thurst ion propulsion system were available, many more such multiorbiter missions would be possible.
29. Vesta, with a diameter of 550 km, has a unique basaltic surface indicative of a complex and dynamic thermal history. Many meteoriticists consider it the parent body of the eucrite group of meteorites [see M. J. Drake, in *Asteroids*, T. Gehrels, Ed. (Univ. of Arizona Press, Tucson, 1979), pp. 765–782].
30. To reach Saturn, a Shuttle/Centaur-launched orbiter spacecraft requires a so-called delta-Vega trajectory with gravity assist from an Earth flyby about a year after launch. In contrast, with a direct flyby trajectory it would take only 3.5 years to reach Saturn.
31. Ideal times to launch spacecraft recur at roughly 13-year intervals, when Jupiter is in position to provide a gravity assist. Voyager took advantage of this planetary alignment in 1977. The next opportunity will be in 1992—unfortunately, too early in the sequence of core missions to be utilized. Uranus can still be reached during the 1990's without a Jupiter boost, but we have had to drop Neptune from the targets in the core program.
32. We anticipate that some of the missions in the core program will be carried out by other nations, perhaps jointly with NASA. For example, of the missions under consideration by the ESA, Kepler is similar to our Mars Aeronomy Orbiter and Aqora to our Main Belt Asteroid Multiple Orbiter/Flyby, while the U.S.S.R. Venera program could accomplish the objectives of the Venus Atmospheric Probe.
33. Following usual NASA practice, estimated costs, in FY 1984 dollars, exclude the cost of launch vehicles and of the Deep Space Tracking Network. Mission operations and data analysis are also budgeted separately.
34. NASA's Explorers have recently been supported at a level of about $35 million per year, and it is proposed that this be increased to $50 million beginning in FY 1984. Recent examples of Explorers are the UHURU X-ray Observatory, the International Ultraviolet Observatory (IUE), the Dynamic Explorers (DE's), the Solar Mesosphere Explorer (SME), and the Infrared Astronomy Satellite (IRAS).
35. A similar argument for continuity of funding throughout the space science program has recently been made by the Congressional Office of Technology Assessment ("Space science research in the United States," OTA Technical Memorandum, September 1982).
36. During 1983, the SSEC is undertaking a study of larger missions that might be included in an augmented planetary program.
37. The activities of the SSEC are supported by the NASA Advisory Council and the Earth and Planetary Exploration Division of NASA headquarters. We thank the members of the SSEC and its working groups, the supporting staffs at Jet Propulsion Laboratory and Ames Research Center, and especially G. Briggs, executive director of the SSEC, for their invaluable contributions to this effort.

military affairs abroad

MILITARY IMPLICATIONS OF INDIA'S SPACE PROGRAM

FIRST LIEUTENANT JERROLD F. ELKIN
CAPTAIN BRIAN FREDERICKS, USA

IN A COUNTRY where the bullock cart still constitutes a principal mode of transportation, India's space program stands out as a dramatic achievement. Although New Delhi has consistently maintained that the space program bears no relation to defense requirements, India could produce an intermediate-range ballistic missile (IRBM) by the end of the decade assuming requisite political determinations are made. This article identifies the present accomplishments of India's space effort and discusses near- and mid-term program objectives. Further, it

examines potential military application of Indian space technology and analyzes those factors most likely to enter New Delhi's decision calculus respecting development of a nuclear weapon carrier missile system.

India's Space Achievements

On 18 July 1980, India successfully launched the Rohini I satellite and thereby became the sixth nation—after the Soviet Union, the United States, France, Japan, and China—to orbit a satellite with an indigenously produced launch vehicle. This event demonstrated that, in the eighteenth year of its existence, India's space program had become a truly sophisticated enterprise. In an organizational sense, the program began in 1962 with the creation of the Indian National Committee for Space Research under the Department of Atomic Energy. The formation of the Indian Space Research Organization (ISRO) in 1969 highlighted the transition of the space effort from a scientific undertaking of limited magnitude to a coordinated program with specific goals and time-bound projects in space applications and technology. The program's organizational structure was further augmented in 1972 with the establishment of a Space Commission and a Department of Space. The Space Commission is responsible for general policy formulation and approval of the budget of the Department of Space. The Department of Space is tasked with planning, programming, and resource allocation. The ISRO is a constituent element of the Department of Space.[1]

Professor Satish Dhawan, Chairman of the Space Commission and ISRO and Secretary to the Government in the Department of Space, has been the driving force behind India's space undertakings. Under Dhawan, India has made material progress in the areas of satellite and launcher development and ground support infrastructure expansion. While Dhawan has emphasized the need to enhance indigenous capability in all aspects of space technology, he has recognized that, as an interim step, acceptance of foreign assistance is imperative. Such assistance, in the form of satellite design support and actual launching of Indian satellites, has come from the United States, the U.S.S.R., and France.

On 19 April 1975, India's first satellite, the 35 kg Aryabhata, was placed in a 600 km circular orbit by a Soviet rocket. The launching of Aryabhata demonstrated the ability of Indian scientists to design and fabricate orbital satellites. With the exception of the solar panels and batteries, all of Aryabhata's systems were manufactured in India. Beyond this, the Indians evidenced an ability to employ receiving, transmitting, and tracking facilities for the purpose of satellite monitoring.

India's second experimental satellite, the 444 kg Bhaskara, was launched in June 1979 from the U.S.S.R. on a Soviet rocket. The Bhaskara carried two remote-sensing payloads: a television camera and microwave imaging system. However, the TV camera failed to operate for nearly a year. After an extensive simulation exercise, Indian scientists were able to remedy the problem, and in May 1980 the satellite began transmitting as many as ten pictures a day. The quality of the nearly 1000 pictures sent back by Bhaskara's TV camera compared favorably with similar pictures taken by other meteorological satellites.[2]

While the Aryabhata and Bhaskara were placed in orbit by Soviet boosters, Indian efforts to design and fabricate a satellite launch vehicle continued apace. An indigenously produced four-stage, solid fuel rocket, designated the SLV-3, made its maiden flight on 10 August 1979. A malfunction in the second stage caused a flight termination after only 317 seconds. However, in July 1980, the SLV-3 successfully injected the 35 kg Rohini I satellite into near-earth orbit. The primary objectives of the Rohini I were performance evaluation of the SLV-3 and determination of the satellite's orbital characteristics.[3] The magnitude of this achievement becomes apparent when one considers that Japan, a technologically advanced nation, was

unable to put a satellite into space until its fifth attempt.

The year 1981 witnessed an acceleration of India's space activity. In May, the second Rohini satellite, with an expected mission duration of 300 days, was placed into an elliptical orbit. The Rohini carried a landmark sensor of Indian manufacture capable of photographing areas 250 by 80 km with a resolution of 1 km. However, a problem in the fourth stage resulted in a failure to achieve required orbital altitude; in consequence, Rohini II reentered the earth's atmosphere after only nine days in space. In June, India's first geostationary satellite was launched by the European Space Agency from French Guiana. This satellite, known as APPLE (Ariane Passenger Payload Experiment), was meant to serve as a test bed for India's communication satellite program. The most critical phase of the APPLE mission profile involved employment of an apogee boost motor to shift the spacecraft from a transfer to a drift orbit, from which the satellite was maneuvered to its permanent station.[4] The success of Indian scientists in correctly positioning APPLE was trumpeted by the Indian press, which emphasized that this capability had been previously demonstrated only by the United States, the U.S.S.R., France, and Canada. In November 1981, Bhaskara II, India's second earth observation satellite, was launched from a Soviet cosmodrome. Unlike its predecessor, the Bhaskara II experienced no problems with its cameras. This satellite provided information, inter alia, on cloud formation and atmospheric moisture content.

India's communication capability will be further enhanced with the initiation of Indian National Satellite (INSAT) operations. In addition to telecommunications and direct TV broadcasting, the INSAT system will have a meteorological earth observation and data relay mission. Two INSAT spacecraft have been fabricated by a U.S. firm according to Indian specifications. INSAT's ground support equipment will include thirty-five tracking stations, six of these being mobile facilities.

INSAT-1A was launched from the Kennedy Space Center on 10 April 1982 and inserted into a geosynchronous orbit on the thirteenth. However, a premature exhaustion of thruster propellant resulted in a cessation of operations only 150 days after launch. Nevertheless, New Delhi remains satisfied with the basic design, and a 1983 launching of INSAT-1B is anticipated.

Projected Space Development Programs

The Indians have embarked on a number ot satellite development projects to be completed by the end of the decade. Among these is proto-INSAT, which will be used in establishing design parameters for indigenously built INSAT replacement satellites. However, it is in the area of booster technology that impressive advances can be anticipated in the near term. During the 1980s, India intends to produce an augmented satellite launch vehicle (ASLV) and a polar satellite launch vehicle (PSLV). The ASLV will consist of an SLV-3 with two first-stage SLV-3 rockets as strap-on boosters. The ASLV will be able to inject a 150 kg payload into low-earth orbit, as compared with the 35-50 kg lift capacity of the SLV-3. As presently configured, the PSLV will consist of a solid fuel booster with six strap-on motors derived from the SLV-3 first stage, a liquid fuel second stage, and two solid fuel upper stages. This launch vehicle, designed to place a 1000 kg payload into a 900 km polar sunsynchronous orbit, is expected to be operational by 1987.

Dr. Abdul Kalam, head of launch vehicle development in the ISRO, has declared that by 1990 India will be able to position a 2500 kg communication satellite into geosynchronous orbit at 36,000 km. He has further asserted that the ISRO can produce a cryogenic rocket engine (using liquid oxygen and liquid hydrogen) during the 1980s. The Indians consider cryogenic engines more cost effective than rockets employing solid or storable liquid fuel because of greater thrust generation and the possibility of reduced vehicle size.[5]

Military Implications of Space Research

The Indian leadership has emphasized that advances in rocket and satellite technology will not be translated into an enhanced military capability. Thus, for example, the Minister of State in the Ministry of Defense apprised Parliament after the launching of Rohini I that no plans existed for the manufacture of IRBMs.[6] Despite such pronouncements, potential military applications of Indian space technology are manifold, to include development of reconnaissance satellites, improvements in command and control, greater precision in operational planning based on satellite-derived meteorological data, and IRBM production.

reconnaissance satellites

India has already designed a satellite camera system and placed it into orbit. While the resolution of the Rohini II landmark sensor was inadequate for detailed surveillance activity, it would have allowed New Delhi to locate road and rail nets in neighboring countries. The 1981 acquisition of advanced MiG-25 Foxbat reconnaissance aircraft from the Soviet Union evidences India's interest in improving its ability to monitor military installations and troop movements in Pakistan and China. The production of satellites (employing sophisticated optics either indigenously fabricated or acquired from third countries) would appreciably augment India's existing photographic intelligence resources.

command and control

A substantial upgrading of India's domestic communication infrastructure constitutes a fundamental objective of the INSAT program. The INSAT-1B platform will have twelve communication channels, each able to handle 2000 telephone conversations, plus two direct broadcast television channels. The applicability of such an information transmission system to defense requirements is patent. Thus, for example, the six mobile down links associated with INSAT may well prove forerunners of systems integrated into army units that will enable these units to deploy from peacetime cantonments with little or no communication disruption. Similarly, satellites could increase the effectiveness of the Indian Navy both by ensuring continuous communication with all naval vessels and improving the accuracy of maritime navigation. In this context, it must be appreciated that India's armed forces comprise the world's fourth largest army, the fifth largest air force, and a navy transitioning from a coastal defense force to a blue-water fleet. A military organization of this magnitude, with installations distributed throughout India and numerous warships at sea, would derive particular benefit from a satellite-enhanced C^3 network.

weather forecasting

Weather conditions form a critical variable in military planning. The greater precision in weather forecasting afforded by Indian meteorological satellites will, in consequence, materially assist planners in structuring military exercises or actual combat operations.

intermediate-range ballistic missiles

The Indian political leadership has consistently asserted that the activities of the Department of Space are nonmilitary in nature. However, Satish Dhawan declared in 1979 that the SLV-3 could be converted into an IRBM with a range of approximately 1500 km.[7] Adoption of such a course of action would appear to have the support of India's armed forces. An editorial in the November 1981 edition of *Vikrant*, a semiofficial Indian military publication, states that India ". . . must possess adequate capability for strategic long-range strike in the form of MRBM/IRBMs equipped with nuclear warheads, a strategic air strike and interdictor force and adequate air defence, all equally complementary and coordinated."[8]

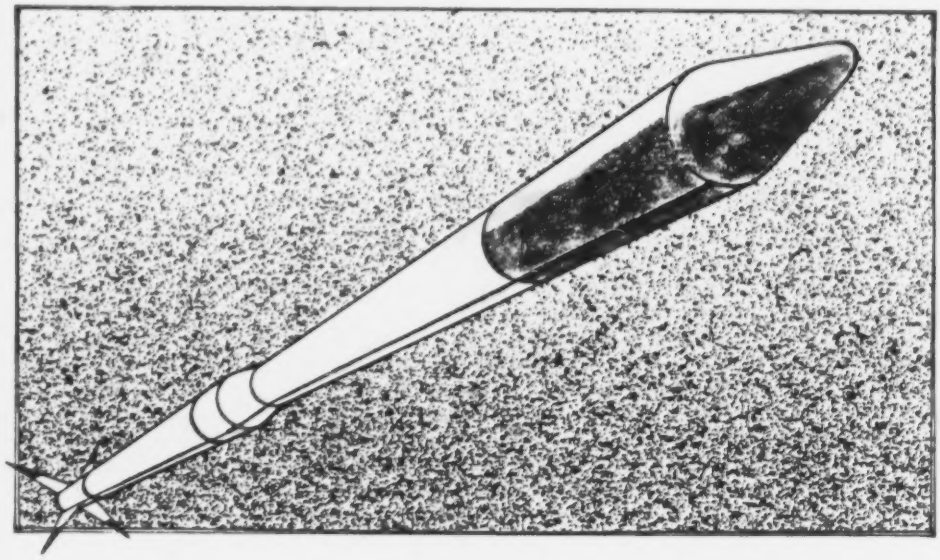
Modification of the SLV-3 into a nuclear-

weapon-carrier missile involves more than mere payload substitution; rather, a number of significant technological difficulties must be surmounted. First, a reentry heat shield capable of withstanding temperatures of several thousand degrees centrigrade must be developed. It has been reported that Indian scientists are presently endeavoring to perfect an ablative heat shield system that would satisfy this requirement.[9] Second, sophisticated guidance systems are needed to ensure that warheads arrive at their targets. India's demonstrated capability to maneuver a satellite into geosynchronous orbit evidences possession of sensitive position-correcting instruments. A senior Indian scientist has asserted that such guidance systems could be applied to defense purposes after modest refinement.[10]

Indian military affairs analyst R. R. Subramanian notes that the SLV-3, a four-stage launcher using solid propellant motors, is far from an ideal weapon delivery vehicle. The disadvantages of a four-stage rocket are said to include the need to integrate control and guidance equipment with each of the stages and the increased likelihood of engine malfunction. Further, the solid propellant rockets of the SLV-3 cannot generate as much thrust as liquid-fuel engines (and thus have a lesser payload- lift capability[11] In this regard, it should be appreciated that India is currently designing a liquid-fuel rocket which, in combination with solid fuel rockets, will form the PSLV power plant.

In sum, it is probable that, given a political decision to manufacture nuclear bombs and a missile delivery system for such weaponry, India could have an operational IRBM force by the end of the decade. Indeed, a senior ISRO official has observed that India could develop an IRBM prototype within two years.[12]

The SLV-3 was designed and developed to put the 88-pound Rohini satellite into near-earth orbit. Its second flight on 18 July 1980 was successful, making India the sixth nation to orbit a satellite of its own creation.



Factors Influencing India's Decision to Develop IRBMs

Prime Minister Indira Gandhi has repeatedly maintained that India's nuclear program is dedicated to peaceful and constructive purposes. However, many influential figures have articulated the view that development of nuclear weaponry is imperative. The late Air Chief Marshal P. C. Lal, former head of the Indian Air Force, asserted that "India has the capability to make the atom bomb at short notice and should integrate it in its military arsenal and build up its defence strategy and tactics around it." He further advocated the establishment of training programs to familiarize Indian armed forces with nuclear warfare.[13] K. Subrahmanyam, director of the Institute for Defence Studies and Analysis (an autonomous but government-funded body that serves as a principal actor in the formulation of defense policy), observed that "India has to keep a few steps ahead of Pakistan in nuclear weapon technology and develop the infrastructure to be in a position to deter Pakistan when it reaches nuclear capability."[14] If Pakistan does in fact explode a nuclear device, pressure applied by India's "nuclear bomb lobby" may prove irresistible. If the decision to develop nuclear weaponry is made, the question of an appropriate delivery vehicle must be addressed.

Pakistan

There is no need to employ ballistic missile assets against Pakistan. Strike aircraft presently maintained by India (namely, the Canberra medium bomber, the Anglo-French Jaguar, and the Soviet MiG-23 Flogger, along with the French Mirage 2000 to be acquired during 1984-85) can hit targets throughout Pakistan with nuclear bombs.

It should be noted parenthetically that there is no uniformity of opinion within India regarding the indispensability of countering Pakistani nuclear weaponry with equivalent Indian weaponry. Rather, some analysts believe that a Pakistan armed with several crude nuclear bombs could be readily defeated by India's overwhelming conventional strength.[15]

China

India considers China to be its chief strategic threat. This perception results in part from the severe defeat suffered by New Delhi in the 1962 Sino-Indian War. India reacted to this defeat by substantially augmenting military force levels along its northern and northeastern borders. Today, an appreciable percentage of India's ground and air strength is oriented toward China. However, India's conventional arms cannot offset the threat presented by China's medium- and long-range ballistic missile inventory.

India is endeavoring to meet the Chinese threat by diplomatic as well as military means. In December 1981, efforts to resolve Sino-Indian differences regarding demarcation of their common border were reinstituted after twenty-one years; subsequent rounds of talks occurred in May 1982 and January 1983. It is far from certain, however, that these border negotiations will be satisfactorily concluded. Thus, for example, an exacerbation of tensions between India and Pakistan, a principal Chinese ally, could lead to a termination of discussions. The talks could also collapse if India and China are unable to overcome decades of ill-feeling and mutual suspicion. In such circumstances, India's possession of an IRBM force would prove of marked utility, serving to inhibit active Chinese intervention in any future Indo-Pakistani conflict and deter a Chinese attack against India.

Indian Ocean

India appreciates that its regional maritime interests can be secured only through an increased power presence. This in large measure accounts for the emphasis being given to the development of a blue-water navy. The addition

of ballistic missiles to New Delhi's weapon inventory would materially enhance its ability to project military force throughout the Indian Ocean. Increased attention paid to Indian security concerns by outside powers operating in the region (for example, the United States, with its Diego Garcia base) would prove an attendant benefit.

psychological and prestige factors

India wishes to be recognized as a technologically advanced state. The desire to instill this perception was, in addition to military and scientific considerations, a driving force behind the 1974 explosion of a nuclear device. Similar motivations have impelled the establishment of the space program and, to a great degree, stimulate interest in the development of IRBMs.

The political significance of an IRBM force is also not lost on the Indian leadership. Only a few major powers have a ballistic missile production capability. Should India join this group, it would doubtless facilitate efforts at realizing an international security role commensurate with its size and potential. Furthermore, New Delhi would be able to resist the strategic demands of great powers that might otherwise have to be accommodated.[16]

nonaligned movement

Maintenance of India's status as a leader of the nonaligned movement is one of Mrs. Gandhi's central concerns. The manner in which procurement of nuclear weapons and carrier missiles would impact on this policy objective is therefore an issue of considerable moment. In consequence, the Indian government must weigh the likelihood of ballistic missile production raising India's stature in the Third World or, in the alternative, isolating New Delhi within the nonaligned movement by generating apprehension regarding Indian intentions.

economic factors

India's space program expenditures totaled $330 million during the period 1962-80. The relative frugality of this enterprise resulted in part from the willingness of the Soviet Union and the European Space Agency to launch Indian satellites at little or no cost. The dramatic growth of space activity in the 1980s will necessitate a financial outlay of approximately $1.1 billion, a figure that will increase appreciably if space technology is applied to defense requirements. However, such amounts are far less than the costs associated with India's present force modernization effort. In 1979, India signed a $1.7 billion contract with the United Kingdom for Jaguar strike aircraft; in 1980, weapon procurement agreements totaling more than $2 billion were concluded with the Soviet Union and West Germany; and in 1982, India purchased Mirage 2000 multimission aircraft from France at a cost of nearly $1 billion. Therefore, it would appear that, if deemed militarily imperative, economic factors will not dissuade the Indian government from developing a ballistic missile force.

THERE IS NO EVIDENCE to suggest that New Delhi is currently employing space program assets to satisfy defense requirements. It must be recognized, however, that many of the accomplishments of India's space scientists have direct military applicability. Further, the lead time needed to convert satellites and launchers from civilian/scientific to military end use will diminish as India's space effort becomes more sophisticated. Undoubtedly, India's leadership would authorize such a program reorientation should this course of action be deemed advantageous.

Soviets Developing 12-Man Space Station

Work includes new launcher; military objectives dominate effort, but scientific, lunar, planetary goals involved

By Craig Covault

Washington—Soviet Union is developing a 220,000-lb. military/scientific space station to be manned permanently in earth orbit by about 12 cosmonauts following launch in the mid-1980s on board a 10-14-million-lb. thrust booster more powerful than the U. S. Saturn 5.

Establishment of the station will raise concern over increased Soviet strategic capability. Military objectives are expected to dominate the multidisciplinary station and could include photo and electronic intelligence and the first large-scale development of space-based, directed-energy weapons.

The massive new booster and space station will provide the USSR with a solid base on which to mount the first manned missions to Mars in addition to initial Soviet manned lunar flights. The station will, for the first time, involve large numbers of persons permanently working in orbit; a fundamental step toward establishment of colonies in space.

In addition to resumption of substantial work on a Saturn 5 class vehicle, Russian emphasis is expected soon on other Soviet heavy boosters. This indicates the U. S. may be entering an era in which extensive Soviet launch vehicle capabilities alone could be a dominant factor in the strategic use of space compared with even the substantial benefits expected from the U. S. space shuttle.

The 220,000-lb.-class station will be about 10 tons larger than the U. S. Skylab space station and dwarf the 42,000-lb. Russian Salyut station currently in operation. Analysis indicates the booster will be about 300 ft. long with a 50-ft. base diameter, housing 24-36 first-stage engines generating 10-14 million lb. of liftoff thrust. The U. S. Saturn 5 was 363 ft. tall and had a 33-ft.-dia. base with five Rocketdyne F-1 first-stage engines generating a total of 7.5 million lb. of thrust.

The Soviets earlier attempted development of their Saturn 5 class booster in the late 1960s but then mothballed the development after three flight failures (AWAST Apr. 9, 1973, p. 21) and the achievement of the first lunar landing by the U. S.

In addition to renewed development of their Saturn 5 class booster, the Soviets are expected to make increased use of their largest operational booster, the Proton, which has a maximum payload-to-orbit capability of about 45,000 lb., compared to the U. S. Saturn 1B, which had about a 36,600-lb. capability to low earth orbit and the operational Titan 3D with a 30,000-lb. capability.

The Soviets have stated consistently that their ultimate goals in space are per-

Reproduced with permission of the copyright holder from Covault, Craig. Soviets developing a 12-man space station. Aviation week & Space Technology, v. 112, June 16, 1980: 26-29. (c) Aviation week & space technology, McCraw-Hill, Inc.

manently manned space stations and manned flights to the planets, primarily Mars. The two new developments are in direct line with those goals. The Soviets have consistently played down the significance of the Apollo lunar landing program, but U.S. analysts believe this equates to "political sour grapes." With an operational booster capable of placing at least 220,000 lb. in low earth orbit, a lunar landing would be well within reach of the USSR as a stepping stone to Mars. Pursuit of in-orbit vehicle assembly facilitated by the large crew of cosmonauts planned for the space station could assist both manned lunar and manned Mars mission activities.

Current work on the giant new booster could result in a launch attempt as early as 1983, U.S. analysts believe. Launch of the space station will be dependent on booster performance and could occur as early as 1985, U.S. analysts said.

In-orbit resupply and crew change to keep the large new Soviet station permanently manned is expected to involve another major Soviet development also under way. U.S. analysts have reaffirmed that development of a Soviet winged, manned reusable spacecraft is continuing with first launch on an expendable vehicle expected by about 1985 (AWAST Nov. 6, 1978, p. 19; Mar. 20, 1978, p. 14). This winged reusable vehicle will have nowhere near the payload capacity of the U.S. space shuttle but would be a cost-effective space station resupply vehicle. It is comparable to the USAF/Boeing X-20 Dyna Soar program, which was envisioned for space station resupply prior to its cancellation in the 1960s.

The U.S. plans nothing approaching the scale of space activity contemplated by the Soviets with their new developments, although the U.S. space shuttle will provide far easier and less expensive access to space through the 1980s than the Soviet capability will allow. What the current space shuttle program lacks, however, is a financial and planning commitment to expand the orbital stay time and electrical power capabilities of the vehicle and to exploit the shuttle's capability by moving toward space station type platforms that can fly manned missions between shuttle visits. The large booster and station developments should help the Russians maintain a lead in the important area of long-duration manned flight.

Impact of a large permanently manned Soviet space station has already been discussed by the Defense Dept. and the National Aeronautics and Space Administration.

The Defense Dept. and NASA last year jointly initiated examination of the implications of such a development. NASA Administrator Robert A. Frosch told Congress the impact on the U.S. of an operational permanently manned Soviet station "could be severe in the sense that suddenly there would be a change from experimentation to [an] operational status. I think people in general would consider it a serious event" (AWAST Apr. 9, 1979, p. 21).

Explosive expansion of Soviet space program activity over the past several years, especially in the manned area, has been possible because the Russians have been providing their program with real funding increases of 3-5% per year, a sharp contrast to the U.S. congressional and presidential attitude toward the U.S. program since the end of the Apollo project.

The Russians are believed to have at least 100,000 scientists and engineers largely devoted to space program goals, and they have been developing an average of three entirely new spacecraft types every year. New launch vehicles have been

developed at a rate of one every five years by the Russians.

The Soviets last year demonstrated their ability and willingness to devote, on relatively short notice, large numbers of expensive space vehicles to obtain nationally important data. During 1979 the Russians flew 10 recoverable film reconnaissance spacecraft on announced earth resources missions that U. S. analysts believe were launched specifically to assess world wheat crops. This was to provide the Soviets with market data in a year when their own wheat crop was below expectations.

Soviet spacecraft are expected to become larger and more complex requiring expanded use of the Proton booster, the largest operational launch vehicle in the world. Increased use of the Proton could result in an overall yearly reduction in Soviet launches as individual Soviet spacecraft become heavier and are given more capability. During 1979 the Soviets launched 87 missions carrying 124 satellite payloads. The U. S. launched 16 missions carrying 18 payloads. At least 59 of the Russian missions were military compared to five U. S. military missions last year.

The Proton is the same vehicle used to launch the Salyut space station, and it also is expected to be used to launch the new delta-winged manned reusable space vehicle. The Soviets will have to man-rate the Proton for this task, a factor that would probably involve some system rework on the vehicle since in its unmanned role the Proton has a somewhat higher failure rate than smaller Soviet boosters.

Expanding Booster Capability

While the U. S. begins to operate the 65,000-lb. payload space shuttle the Soviets will be expanding their already formidable booster capability by bringing on line their Saturn 5 class vehicle, increasing use of the standard Proton, and possibly adding a liquid oxygen/hydrogen upper stage to the Proton launcher.

The Soviets have never flown an oxygen/hydrogen upper stage, although U. S. researchers have been expecting to see this development relatively soon. Such a stage on the Proton could greatly increase the amount of payload the Soviets could launch into geosynchronous orbit.

The new Saturn 5 class booster is not expected to use oxygen and hydrogen stages as did the U. S. Saturn 5. Lack of high-energy second and third stages like those on the U. S. Saturn 5 is one reason the Soviet vehicle is expected to have a payload-to-orbit capability comparable to the Saturn 5 but to utilize a first stage with possibly twice the thrust of the Boeing S-1C, which was the Saturn 5's first stage.

Payload Weight

Earth escape payload for the Soviet vehicle will be comparable in weight to that of the Saturn 5. Earlier tests of the initial version of the Soviet vehicle failed in November, 1972; June, 1971, and June, 1969. As recently as two years ago, development of the vehicle was considered by U. S. analysts to be "on the back burner," but the development has now resumed at a pace keyed to launch of the large space station in the mid-1980s.

Another significant development in the heavy booster area involves the Russian SS-9 intercontinental ballistic missile. SS-9s have been used routinely as space launchers for many years, but recent data indicate a third stage is now added on some missions to increase the size of the payload that can be launched. SS-9 operational ICBMs now are being replaced by

the SS-18, and analysts believe it is possible that many more SS-9s will be used for space launch missions, further increasing the overall Soviet payload-to-orbit capability.

While booster power is increasing, so are Soviet electrical power capabilities in space. U. S. analysts foresee increased use of nuclear reactors for electrical power on Soviet spacecraft. Loss of the Cosmos 954 reactor-powered spacecraft over Canada, which caused a major international incident, has not slowed the Soviet reactor program, and U. S. analysts expect to see continued use of the reactor-powered radar ocean surveillance spacecraft to help expand Soviet naval warfighting capability far beyond previous bounds. U. S. analysts would not be surprised to see reactors placed on future Russian television broadcast and other communications spacecraft in the 1980s.

Reactor work in space could be important for development of directed-energy weapons in space. No Soviet laser or other directed-energy tests in space have occurred, but the U. S. believes it likely the Soviets now have an operational ground-based antisatellite laser and the basing of that system in space is a likely area of Soviet development over the next few years.

Activities on the Salyut 6 space station are a major stimulus to the new Russian space developments and already approach permanent station status but with only a two-man crew. Some U. S. analysts believe that Soviet unmanned planetary missions are receiving fewer resources now in order to pour more funds into the manned program.

Increase in size of the existing Salyut space station design is a priority in the Soviet program. One way this can be done is to leave a Soyuz orbital module docked with the vehicle as the standard crew-carrying Soyuz descent module and service module separate for a return to earth.

Salyut 6 has only two docking ports, a limiting factor in this type activity. U. S. analysts believe that as early as the next Salyut, Salyut 7, the Soviets can be expected to utilize more than two docking ports on their Salyuts in order to bring modules to the station that can be left, thus increasing the habitable space while also allowing docking ports for Soyuz return vehicles and Progress tanker resupply missions.

Soyuz T-2 spacecraft that returned Cosmonauts Lt. Col. Yuri V. Malyshev and Vladimir V. Aksenov to earth June 9 after a four-day mission, three of those days on Salyut 6, is an uprated Soyuz that is expected to be used until the Russians bring their reusable winged vehicle on line in connection with the massive space station in the mid-1980s.

The Soyuz T design includes solar arrays and an improved main propulsion and attitude control system assisted by a digital computer.

These changes should enable much more mission flexibility than the older Soyuz design, so limited on stored battery power and maneuvering propellant that it has been forced to abort space station linkups at high Salyut altitudes whenever problems occurred in the final rendezvous and docking sequence.

These new Russian developments of expanding booster power with a Saturn 5 class vehicle, development of a permanent space station larger than Skylab and planned use of winged, reusable space transports indicate that the decades the 1980s and 1990s will be full of intense Russian manned space activity. Many managers in the U. S. space program hope the military strategic and scientific significance of this major Russian development push will not be lost in planning for the space shuttle and will stimulate full use of its capabilities.

The National Security Council has recognized this Soviet advancement and during White House discussions late last year on increased space shuttle development funding that threatened the operational use of the shuttle, called President Carter's attention to the Soviet development push.

"The currently operational military and civil Soviet manned program could provide them with significant scientific, technical, political and strategic advances that cannot be overcome with a U. S. space program operating solely on expendable launch vehicles," a briefing to the President stated. "If we do not expend the thought, the effort and the money required, then another more progressive nation will."

SALYUT

SOVIET STEPS TOWARD PERMANENT HUMAN PRESENCE IN SPACE

A TECHNICAL MEMORANDUM

DECEMBER 1983

Technical Memoranda are issued by OTA on specific subjects analyzed in recent OTA reports or on projects presently in process at OTA. They are issued at the request of Members of Congress who are engaged in committee legislative actions which are expected to be resolved before OTA completes its assessment.

CONGRESS OF THE UNITED STATES

Foreword

As the other major spacefaring nation, the Soviet Union is a subject of interest to the American people and Congress in their deliberations concerning the future of U.S. space activities. In the course of an assessment of Civilian Space Stations, the Office of Technology Assessment (OTA) has undertaken a study of the presence of Soviets in space and their Salyut space stations, in order to provide Congress with an informed view of Soviet capabilities and intentions.

The major element in this technical memorandum was a workshop held at OTA in December 1982: it was the first occasion when a significant number of experts in this area of Soviet space activities had met for extended unclassified discussion. As a result of the workshop, OTA prepared this technical memorandum, "Salyut: Soviet Steps Toward Permanent Human Presence in Space." It has been reviewed extensively by workshop participants and others familiar with Soviet space activities.

Also in December 1982, OTA wrote to the U.S.S.R.'s Ambassador to the United States Anatoliy Dobrynin, requesting any information concerning present and future Soviet space activities that the Soviet Union judged could be of value to the OTA assessment of civilian space stations. The result of this request is appendix A of this technical memorandum: "The Soviet Salyut Space Program: Space Station, Spacecraft, Support, and Training Facilities" is an official summary of Salyut space station activities, provided to OTA by Dr. Balayan, Vice-Chairman of the Intercosmos Council of the U.S.S.R.'s Academy of Sciences. OTA appreciates the cooperation of Ambassador Dobrynin and the Soviet Academy in providing this information. This appendix is of particular interest in that such information is seldom provided to American agencies through official Soviet channels.

Appendix B is a paper prepared for OTA by Geoffrey E. Perry, head of the Kettering Group in England. This paper, "Soviet Space Stations: Achievements, Trends, and Outlook," provides an independent view of Soviet accomplishments in this area; it is based, in part, on the Kettering Group's long-term monitoring of audio communications between the Salyuts and Soviet ground stations.

Those individuals acknowledged in appendix C provided information during the course of the study and/or reviewed the draft report.

Introduction

A number of citizens of the Soviet Union, and their guests from other countries, have visited the Earth's lower space regime; the Soviet in-orbit space infrastructure, primarily the Salyut space stations (or, as the Soviets say, "orbital stations"), has housed and supplied them there, more or less continuously, for over a dozen years. During this period the total number of hours that Soviet cosmonauts have spent in space has overtaken and is now much greater than the corresponding total for U.S. astronauts. By all accounts, the Soviets are more knowledgeable than the United States in space biology and medicine; in a number of technical areas, notably in the use of automated docking systems, they routinely use techniques that the United States has never demonstrated. It is true, on the other hand, that the Space Shuttle now gives the United States significant capabilities that the Soviets do not have, but it is widely believed on the basis of photographic evidence available from unclassified sources that the Soviet Union is developing both a small space plane and a heavy-lift shuttle expected to be capable of propelling more massive payloads into low-Earth orbit than can its U.S. counterpart.

The Soviet space station program is the cornerstone of an official policy which looks not only toward a permanent Soviet human presence in low-Earth orbit but also toward permanent Soviet settlement of their people on the Moon and Mars. The Soviets take quite seriously the possibility that large numbers of their citizens will one day live in space. Although the Soviets do not often directly communicate detailed results of what has been learned by and from the cosmonauts aboard Salyuts, enough information is available to conclude that they are accomplishing much more than rudimentary scientific investigations: they are providing the data, information, and experience required to design habitats and equipment which will allow individuals to reside for the long-term in space.

The Soviet approach to the development of space capabilities differs significantly from the American. Whereas the United States tends to advance from one space capability to the next by quantum leaps, the Soviet Union tends to modify and adapt technology that is already in hand, thereby increasing its capability in a seemingly more evolutionary or progressive fashion. By thus relying on systems flight-proved in earlier space programs, the Soviets may have been able to restrain costs and minimize the time spent in development and construction. The Soviet space program and the U.S. satellite communications industry are similar in that both allow for the establishment of gradually evolving spacecraft design, and it may be advisable for the United States, in other selected areas of space applications, for example, to adopt some form of the Soviet strategy. Already, NASA's Solar System Exploration Committee (SSEC), emphasizing the importance of system heritability, has advocated a similar approach for planetary science.

The relative merits of automated and human capabilities for performing work in space or, more precisely, the criteria for establishing the optimal mix of the automation and the human presence for particular tasks, are the subjects of considerable debate in the United States. Although the amount of time in space that American astronauts have amassed is nontrivial, there is a certain degree of unreality about this debate because it cannot yet be grounded in extensive experience. The Soviet Union, on the other hand, can draw on a much greater fund of experience as they implement plans for integrating human and machine capabilities for work on future space stations.

Perhaps the most important point to be made here is that the United States and the Soviet Union have cast the issue of humans versus machines in different terms. U.S. space policy is to explore and study space and to use it for general human benefit—and, where appropriate, to involve human beings in actual spaceflight. In addition, both the United States and the Soviet Union use their spaceflight programs involving people to enhance their national images. Soviet space policy, however, goes further; it includes the goal of learning how human beings may reside permanently in space, both as an end in itself and as a means of serving their national purposes. To date, the United States has not committed itself to permanent human occupancy of space as a national goal.

Executive Summary

The launching of Sputnik 1 initiated a space race that led to the landing of astronauts on the Moon; today the United States and the Soviet Union are well aware of their relative strengths and weaknesses in space activity. In most areas of space science and space applications—best exemplified, respectively, by the Voyager missions to Jupiter and Saturn, and the burgeoning satellite communications industry—the United States, through steady, long-term effort, seems to have gained a substantial lead over the Soviet Union.

In human spaceflight, the picture is less clear because the countries have taken quite different approaches. In some respects, the activities of the two countries in this arena have resembled the race between the tortoise and the hare: while the Soviet effort has featured apparently steady, incremental progression along well-defined lines of development, the United States has typically played catchup, using its strong technological capacity to produce space achievements of startling virtuosity. Continuing development on both sides has been fueled by a combination of political, economic, and military motives, in different order of importance at different times.

The divergent approaches of the two countries have led to two very different types of current human spaceflight capability. The Soviet Union has, since 1971, pursued a more-or-less continuous program of development of space stations in low-Earth orbit (LEO). With the sixth operational model of the Salyut series now flying, Soviet cosmonauts have logged over three times the U.S. total of crew-hours in space, and accumulated extensive experience in the conduct of flight operations, experimentation, and Earth observation in trips that last for months. However, they are currently restricted to the use of relatively small, expendable launch vehicles for crew transportation and resupply. The United States, on the other hand, has an operational space Shuttle which permits the routine ferrying of crews and large payloads into orbit for over a week, currently at the rate of some 5-6 flights per year. The Shuttle is reusable, its staytime in orbit could be increased, and the planned fleet of four Orbiters could provide staytime on the order of months per year. But an individual unmodified Orbiter does not provide a habitation combining large volume, high power, and long duration needed for many of the in-orbit research and development activities of interest, particularly to the life sciences and some in the private sector.

The National Aeronautics and Space Administration is now considering "the next logical step" for its space program: the establishment of a potentially permanent human presence as part of an actually permanent LEO infrastructure, i.e., what NASA describes as a civilian space station. If the administration formally proposes to begin work on such infrastructure, then Congress may find that a detailed examination of the Soviet human presence in space, the Salyut space stations, and their associated space vehicles, can provide a useful frame of reference.

Early in this century, Konstantin Tsiolkovsky, a Russian scientist and engineer, provided the theoretical underpinnings for the Soviet space program with his visionary writings about the use of orbiting stations as a springboard for exploring the cosmos. One can still find the influence of his theories in the statements of modern-day Soviet leaders.

But Soviet scientists and technicians have found that the road to realizing their dream is a long and difficult one. After initial successes with Sputnik and the early orbital flights of cosmonauts in the one-seat Vostok capsule, the Soviet space program began to feel the limitations of its technology. The 6-metric-ton (tonne; one tonne = 2205 lbs) Voskhod flew only twice, Voskhod 1 with three crewmembers, Vockhod 2 with two. Two years later, in 1967, a new space vehicle debuted with Soyuz 1. Despite the death of the first Soyuz pilot in a crash landing, the Soyuz-class ship eventually became the principal means of putting cosmonauts into space. After 12 years of Soyuz operations, a new design, Soyuz T, made its inaugural flight in 1979.

In the late 1960's, the Soviets appeared to be intent on sending cosmonauts to the Moon, but, in view of the success of the U.S. effort to do so, they eventually settled for landing automated

probes on the lunar surface. Subsequently, the focus of the Soviet manned space program shifted exclusively to the establishment of a strong capability for near-Earth orbital operations, i.e., the development of space stations and associated space vehicles. When Soyuz 4 docked with its sister ship Soyuz 5 in January 1969, the Soviets called the resulting complex "the world's first space station," although the two craft had no connecting passageway between them. Salyut 1, which provided one continuous volume capable of supporting human habitation for time-periods of the order of months, went into orbit in 1971; the most recent of the series, Salyut 7, was launched in 1982 and remains operational today.

Some of the Salyut stations were apparently military in function; others seem to have been primarily civil. With Salyut 6 and 7, the distinction became blurred; it may be that the military no longer has a separate Salyut program. The Soviets have maintained total secrecy in military operations, but they have gradually become more open with their civilian programs, broadening the makeup of their crews to include members from Eastern Europe and other Soviet-bloc countries, France, and, soon, India. Although any joint U.S.-Soviet effort (e.g., the symbolic joining of the Apollo and Soyuz in orbit in 1975) currently seems unlikely, future Soviet missions will probably continue to be international to some degree.

The fact that the Soviet technological base remains relatively narrow seems to be closely coupled with the infrequency with which rapid innovation is achieved, both in Soviet industry generally and in the Soviet space program in particular. Although Soviet spacecraft designers rely heavily on automated control with cosmonauts as backups, crewmembers have, in many instances, assumed broader duties to make up for failures in automation. In any case, Salyut has afforded its crews of engineers and cosmonauts extensive experience in conducting operations in space. Precisely how this experience will be put to use in future operations is unclear.

Salyut may be the penultimate step leading to a permanent, large-scale human presence in space. Before that can be accomplished, the Soviets may have to achieve success in developing a heavy-lift launcher, similar to the U.S. Saturn V, which would allow for the construction of a second-generation station out of much larger modules. A vehicle along the lines of the U.S. space shuttle to provide routine access to a near-Earth station would also be desirable, and indeed Western sources believe that the Soviets may be developing a heavy-lift, reusable shuttle that could carry twice the payload of the American craft. In addition, the Soviets have already conducted tests for a 1-tonne prototype of a 10- to 20-tonne space plane.

With such spacecraft in their fleet, the Soviets would possess both a "space truck" and a light-duty ferry vehicle to provide routine service to an expandable infrastructure in space. With this infrastructure as a hub of operations, extension of human activity to geostationary orbit, the Moon, and even Mars becomes technically feasible—indeed Soviet planners have frequently mentioned each of these as an objective. That previous U.S.S.R. efforts to reach Mars have met with failure may, in the near term, have militated against their initiating programs to send vehicles to the outer planets and deep space. But it is unlikely that the Soviets see these failures as anything more than temporary setbacks, especially in view of U.S. success in planetary exploration generally and their own success in the very difficult task of returning data from the surface of Venus—a feat that the United States has yet to match. Indeed, a Salyut space station may provide the core element of a future base necessary to ensure success of future trips to Mars.

Early Soviet Manned Spaceflight

Historical Background

A central element in the Soviet Union's exploration and exploitation of space has been its reliance on Salyut-class orbital stations occupied by cosmonauts. Seven of these stations have been officially announced by the U.S.S.R. as of December 1983. These facilities have begun to realize the possibilities envisioned by Konstantin Tsiolkovsky, the Russian scientist/engineer who is considered the founder of Soviet astronautics. Early in the century, he described how orbital stations might be built, noting that they represented the very heart of a program of space conquest.

Typical of his observations is this 1923 description of the construction of a system of Earth-orbiting stations:

> We take off in a space ship . . . and stay at a distance of 2000-3000 versts [each verst equaling 0.6629 mile] from Earth, as its Moon. Little by little appear colonies with implements, materials, machines, and structures brought from Earth. Gradually, independent production, though limited at first, will develop.[1]

Reinforcing the conviction of Tsiolkovsky, the late Leonid Brezhnev, then President of the Soviet Union, remarked in 1978:

> Mankind will not forever remain on Earth, but in the pursuit of light and space will first timidly emerge from the bounds of the atmosphere, and then advance until he has conquered the whole of circumsolar space. We believe that permanently manned space stations with interchangeable crews will be mankind's pathway into the universe.[2]

As the launch of Sputnik 1—the Earth's first artificial satellite, on October 4, 1957—opened the path toward realization of Tsiolkovsky's visions, so the Soviet Union's increasing ability to transport people into space in the 1960's, 1970's, and 1980's has added substance to Brezhnev's declaration. At least since the early 1970's, the Soviet Union seems to have taken a slow, more-or-less steady approach toward fulfilling the aspirations of its engineers and political leaders.*

Vostok

Vostok (meaning "East"), a one-seater spacecraft, was the first Soviet vehicle to carry a cosmonaut into orbit.** Six Vostoks were launched between April 1961 and June 1963; they remained in orbit for periods ranging from 108 minutes to nearly 5 days. Weighing 4.7 metric tons (tonnes) and simple in design, the vehicle consisted of two modules: an almost spherical capsule which carried the cosmonaut, and an equipment package containing fuel, life-support gear, batteries, attitude-control thrusters, and a retrorocket to slow the vehicle for reentry into the Earth's atmosphere.

Vostok's pilot was little more than a passenger. With no orbital maneuvering capability designed into the system, the pilot had few responsibilities for control of the spacecraft.

On two occasions, pairs of Vostoks flew concurrently. Two A-1 vehicles launched Vostoks 3 and 4 from the same cosmodrome within 24 hours;*** Vostoks 5 and 6 were similarly launched within 48 hours. In the second case, the Soviets showed they could launch at precise times. In 1962 and 1963, the U.S. manned spaceflight program could not match this achievement, the Mercury program being plagued by a series of "holds" and postponements.

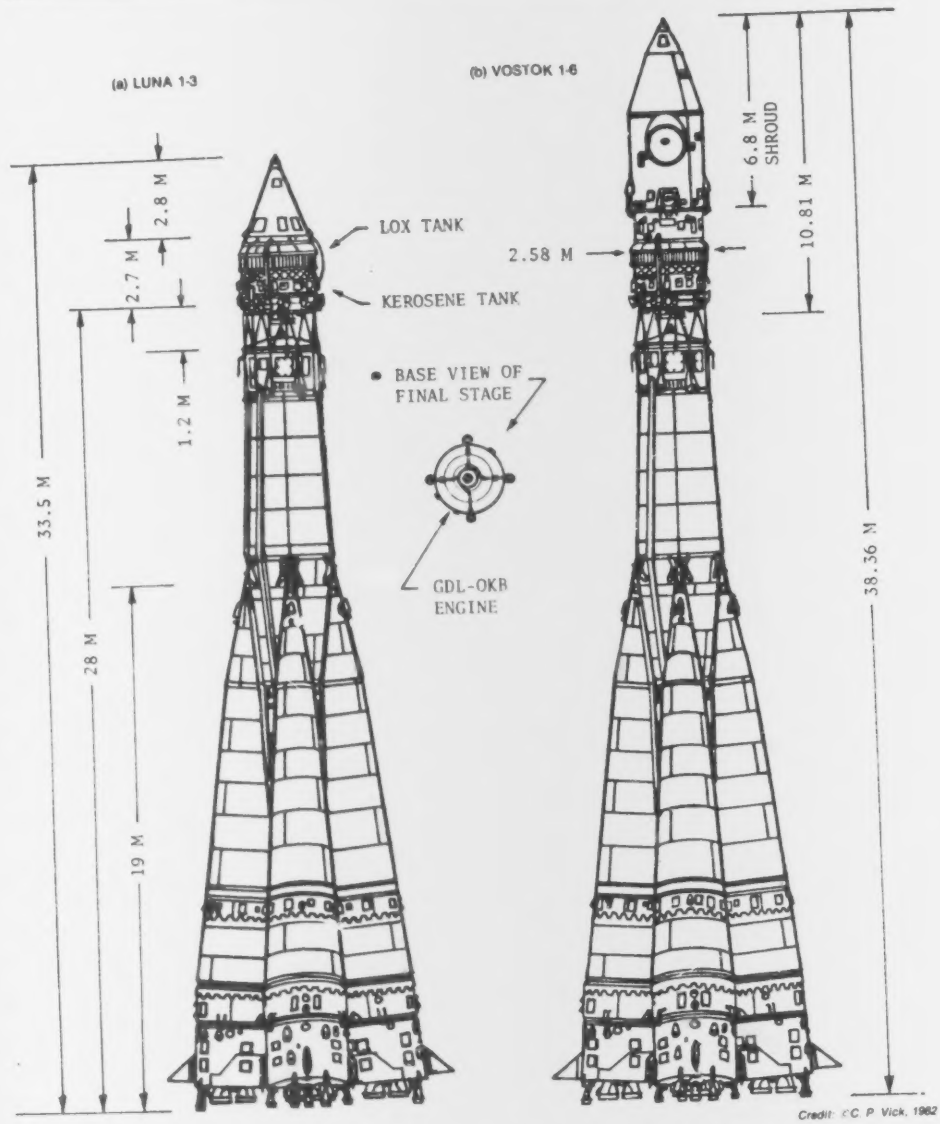
[1] K. E. Tsiolkovsky, *Collected Works*, vol. 2, Moscow, Izdatel'stvo AN U.S.S.R., 1954.

[2] Kenneth Gatland, chief author, *The Illustrated Encyclopedia of Space Technology* (London: Salamander Books, Ltd., 1981), p. 214.

*Many informed Western observers, as well as official Soviet historians and publicists, would extend this characterization to the early years of the Soviet program. Others, however, disagree, arguing that, especially in these early years, the appearance of an evolutionary course disguises a number of false starts, midcourse corrections, and radical changes of plan.

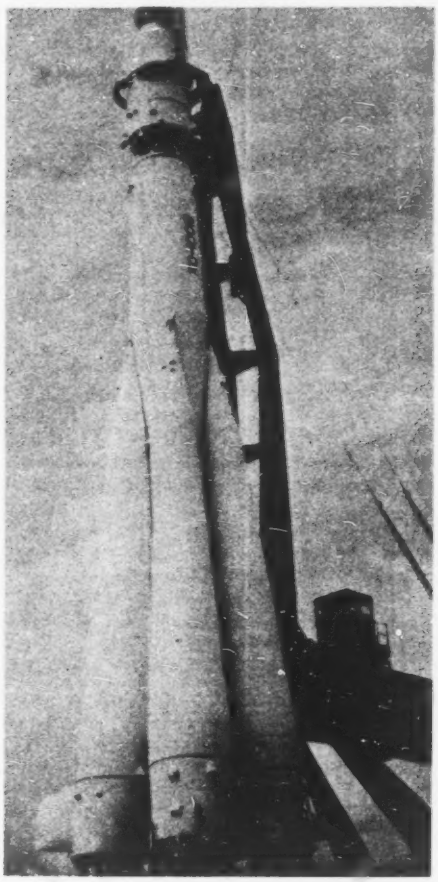
**In preparation for the first manned flight, the Soviets, in 1960 and 1961, launched at least four Sputniks with animals aboard in order to determine how they were affected by the operation of various spacecraft subsystems. These included the launch system, onboard life support and environmental control, and the reentry and recovery system.

***The designations "A," "D," "G," etc., are based on an alphanumeric classification system devised by the late Charles Sheldon of the Library of Congress. Another system designates the launch vehicle with an "SL" and a number. Thus, the "A-2" vehicle is the same as the "SL-4."



Luna 1-3 (a); Vostok 1-6 (b)—standard launch vehicle with the first type of added upper stage A-1 (a) as used to launch the first three Luna spacecraft; (b) as used to launch the six Vostok manned spacecraft

Vostok Booster



These simultaneous flights not only served as tests of ground control and launch turnaround capability, but also, as precursors of future rendezvous and docking missions, allowed a determination of how closely spacecraft could be positioned in orbit without specific orbital maneuvers. The orbital injections were so accurate that the first pair coorbited and the second passed within 5 miles of each other in noncoplanar orbits.* With these Vostok missions, the Soviets also demonstrated the capability to handle communications with two spacecraft simultaneously.

Another highlight of the Vostok program took place in June 1963 when Valentina Tereshkova became the first woman in space. Flying in Vostok 6 for 48 orbits around the Earth, she tallied more flight time than all the male astronauts in the U.S. Mercury program. Although relatively untrained and rumored to have been ill throughout her flight, Tereshkova at least achieved substantial publicity.

Voskhod

In October 1964 and March 1965, the Soviet Union launched the 6-tonne Voskhod ("Sunrise"), a modified Vostok capable of carrying two or three cosmonauts on daylong flights. Because the Voskhod was used only for these two flights, some Western experts believe it was intended primarily to preempt the U.S. Gemini program, which would put two astronauts in one vehicle, one of whom would "walk" in space. Voskhod had approximately the same pressurized volume as did Vostok, but more volume was made available for habitable crew space because the ejection seat and rails were removed and because the crew wore overalls instead of bulky pressurized space suits.

Voskhod 1, weighing 5.3 tonnes, had a three-person crew. In Voskhod 2, which weighed 5.7 tonnes, one of the crew couches was replaced with an inflatable airlock and associated hatches to allow for extravehicular activity (EVA), or "spacewalking." During the flight one of the crew accomplished the first spacewalk of some 10 minutes duration.** The Voskhod program included the first flight of a physician to conduct in situ observations; it also tested new TV and audio communications equipment, evaluated techniques for spacecraft orientation, and employed a new solid-rocket, soft-landing system. It did not, however,

*The orbits of Vostok 5 and 6 were in fact separated by almost 29° at their point of nearest approach, with the result that their relative velocity was approximately 12,000 feet per second. This hardly could be counted as a rendezvous.

**The cosmonaut spent a total of some 22 minutes under space conditions—12 minutes outside the spacecraft, and the preceding 10 minutes in a depressurized, inflatable airlock.

Voskhod-2 (a); Soyuz T (b)—standard launch vehicle with the improved upper stage A-2 (a) as used to launch the two Voskhod manned spacecraft; (b) as used to launch the Soyuz T manned spacecraft

include a launch escape system. As the first of a series of individually small but cumulatively significant advances in Soviet space capabilities, the Voskhod program brought the Soviet Union's total person-hours in orbit to some 507; by contrast, U.S. astronauts had accumulated 53 hours through Project Mercury.

By the end of the Voskhod program, the Soviet Union was dedicating its engineering expertise to the creation of a more capable spacecraft—the Soyuz ("Union"). During the 2-year hiatus between the flight of Voskhod 2 and Soyuz 1, the U.S. Gemini program of 10 flights accomplished many outstanding first-time achievements; American crewmembers also overtook their Soviet counterparts in flight time, a lead they maintained, through the Apollo-Soyuz Test Project (ASTP) in 1975, until the flight of Soyuz 29 in June 1978. The Salyut 6 missions subsequently reestablished the Soviet lead, more than double the U.S. total.

Soyuz

Building on the technical foundation laid by Vostok and Voskhod, the Soviet Union developed the Soyuz space vehicle. First flown with a pilot aboard in 1967,* Soyuz, the first of the Soviets' truly operational spacecraft rated to carry crew, remains, with evolutionary modifications, the standard vehicle for transporting crewmembers to Salyut ("Salute") space stations. The current design, called Soyuz T, was introduced in 1979. Many Western observers believe that Soyuz was initially developed to serve as part of an ambitious program to send a cosmonaut to the Moon. However, it experienced a number of technical problems, including the inability of the A-2 booster to launch a fully fueled and instrumented spacecraft, launch failures of the medium-lift Proton type D-1-e and the heavy-lift G-class boosters,** and troubles with control systems aboard automated lunar spacecraft. These problems made it impossible to use Soyuz for a manned lunar mission during the late 1960's, when beating the United States to the Moon was, presumably, of high priority. As a result, the Soviets appear to have postponed any such lunar missions indefinitely.

Why were such technical problems not overcome? The conventional explanation holds that the American lunar landings undermined the Soviets' incentive for, and interest in, putting a cosmonaut on the Moon. A fuller appraisal holds that, after Apollo 11, the planned Soviet program would have seemed second rate. The Soviets originally envisioned sending (only) one cosmonaut in a Zond spacecraft to loop once around the Moon (not to make multiple orbits) and probably required an Earth-orbit rendezvous. But the success of Apollo 8 at Christmas 1968 and subsequent near-perfect flights of Apollos 9, 10, and 11, apparently convinced the Soviets to concentrate on other activities. As alternatives that could be achieved, near-Earth, orbiting stations capable of human habitation, and automated probes for lunar sample return (via the Luna series spacecraft) and surface exploration (via Lunokhod 1 and 2) became the new foci of Soviet activities.

Carrying crews of one to three persons, Soyuz has been used to conduct a wide variety of military and scientific experiments. These vehicles are capable of orbital maneuvering, rendezvous and docking, and solo flights with crew aboard for up to 30 days.*

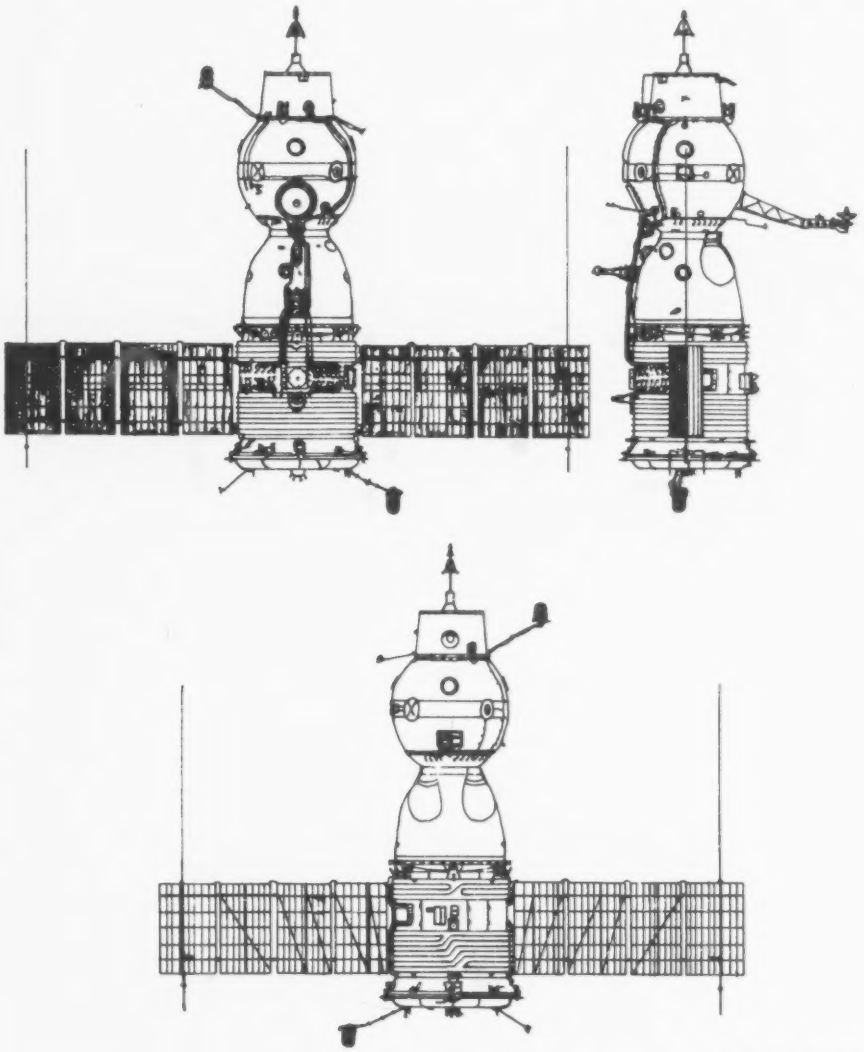
Soyuz is 7 meters in length, 2.7 meters in diameter, and up to 6.8 tonnes in weight, and contains three connected elements that are interdependent for power, thermal control, and propulsion:

- *Command Module.*—Serves as the ascent and descent compartment in which cosmonauts are ferried to and from orbit, as well as the module in which they are stationed during orbital maneuvers. It also contains system function indicators and control panels through which the cosmonauts interact with various automatic systems. The Command Module and the Orbital Work Module to-

*The first flight of the Soyuz in 1967, ended with the death of the pilot in a crash landing; this kind of craft was not flown again until October 1968.

**The G-series booster is comparable to the U.S. Saturn V vehicle.

*Although 18 days is the longest demonstrated flight of a Soyuz craft with crew aboard, the Soviets have repeatedly stated this time could be extended to 30 days. Without crew aboard, Soyuz vehicles are capable of much longer duration in orbit: Soyuz T-1 recorded a flight of 100 days while docked with Salyut 6; Cosmos 613, undocked, remained in orbit for 60 days.



Credit: C. P. Vick, 1983

Soyuz 4: The original Soyuz spacecraft. Average mass: 6,500 to 6,625 kg. Overall length from booster interface to the docking interface: 7.5 m. Body diameter: 2.2 m. Base diameter: 2.72 m. Descent module mass: 2,900 kg. The Soyuz 1-9 spacecraft were never launched fully fueled and fully instrumented. A full weight spacecraft would have weighed approximately 9,000 kg, exceeding the 7,500-kg payload capacity of the Soyuz A-2 booster

gether provide a total habitable volume of nearly 9 cubic meters (one cubic meter = 35 cubic feet), roughly twice that of Vostok; in Soyuz T the habitable volume has been increased to about 10 cubic meters. The slightly bell-shaped Command Module is a "lifting body;" its aerodynamic properties, similar to those of Apollo, are substantially better than those of Vostok, lessening reentry deceleration forces on its crew and enhancing landing zone targeting.

- *Orbital Work Module.*—Nearly spherical in shape, it allows cosmonauts to work, think, eat, relax, and sleep in surroundings that are spacious in comparison with those of the Command Module. The Orbital Work Module is also used as an airlock through which the crew may transfer to other spacecraft or embark on spacewalks; an airtight hatch is located at the interface that secures it to the Command Module.
- *Instrument and Systems Module.*—Contains a series of propulsion, maneuvering, and attitude control engines; associated fuel tanks; and a pressurized forward section holding major portions of the electronics for major operating systems (environmental, attitude control, communications, electrical, and propulsion). In some versions of Soyuz, solar cell arrays protrude, winglike, from opposite sides of this module, and provide charge and recharge of a set of internal chemical batteries. Use of solar panels ceased after Soyuz 11 but was resumed with the Soviet Union's component of the joint U.S.-Soviet Apollo-Soyuz Test Project, Soyuz ASTP,[3] and retained in the Soyuz T.

[3]For a detailed account of this mission, see, Edward and Linda Ezell, *The Partnership—A History of the Apollo-Soyuz Test Project*, in the NASA History Series, NASA SP-4209, Washington, D.C., 1978.

Pre-Salyut Soyuz Space Flights

As the core vehicle for Soviet-manned space activities since 1967, the Soyuz has accomplished diversified objectives, many of them directly related to the growth of the Salyut space station program. Capable of flying with or without crews, Soyuz has served as a test bed to observe the physiological effects of long- and short-term spaceflight on human beings (as well as animals and plants), to evaluate rendezvous and docking techniques, and to appraise Earth remote-sensing equipment and new spacecraft systems.*

In early Soyuz flights, cosmonauts exercised skills later to be integrated into operations of the Salyut space stations. Specifically, the space complex resulting from the docking of Soyuz 4 and 5 in January 1969 was described by the Soviets as "the world's first space station"[4]—a somewhat puzzling description, as there was no connecting hatch. During the few hours when the two craft were linked in power, control, and communications, two cosmonauts from Soyuz 5 donned self-contained life-support systems, left their craft through a hatch in the Orbital Work Module and, using handrails, transferred into the docked Soyuz 4. This orbiting complex provided a total working volume of 632 cubic feet, the largest attained to that date.

Although most observers contend that a true space station should allow its occupants to move from one part of the facility to another without having to resort to spacewalking, the experience gained in the Soyuz 4 and 5 complex was valuable in the design and development of larger space station configurations.

In October 1969, the Soviets launched Soyuz 6, 7, and 8. In spite of their apparent failure to dock two of the vehicles, they succeeded in flying the three spacecraft with their seven cosmonauts in coordinated, close formation. At the time, the Soviets commented that the joint exercise evaluated autonomous navigation devices for use in close-formation flying and achieved a "rational distribution" of control between man and machine.

Acting on the assumption that the construction of future space stations would require a mastery of in-space welding techniques, the Soviets included a test unit on Soyuz 6. The device was operated remotely in vacuo and manually within the pressurized Orbital Workshop Module. Three welding techniques were tried in vacuo: 1) low-pressure compressed arc, 2) electron beam, and 3) arc with consumable electrode. Only the second was reported to be a complete success. More recently, the Soviets claimed those experiments can now be "seen as an impetus to the practical development of space technology."[5]

From its first use in April 1967 to the landing of Soyuz 9 in June 1970, and the initiation of space station operations, Soyuz spacecraft flew 15 persons on eight missions for a total of nearly 44 days of operations in space. At the close of this period, Soviet personnel—on Vostok, Voskhod, and Soyuz spacecraft—had accumulated a total of some 2,550 hours in space. By comparison, the total at this juncture for U.S. Mercury, Gemini, and Apollo spaceflight was far greater, being slightly over 6,260 personnel hours.

An apparent objective of the Soyuz program was to provide a multipurpose spacecraft to be used in connection with an orbital space station. Among its many roles, Soyuz was to be a temporary base for checking out the station, a supply and transport shuttle, and a vehicle for conducting additional independent studies. Given the growing proficiency the Soviets had shown with Soyuz, there remained no major technological barriers to their Salyut space station program.

*Unfortunately, in demonstrating this latitude of functions, four cosmonauts lost their lives in two separate accidents, one in Soyuz 1 and three in Soyuz 11.

[4]This phrase was first used in a question by the Tass correspondent at the Cosmonauts' press conference in Moscow, Jan. 24, 1969. (Summary World Broadcasts, Su/2984/c/4). This same claim could have been made earlier, when two pairs of unmanned Soyuz prototypes previously achieved successful rendezvous and docking—except, of course, that some third vehicle would have been required to ferry a crew to staff them.

Salyut Space Station Characteristics

Because each new U.S. spacecraft system is designed "from scratch," American designers tend to emphasize quantum leaps in capability. By contrast, the Soviets reuse subsystems on different spacecraft whenever possible. For instance, the same propulsion, power, and thermal-control systems may be used on many vehicles. By relying on systems flight-proved in earlier space programs,* the Soviets may have been able to reduce costs and shorten the time spent in development and construction. Still, most of these elements require modification.[6]

The Soviets are believed to have begun work directly related to the development of Salyut space stations in the late 1960's. The first in this series of stations, Salyut 1, was launched in April 1971. To date, the Soviet Union has officially acknowledged that seven of these facilities have been launched, one of which (Salyut 2) broke up in orbit. Cosmos 557, which failed in orbit, is generally thought to have been a Salyut, although the Soviets have not confirmed this inference.[7] ** Only one other spacecraft, Cosmos 382, may have been a Salyut, but the evidence for this view is meager.[8] Though the Soviets experienced numerous failures early in the Salyut program, their strategy of using flight-proved subsystems in new programs to save time and costs was less at fault than was their weakness in the quality control of these subsystems.

Salyut-class space stations utilize several distinct major components:

- *Salyut.*—An orbital laboratory, 13 meters (m; one m = 3.3 ft.) in length, 4.2 m at maximum diameter and weighing approximately 19 tonnes; it provides over 100 m^3 of usable space for up to five crewmembers. The orbits of civil Salyuts (4, 6, and 7) lie between 362 and 338 kilometers (km; 1 km = 0.62 statute mile) above the Earth's surface; those of military Salyuts (3 and 5), between 274 and 241 km; that of Salyut 1, thought to be civil, between 277 and 251 km; all have an inclination of approximately 52 °. Two of the sections—a transfer/docking compartment and a working/living compartment—are habitable; the third is an unpressurized instrument/propulsion section. Solar arrays provide power. Salyuts 1 through 5 had one docking port; Salyuts 6 and 7, two ports. With a Soyuz transport craft docked at one end and a Progress resupply ship at the other, the total length of the complex is 29 m. Onboard laboratory equipment has included a multispectral camera, materials processing furnaces, and devices for scientific, medical, and technological tests.*
- *Soyuz.*—An early model of this class of transport that was retired from Salyut operations after Soyuz 40 in 1981. This spacecraft, flown with and without cosmonauts onboard, provided a transport link for two- or three-person crews and supplies between Earth and the Salyut vehicles, or, in the case of Soyuz 22, a solo flight.**
- *Soyuz T.*—Unveiled in December 1979. The successor to Soyuz,[9] and similar to it in external shape and dimensions, Soyuz T can

*For example, the Soyuz and Salyut (1 and 4) propulsion systems were identical. Salyut 1 also used Soyuz solar panels. The propulsion unit of Molniya spacecraft was the same as that used on early lunar and interplanetary vehicles.

[6]K. P. Feoktistov and M. M. Markov, "Evolution of 'Salyut' Orbital Stations," *Zemlya i Vselennya*, September-October 1981, pp. 10-17.

[7]Nicholas L. Johnson, *Handbook of Soviet Manned Space Flight*, vol. 48, Science and Technology Series, American Astronautical Society, San Diego, Calif., 1980, p. 209. (Note that this book was published before the orbiting of Salyut 7.)

**As a rule, Soviet practice is to give a spacecraft a name appropriate to its class only if it achieves the purpose for which it was intended; craft which miscarry or are aborted receive either no name (as was the case for two that exploded in 1966) or the general appellation Cosmos. The failed Salyut 2 is the exception to this rule.

[8]Johnson, op. cit. Cosmos 382 was probably not a Salyut; it appears to have been considerably lighter and more maneuverable. Its altitude (5,000 km apogee), plane-change capability (51.6° to 55.9°), and perigee increase (from 320 km to 2,577 km) link it more probably to Cosmos 379.

*For a more detailed description of Salyut, see *Appendix A: The Soviet Salyut Space Program*.

**Soyuz carried three cosmonauts on four flights. Soyuz 4 was launched with one cosmonaut, but returned carrying two cosmonauts from Soyuz 5; Soyuz 5 was launched with three and returned with one. After three crewmen on Soyuz 11 died from depressurization during reentry on June 6, 1971, cosmonauts were required to wear pressurized suits, and crew size was limited to two.

transport as many as three people wearing pressure suits (or two people and a cargo pod) to the Salyuts.* Operating with solar panels, the craft sports advanced electronics and computers; it is more maneuverable than its predecessor, providing an automatic navigation control system that can be overridden for manual control, if desired. The orbital module of the vehicle, once its cargo has been unloaded into the station, can act as a container to hold used equipment and trash for subsequent destructive reentry.** The command module of Soyuz T is used to return the crew to Earth.

- *Progress.*—An unmanned transport of slightly over 7 tonnes, based on Soyuz design and using internal batteries rather than power derived from solar cells, it links to Salyut automatically, delivering equipment, parts, fuel, and other consumables.[10] The cargo capacity of Progress is about 2.3 tonnes of food, water, mail, film, equipment, and propellants. Oxygen regenerators for Salyut's life-support system are resupplied, along with gaseous nitrogen, if needed.[11] Salyut cosmonauts transfer much of this cargo into the station manually, but propellant for the station is pumped automatically. Using residual propellant, Progress spacecraft also double as space tugs, capable of pushing Salyuts into higher orbit. The last service which Progress can render to Salyut is to accept its refuse. Because it is not designed for recovery, Progress is jettisoned and destroyed upon reentry into the atmosphere.
- *Cosmos 929-Class Module.*[12]—Designed to double the habitable volume of Salyut, this module is flown without crew to the station and docked automatically. Carrying its own propulsion, guidance, and life-support systems, it is designed with several docking ports and an ejectable "sub-module" which is large enough to return the station's crew and/or heavy equipment to Earth. The first such module, Cosmos 929, was orbited July 17, 1977, and tested as a freeflyer. The next in the series, designated Cosmos 1267, docked with Salyut 6 in 1981, forming an orbital complex that flew, uninhabited, for 13 months while a variety of automated system checkouts and flight-stability experiments were carried out. The latest module of this type, Cosmos 1443 (which may weigh as much as 20 tonnes), docked with Salyut 7 in March 1983.[13] *

*Soyuz T-3, T-6, T-7, and T-8 had crews of three.

**The orbital module has not been left attached to Salyut. Without propulsion and flight control, its disposal would be difficult.

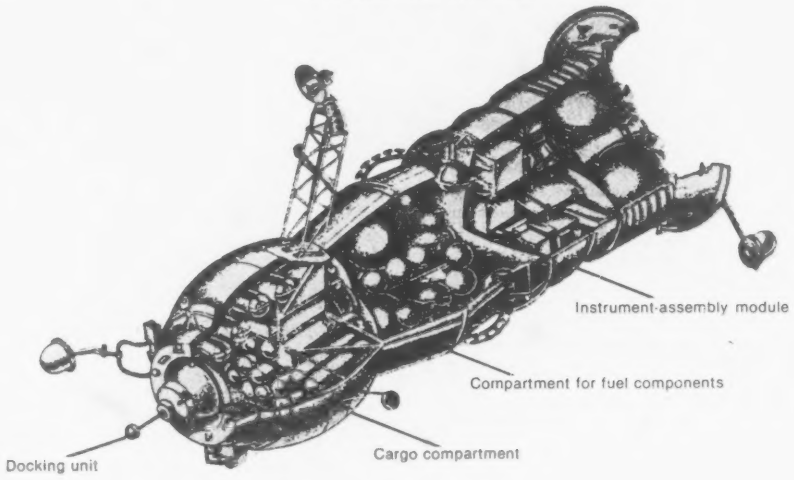
Link-up in Orbit: On June 28, 1983, the spaceship Soyuz T-9 linked up with the orbital complex Salyut T-7—"Cosmos-1443"

Progress Cargo Spaceship



Principal Characteristics

Weight	7,020kg
Weight of cargo delivered to the station	about 2,300kg
including:	
-in the cargo compartment	up to 1,300kg
-in the compartment for fuel components	up to 1,000kg
Maximum length	7.94m
Maximum diameter of pressurized compartments	2.2m
Type of booster rocket	Soyuz
Duration of flight:	
independent	up to 3 days
when docked with the orbital station	up to 30 days
Orbit parameters:	
height	200 to 350 km
inclination	51.6 degrees
rotation period	about 89 minutes

Salyut Activities

Launch dates of Salyut space stations announced by the Soviets:[14]

Salyut 1	Apr. 19, 1971
Salyut 2	Apr. 3, 1973 (failed)
Salyut 3	June 25, 1974
Salyut 4	Dec. 26, 1974
Salyut 5	June 22, 1976
Salyut 6	Sept. 29, 1977
Salyut 7	Apr. 19, 1982

Salyut 1

The first in the Salyut series carried an Orion 1 telescope for obtaining spectrograms of stars in the 2,000 to 3,000 angstrom region of the electromagnetic spectrum; a gamma-ray telescope, called Anna III, provided observations unattainable from Earth. Several optical and multispectral cameras were used for astronomical and Earth photography. Photo sessions of geological and meteorological phenomena were coordinated with aircraft flights and orbiting weather satellites. Making use of a hydroponic farm, biological experiments centered on the effects of weightlessness on plant growth and nutrition. Long-term implications of the effects of microgravity on the human organism were also studied.

A first attempt to board the station by a three-man crew on Soyuz 10 was thwarted by faulty docking equipment on the Soyuz. A second attempt by Soyuz 11 cosmonauts was successful; this three-man crew became the world's first occupants of what some would describe as a true "space station"—i.e., long-term in-space infrastructure that accommodates human beings—residing in Salyut for 23 days. This initial success, however, was followed by an unhappy ending. A valve, intended for equalizing internal and external pressures as the spacecraft descended through the atmosphere during recovery, jerked open at the instant of the explosive separation of the command and orbital modules, permitting the cabin's atmosphere to escape. The cosmonauts, wearing no spacesuits, perished.* From then until the launch of Soyuz T-3 in 1980, Soyuz vehicles were redesigned to allow the crew to wear spacesuits. Crew size was reduced to two to provide sufficient room for the suits and related equipment. Salyut 1 was intentionally removed from orbit 175 days after launch.

Salyut 2

This vehicle did not achieve stability in orbit, began to tumble, and broke up before crews could occupy it.

Salyut 3

Unlike Salyut 1, which had two sets of fixed solar panels fore and aft, Salyut 3 carried two larger panels attached just aft of the centerbody, on the rear transfer module.[15] These panels could be rotated so the craft could continue to receive solar power whenever it was in sunlight, whatever its orientation. Salyut 3 was also modified so that its docking port was aft.[16] Other noteworthy modifications included higher efficiency power and life-support systems and more convenient interior design.

Cosmonauts aboard Salyut 3 conducted some 400 scientific and technical experiments, including high-resolution photo reconnaissance and/or Earth resources observation, spectrographic study of aerosol particles in the Earth's atmosphere, the culturing of bacteria, and the recycling of water.

The crew of Soyuz 14 resided aboard Salyut 3 for 14 days, but a follow-on Soyuz 15 crew proved unable to effect docking. Overall, the station remained operational for twice its design lifetime. Some 2 months after Salyut 3's final crew departed, a data capsule was ejected and recovered on Earth. That only a few photographs,

[14]Cosmos 557, launched May 11, 1973, has been identified in Western circles as a successfully orbited Salyut, although the station suffered a propulsion or command-sequencer failure, rendering it useless for human occupation. The vehicle rapidly decayed in orbital altitude, reentering the atmosphere on May 22, 1973. See, "Reception of Radio Signals From Cosmos 557," The Kettering Group, *Spaceflight*, vol. 16, 1974, pp. 39-40.

*The cause of death was embolism, i.e., the formation of bubbles in the bloodstream.

[15]Although all subsequent Salyuts retained this midship mounting of solar panels, they were placed farther aft on Salyuts 3 and 5 than on Salyuts 4, 6, and 7. See, for example, *AW&ST*, Dec. 4, 1978, p. 17.

Soyuz 11/Salyut 1. Total volume: 100.3 m³. Total weight: 25,600 kg. Total solar panel surface area: 42m²

showing noncritical interior equipment aboard Salyut 3, have been released encourages speculation that its primary mission was probably military.

Salyut 4

The design of this station, seemingly primarily civilian in character, allowed the crew more ready access for repair and replacement purposes. Two navigation systems for the station's automatic control were evaluated, as was a new teletype system. Onboard scientific equipment, weighing about 2.5 tonnes, was of much greater variety and capability than that carried on previous stations. The cosmonauts' time was devoted each day to a specific area of investigation—astronomical, Earth resources, or biomedical. X-ray, solar, and infrared spectrometric telescopes were among the host of instruments employed. Making repeated observations of agricultural patterns, forests, and maritime areas, the crew collected a large body of data on Earth resources. They also studied micro-organisms, higher plants, and the human cardiovascular system, measuring the tone of blood vessels and the circulation of blood to the

Soyuz 18/Salyut 4: Total volume: 100.3 m³. Total weight: 25,600 kg. Total solar panel surface area: 60 m². Solar panel span: 17 m

brain. The cosmonauts also evaluated the effectiveness of various exercise and diet regimes for counteracting the deconditioning effects of microgravity.

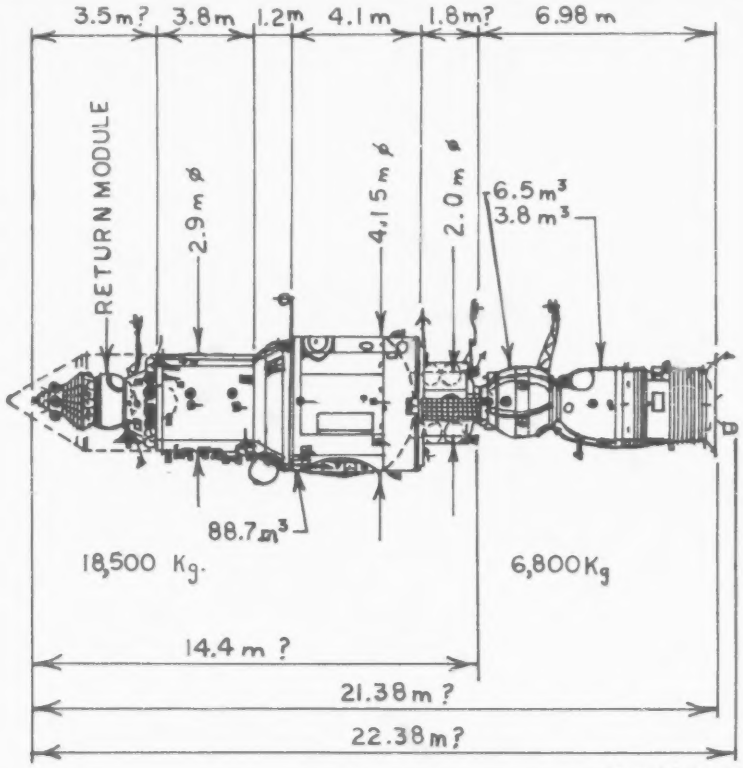
The first crew to board Salyut 4 arrived on Soyuz 17; they remained for 29 days. The mission of their scheduled successors, the crew of Soyuz 18A,[17] was aborted during ascent. Next aboard were the Soyuz 18B team; they remained on the station for 62 days. Soyuz 20, a vehicle without crew, carried biological specimens; it docked and remained at the station for 89 days before returning to Earth. Part of its mission was to determine whether Soyuz could remain without power for a relatively long time before restarting its power supply without mishap—an important consideration in planning for one crew to remain aboard a Salyut for a lengthy mission. Salyut 4 was purposely taken out of orbit after 770 days of flight.

[17] 18A is the U.S. designation. The Soviets refer to this event as the April 5 anomaly.

Salyut 5

Salyut 5, the second station thought by Western analysts to be primarily military, was the last in the Salyut series to carry only one docking port, a design characteristic which effectively prevents a resupply vehicle from docking when a crew of cosmonauts is already aboard.* Salyut 5 demonstrated a high-resolution camera, similar to that on Salyut 3, that was used to study mineral deposits, seismic areas, environmental damage caused by mud streams and railway construction paths. A device for smelting certain metals—bismuth, tin, lead, and cadmium—and a crystal growth experiment were evaluated in the station's microgravity environment. As in previous Salyuts, biological experiments on fish, plants, and fruit flies were also conducted; algae and higher order plants were cultivated to examine the effects of the spaceflight environment on their development and growth.

*It is technically possible, but too risky, to back off one spacecraft and then dock another while the crew is on board the station.



Credit: ©C. P. Vick, 1983

"Military" Salyut Conceptional Design: Total volume: 99 m³. Total mass: 25,300 kg. Total solar panel surface area (estimated): over 50 m². Total mass: over 25,000 to 25,300 kg. Only a few written descriptions, a few movie film segments, and a few photographs of the internal and external design layout of the Military Salyut 3 and 5 vehicles have been released

Over the course of Salyut 5's stay in orbit, Soyuz 21 brought a two-man crew, who remained on the station for 49 days; the crew of Soyuz 23 failed to dock; and the crew of Soyuz 24 remained aboard for 16 days.

Like Salyut 3, this station ejected a recoverable pod to Earth after its last crew departed, and, as with Salyut 3, the Soviets have released only internal photographs of limited interest. The station remained in orbit for 412 days before it was commanded to reenter.

Salyut 6

By far the most productive of Soviet space stations, this "second generation" Salyut included two docking ports, fore and aft; the station was fashioned to support a new propulsion system capable of being refueled in orbit. A water-regeneration device became a standard feature of the life-support system, supplying crewmembers with wash water; fresh drinking water was stored. Many of the experimental systems tested on earlier stations became operational on Salyut 6. A new multispectral camera (which had been flight-tested on Soyuz 22) and astronomical telescopes were flown. During its mission, cosmonauts assembled and deployed from Salyut's aft end a dish antenna used in mapping radio emissions from the Sun and the Milky Way, although the ultimate success of this experiment is in doubt.[18] Several materials processing furnaces were appraised, and infrared-sensitive semiconductors were produced. Other experiments produced superconductors, eutectics, alloys, pure metals, glass, ionic crystals, and metal oxides.[19] Salyut 6 cosmonauts also tested newly designed extravehicular spacesuits.

Cosmonauts routinely worked as in-orbit repairmen, enabling the station's design life of 18 months to be greatly surpassed. Because of the longevity of Salyut 6, perhaps to the surprise even of the Soviets themselves, its crews registered an impressive list of accomplishments. Space applications and Earth observations each accounted for about one-third of the cosmonauts' work schedule; the final third was split between biomedical studies and astrophysics.

The two docking ports permitted 33 successful dockings using vehicles with and without cosmonauts. At least two crews tried but failed to dock with the station. Five long-duration cosmonaut crews and 11 visiting crews accumulated a total of 676 days of operation. New duration records for human spaceflight were successively established: 96, 140, 175, and 185 days. During Salyut 6's lifetime, eight cosmonauts from the Soviet bloc resided in Salyut for short periods; Soyuz 33, carrying a non-Soviet crewmember, along with a Soviet pilot, failed to dock.* Salyut 6 operations introduced the use of Soyuz T and Progress vehicles, multiple-crew dockings, refueling in orbit, and the Cosmos 1267 module.**

Cosmos 1267 docked with Salyut 6 in June 1981 for a long series of what were described as checkouts of automated systems and "dynamic tests" of the overall response of the structure to maneuvers while docked with another vehicle. According to Soviet space planners, Cosmos 1267 represented a "prototype space module," built to expand the operations of future stations; such modules could be dedicated to materials processing and astronomical or other scientific pursuits, or they could be outfitted as living quarters. They could also be undocked from Salyut, flown alongside the station and reconnected. This configuration would be particularly useful for the conduct of experiments in materials processing, because it could avoid perturbations caused by the station's reactions to movements of the cosmonauts.[20]

The Soviets apparently were undecided about using their long-lived Salyut 6 for future missions,

[18]Craig Covault, "Radio Telescope Erected on Salyut 6," *AW&ST*, Aug. 13, 1979, pp. 54-55. See also "Soviets Ready Salyut 6 Crew Return," *AW&ST*, Aug. 13, 1979, p. 21.

[19]James C. Brown, *Materials Processing on the Soviet Salyut 6 Space Station*, Memorandum SWM81-10041, Central Intelligence Agency, National Foreign Assessment Center, Apr. 1, 1981. Soviet research in the materials processing-in-space arena appears extensive. According to MIT professor Harry Gatos, before a House space subcommittee review of space processing, a large new Soviet research institute employs several hundred full-time scientists working on space materials processing. Other countries involved in this institute include Poland, Hungary, Czechoslovakia, and France. See *Astronautics and Aeronautics*, September 1979, p. 9.

*Soyuz 25 with two Soviet crew also failed to dock with Salyut 6.

**There was no crew aboard either Cosmos 1267 and Salyut 6 during their docking of 40 days, after which both were deorbited.

Total volume with one Soyuz and one Progress: 106.9 m³. Total volume with one Soyuz: 100.3 m³. Total solar panel surface area: 60 m². Solar panel span: 17 m

and twice had Cosmos 1267 boost the complex into a higher orbit. After Salyut 7 was launched, Cosmos 1267 propelled Salyut 6 into a destructive reentry on July 29, 1982. The stay of Salyut 6 in orbit lasted 4 years and 10 months.[21] [22]

Salyut 7

Currently, the Soviet Union is maintaining Salyut 7 in orbit. Soviet space officials indicate it is similar in size and shape to its predecessor.[23] [24] Two docking ports are again provided, one of which has been modified to handle larger spacecraft. The standard station control system on Salyut 7—the result of experiments conducted on other stations—allows its crews to operate the facility in more automatic modes.[25] Recommendations from cosmonauts who had lived aboard Salyut 6 led to an interior "modernization program" to make Salyut 7 more livable. Designers have taken special care to protect certain observation windows, shielding both inside and outside panels with removable covers, because contaminants from propulsion unit firings, as well as impacts from micrometeorites, degraded the windows on Salyut 6. The color scheme was changed to improve the residential and working environment, and a refrigerator was installed.

Salyut 6 carried a submillimeter wavelength infrared telescope; Salyut 7 contains a complex of X-ray equipment. The first long-duration crew

Crewmen on Station Aboard Salyut 7

used a new computer-controlled 300-lb materials-processing furnace to produce several pounds of semiconductor monocrystals. This furnace operates automatically when the station is unoccupied. New systems for medical examination and diagnosis have improved the range of biomedical parameters that can be monitored, either onboard by the cosmonauts or remotely from the ground. For example, a thorough electrocardiogram can be obtained automatically. Measurements of blood circulation in the cerebral cortex, an important parameter in near-weightless conditions, are receiving particular attention.

Performing about 300 experiments, the station's first long-term crew worked to meet orders from 500 national economic and scientific centers. Soviet officials stated that, for the first time, a Salyut space station undertook "direct research production tasks."[26] Some 20,000 photographs of the Earth's surface were reportedly taken during the first phase of this operation.

Initial operations of Salyut 7 relied on Progress vehicles for resupply and refueling.[27] The Soyuz T-5 transported a crew of two to the Salyut in May 1982. Subsequently, a Soyuz T-6 with three aboard, including a French spationaut, and a Soyuz T-7 with three, including the world's second woman cosmonaut, visited the primary crew on separate occasions. The primary crew set a new world endurance record for spaceflight: 211 days.

On March 2, 1983, "a modular transport ship," Cosmos 1443 (a Cosmos 929-class module), was launched, and docked with Salyut 7 on March 10 in a configuration similar to the Salyut-6/Cosmos-1267 complex.[28] Although a Soyuz craft with a crew of three aboard failed to dock with the complex in April 1983,[29] a two-person crew boarded the station on June 28, 1983, and remain aboard as of this writing.

Members of the Soyuz-9 space mission

The Salyut-7/Cosmos-1443 orbital complex was thought capable of housing as many as six crewmembers.* Stationing of that many people aboard the complex would have born out earlier Soviet pronouncements that this configuration was a prototype for future larger scale space stations. On August 14, 1983, Cosmos 1443, along with its descent module (with a capacity for returning one-half tonne of cargo, but not a crew member) was undocked from Salyut 7.** Then on September 19, 1983, Cosmos 1443 was inten-

[26] "Kuznetsov Presents Awards to Salyut 7 Cosmonauts," Moscow Domestic Service, LD291458, Dec. 29, 1982.

[27] In the early phase of Salyut 7, two small "subsatellites" were launched from the station by its first long-duration crew. These satellites, Iskra 2 and Iskra 3, were constructed by students of a Moscow Aviation Institute and served as communications satellites for amateur radio enthusiasts. The two satellites were "launched" from the station's airlock. For a detailed account of early work on Salyut 7, see: "Salyut Mission Report," by Neville Kidger, *Spaceflight*, January 1983, pp. 28-29.

[28] "Soviets Launch Module to Enlarge Salyut 7," *AW&ST*, Mar. 7, 1983, p. 19.

[29] "Soviet Docking in Space Fails; Mission Aborted," *Washington Post*, Apr. 24, 1983, pp. A-1, A-12.

*It is not clear that docking arrangements allow more than one Soyuz T to dock with a Salyut 7/Cosmos 1443-type combination at a time; such a provision would be expected in the future.

**A rather complex sequence of events occurred during August 1983. Cosmos 1443 undocked on August 14. Then on August 16, Soyuz T-9 undocked, the Salyut was rotated through 180°, and the

The crew of the Soyuz T-7 spaceship (from left to right)—crew commander Leonid Popov, Pilot-Cosmonaut of the U.S.S.R.; researcher engineer Svetlana Savitskaya; and flight engineer Novosti

tionally deorbited, perhaps because of a serious malfunction affecting its operation.[30] More recently, Salyut 7 itself has experienced a serious propellant leak, leaving it with two of its three oxidizer tanks empty and 16 of its 32 attitude control thrusters unusable. Because of the difficulty of making repairs, it is less likely that Salyut 7 will become a major component of a large modular station.

Military Utility of Salyut

Salyut space stations serve both military and civilian needs.[31] Through the mid-1970's, each station could be distinguished as military or civilian by its design, communications frequencies, orbits, onboard equipment, and crew composition. Such distinctions are virtually impossible to draw for the Salyut 6 and 7 stations. Indeed, now that 6 years have passed since the last Salyut clearly identifiable as military was used, a separate military Salyut program may no longer exist.

Civilian Salyuts (1 and 4) were flown in higher orbits, increasing their value for astronomical observations. Telemetry was typical of Soviet nonmilitary spacecraft, and the crew commander, although usually from the Soviet military, was accompanied by a civilian flight engineer.

In contrast, military Salyuts (3 and 5) were flown in lower orbits, presumably to get the most out of the capabilities of onboard photo reconnaissance assets and activities which replaced the astronomical activities of civilian flights.* Flights of these Salyuts, typically using radio frequencies

Soyuz was redocked at the "front" end of the station. On August 17, Progress 17, bringing additional fuel, air, and water was docked to the "back" end of the station. On August 19, the descent module from Cosmos 1443 landed in Kazakhstan, U.S.S.R. Since the undocking of Cosmos 1443 and Salyut 7, the two spacecraft went out of and (through firing of th.; motor of the Progress attached to Salyut) came back into orbital phase, but apparently no attempt was made to redock prior to the intentional deorbiting of Cosmos 1443.

Cosmos 1443/Salyut 7/Soyuz T: Total mass: about 47,000 kg. Total solar panel surface area: 100 m². Total power output: 7 kW. Total volume: 150.3 m³. Solar panel span: 16-17 m

associated with other Soviet military space missions, were conducted by all-military crews. They remained in orbit for shorter periods than their civilian counterparts and ejected capsules for recovery on Earth.

Of course, there must be some military interest in scientific programs. For instance, astronomical investigations completed by Salyut crews maintained the orientation of certain equipment to an accuracy of a few arc-seconds, a capability related to what might be needed to aim directed-energy weaponry. The materials processed in microgravity could range from electronic components to new pharmaceuticals.

Many activities aboard Salyut might be described, in the United States, as civil, but others might well have military implications. Whether military activities aboard these stations pose a serious, near-term threat to the United States cannot be determined from the open literature. Certain military operations may have been turned over to automated spacecraft: Soviet advancements in satellite photo reconnaissance may have reduced the need for crewmembers to gather these data.

Comparisons with the U.S. program are also complicated by the fact that no operational requirements for U.S. military missions aboard a space station, particularly those requiring crewmembers, have been formally stated.[32] However, in view of President Reagan's speech in March, 1983, on the subject of defense against ballistic missiles, this assessment may be changing.[33] In any case, the military value of the Soviet space station remains open to question.

Capability Base for Salyut Program

The Soviet technology base must inevitably affect its space program. A thorough appraisal of this base cannot be obtained because the Soviets tightly control what information about the program is made public. Observers, however, have noted these characteristics:[34]

- *Simplicity.*—Compared with similar Western systems, Soviet components are, in general, relatively less complicated.
- *Commonality.*—Once a basic system or subsystem is developed, it is used as much as possible thereafter. With this approach, a relatively narrow technological base can serve much broader needs.
- *Gradual Change.*—This principle derives from the other two. Because each system is closely related to its predecessor, the risks attendant on innovation are reduced.

In sum, the Soviets prefer to use a single, reliable basic design over a relatively long time in order to provide several generations of systems for similar or related uses.

Professional surveys of industrial technology in the U.S.S.R. suggest that the Soviets are generally unwilling or unable to undertake rapid innovation. In some cases, however, a few critical suppliers and supporting industries have been able to set priorities that led to rapid change.

---

[32] At the Space Station Symposium held in Washington, D.C., in July 1983, Richard DeLauer, Undersecretary of Defense for Research and Engineering, reiterated this position. For an earlier discussion, see: Joel Levy, et al., "Potential Military Applications of Space Platforms and Space Stations," *Eascon 82, 15th Annual Electronics and Aerospace Systems Conference, IEEE Conference Record 82CH1828-3*, Sept. 20-22, 1982, pp. 269-276. This paper states: "It is apparent that, at this time, the DOD has not defined any firm requirements for space platforms or space stations." The military utility of a manned space station, say for photo reconnaissance, requires detailed tradeoff studies. " . . . in order to evaluate whether the increase in system performance due to man's presence warrants the increase of approximately an order of magnitude in the cost of the program. Any increase in system performance achieved by such means would be measured by some, as yet undefined, weighing of factors such as cost, risk, survivability, reliability, threat recognition and the time to respond."

[33] "President Seeks Futuristic Defense Against Missiles," *Washington Post*, Mar. 24, 1983, pp. A-1, A-13. See also, "Reagan Plans New ABM Effort," *Science*, vol. 220, Apr. 8, 1983. More recently, the Defensive Technologies Study Team, headed by former NASA Administrator James C. Fletcher, has been reported as concluding that "a space-based [ballistic missile defense] system may also require a continuous manned space presence . . . Both cost and effectiveness may justify manned systems . . . Development of a repair and refurbishment system may be the key to operational and economic viability of space-based ballistic missile defense." *AW&ST*, Oct. 24, 1983, p. 50.

[34] Herbert P. Ely, "Impact of the Technology Base on Soviet Weapon Development," *Army Research, Development & Acquisition Magazine*, May-June 1982, pp. 12-13. For a broader look at conditions of Soviet technology see: *Industrial Innovation in the Soviet Union*, Ronald Amann and Julian Cooper (New Haven, Conn.: Yale University Press, 1982). The authors discuss Soviet military technologies in detail, and conclude that they do not have the quality and level of sophistication that those of the United States have. In general, although Soviet industry is slow to respond to new R&D initiatives, the technology lag is smallest in the defense and space sectors.

Hampered by a lack of precise instrumentation and sophisticated engineering techniques, Soviet space designers frequently take a "brute-force" approach to problem-solving.[35] Although this approach has obvious drawbacks, it does tend to impose—in contrast to the U.S. system of single-unit production—an economy of operation through the exploitation of continuing production of less complex hardware. Lastly, there is a consensus that an uneven research and development base, poor quality control, and poor quality assurance has impeded Soviet space development on many fronts.[36]

Evidence for these evaluations is provided by the mixed results from lunar probes and interplanetary exploration. Crossing the relatively short distance to Earth's neighboring Moon, Soviet vehicles were generally successful in achieving soft landings, trekking across the lunar terrain, and returning samples of the Moon's surface directly back to Earth. Four-month dashes to the planet Venus resulted in significant Soviet success in landing vehicles and operating their sensors for brief periods on the surface of that extraordinarily inhospitable world.

By contrast, 9-month journeys to Mars have met with repeated failure, and no attempts have been made to probe Mercury, Jupiter, and Saturn. The outer planets in particular, the subject of intense scrutiny by U.S. space vehicles, have so far remained beyond the reach of Soviet probes. The rather limited time during which important systems aboard Soviet spacecraft remain operational is still a major limitation. This weakness also appears in spaceflights with Soviet crews, who have been able to keep Salyuts operational by undertaking unscheduled maintenance and repair.

As these operations of Soviet spacecraft are reviewed, certain limitations become apparent:

Salyut.—Although Salyut is smaller than currently proposed U.S. concepts, it has accommodated Soviet crews for as long as 211 days. Attachment of a Cosmos 929-type module should markedly improve living conditions.

Salyut cannot communicate via line-of-sight circuits directly with Earth stations (in the Soviet Union) during every one of its 15 or 16 daily orbits. On those orbits when communication is not possible, the cosmonauts sleep, and telemetry, communicated *via* shortwave circuits, is sometimes used to monitor basic onboard systems. Even during the in-contact orbits, the crew can communicate with Earth stations on Soviet territory for only 25 minutes out of every 90.

Compared with scientific equipment proposed for any future U.S. "stations," Soviet scientific equipment is low in weight and used sporadically: just a small portion of it is replaceable. The station itself can generate 4 kW of power, Cosmos 1443 contributed 3 kW from its own solar panels while it was attached to Salyut, and additional modules may be expected to do likewise. The low return-weight of equipment transported back to Earth via Soyuz T is one constraining factor; because of the delay in returning photographic film to Earth, its use, rather than reliance on advanced electronics, for remote sensing of the Earth is another (although the installation of live television transmission equipment aboard the latest Salyut has partially overcome this limitation).* The life-support system requires regular deliveries of drinking water and supplies for purifying the cabin atmosphere.** The current configuration requires that Salyut be refueled through its aft docking port.[37]

Soyuz T.—This vehicle, like the original Soyuz, is a reliable, though relatively unsophisticated, spacecraft. Its onboard computer has no backup. The latest mission of cosmonauts aboard Salyut 7 demonstrated an operational lifetime of Soyuz T, while attached to the station, of 150 days. Be-

Browne, "Soviet Science Assessed as Flawed But Powerful," *The New York Times*, May 20, 1980, p. C-3, which describes the buildup of the Soviet science work force and its potential for scientific surprise.

*App. A.

**Some water is recycled aboard Salyut, a capability that U.S. spacecraft do not possess.

[37]For a discussion of rendezvous and docking techniques involving Soyuz T and the Salyut stations, see: *Aviatsiya i Kosmonautika*, 1979, pp. 36-39, translated in JPRS 74805 Space No. 1, Dec. 20, 1979.

cause the Soviets are reluctant to land Soyuz T in the water or at night, they impose strict constraints on the duration and scheduling of its flights. Yet, they have repeatedly demonstrated the ability to deviate from these conditions when necessary. No spacecraft, of course, can land without restrictions. Indeed, the U.S. Space Shuttle Orbiter operates with even greater restrictions than Soyuz. Major modifications of the U.S. craft would be required if its staytime in orbit were to approach that of Soyuz T.

General

In order to minimize one of these deficiencies, the Soviet Union, according to a plan lodged with the International Frequency Registration Board in 1981, intends to operate a system called the Eastern Satellite Data Relay Network (ESDRN), which will employ radiofrequencies similar to the U.S. Tracking and Data Relay Satellite System (TDRSS). The Soviet system would allow reliable, nearly continuous communication with Salyut stations and other spacecraft in low-Earth orbit, commencing perhaps as early as December 1985.

Despite the fact that the Soviet technology base advances more slowly and still remains, in most instances, less sophisticated than that of the United States, it is not suggested that these factors seriously inhibit what appears to be a continuing and expanding set of objectives for productive operations in space, made possible, in part, by people aboard Salyut-class facilities, and determined by what the Soviets consider valuable. Resupply, repair, and service functions, for example, are often performed by cosmonauts, who were a key factor in the longevity of Salyut 6. The Soviets regard the adaptability of human beings as a form of insurance that permits continuous and variegated space station operations.[38]

Whereas the U.S. program from its inception was heavily influenced by the high visibility of the Apollo program and the continuing presence of test pilots, who insisted that astronauts be "in the loop" whenever possible, the Soviet program at the outset was heavily influenced by the Institute for Automatic Control, which obviously had a different orientation. However, the same unreliability of automated equipment that has plagued the Soviets' long-duration planetary probes has made the human presence an essential element in the Salyut program. As a result, the Soviets have gone far in discovering how the attributes peculiar to human beings may be put to effective use in conducting unforeseen as well as planned activities in the course of maintaining and operating a space station.[39] Their growing fund of experience supports and in turn is supported by two related requirements of their ideology and their judgment of their national security interests: that they begin "the inevitable socialist expansion into space," and that they maintain and enhance their national prestige. These factors have resulted in what should be appreciated as the cultivation of the human presence in space.

The Soviets have claimed that people stationed in space can improve the effectiveness of Earth observations. After a period of adjustment of a few weeks, cosmonauts report both improved visual acuity and enhanced perception and differentiation of color, making it possible for them to identify land features and ocean phenomena (e.g., the presence of schools of fish) that were not expected to be visible from low-Earth orbit. These findings have been pursued in real-time aboard Salyut space stations.[40,41]

In support of the human presence, the Salyut stations have served as medical laboratories in which the occupants have completed comprehensive programs of biomedical and life-science research. Much of this data-gathering is dedicated to answering the following questions: Do long spaceflights result in unacceptable psychological effects and produce harmful physiological alterations of the human body? If so, can these effects be countered? In search of answers, the Soviets

[40] Jerry Grey, *Beachheads in Space: A Blueprint for the Future*, New York, 1983, p. 42.

[41] Personal communication from Chris Dodge, Science Policy Research Division, Congressional Research Service, Washington, D.C., *re* U.S.-U.S.S.R. Working Group on Space Biology and Medicine, meeting of November 1981, Uniformed Services University of the Health Sciences (USUHS), Bethesda, Md.

are planning in-flight missions that would entail stays up to 1 year for cosmonauts.

Special exercise and diet regimes are being employed to counter changes in cardiovascular tone and muscle systems during flight and to facilitate the subsequent readaptation to gravity. Some changes such as the loss of red blood cells have been found to be self-limiting and subsequently reversible. Others, although decreasing in rate over time, may not entirely level off. In particular, osteoporosis, the loss of calcium from bone, may pose a formidable problem in the context of flight durations of a year or more in the absence of gravity.[42] [43] Extensive ground-based studies employing simulations of weightlessness (including bed rest and water immersion) are augmenting inflight research.[44]

Medical studies of the cosmonauts, supplemented by onboard diagnostic equipment to monitor their overall health on long flights, continue to be given a high priority aboard Salyut. Certain countermeasures have been designed to maintain good health and high performance during prolonged spaceflight. The most demanding of these is exercise, which consumes an average of 2.5 hours during each day in space and involves the use of specialized gear as well as conventional exercise devices.

The Soviets have devised a comprehensive psychological support program, including the transport of letters and news to Salyut crews and frequent two-way video communication with families and research counterparts on the ground. These measures have been instituted to counter the cosmonauts' isolation and heavy workload.

One challenging goal is a closed life-support system aboard Salyut that would generate water and air and produce food, independent of external supply.[45] [46] A complete growing cycle of higher order plants has been evaluated aboard Salyut, as has control of plant diseases and use of vegetables and herbs as food for human consumption.* Creation of partially closed ecological systems may conceivably lead to completely closed systems, suitable for flights of 2 years or more. Designed in accordance with biomedical information derived from past Salyut flights, these closed systems could be implemented for eventual flight to the Moon and neighboring planets; such systems might also lead to substantial cost reductions in Earth orbit operations.

[42] Arnauld E. Nicogossian and James F. Parker, Jr., *Space Physiology and Medicine*, BioTechnology Inc., NASA Headquarters contract NASW-3469, Washington, D.C., September 1982, pp. 20-24.

[43] The Soviets themselves seem undecided about whether very long-term weightlessness will be a general problem. Cosmonaut Georgi Gretchko is quoted (in "Soviets Unveil Space Station Plans," by Peter Smolders, *New Scientist*, June 30 1983, p. 944) as saying of a possible trip to Mars: "Your heart and entire organism would have become so accustomed to living in space that you would never be able to stand life on Earth again." On the other hand, see Grey, op. cit., pp. 41-42: "One of the cosmonauts, Valery Ryumin, spent a full year in space (he served on the 175-day and 185-day flights aboard Salyut 6), and was in excellent physical condition after both flights. He walked comfortably only one day after returning to the oppressive [*sic*] gravity of Earth, and was jogging happily on the third day. After exhaustive studies of the returned cosmonauts, the Soviets' bioastronautics mentor Oleg Gazenko concluded, 'I believe that humankind can be as happy in space as on Earth.' "

Future Directions

The Soviet Union's Salyut space stations have formed the backbone of an ambitious and expansive program involving human beings in space. The ideological underpinning of Salyut is the desire to project and maintain an image of scientific, technological, and industrial world leadership in space. Overall, the Soviet approach toward implementing these goals has been one of cautious advance—a step-by-step evolution consistent with an often-stated, long-term goal of spreading Soviet influence into near-Earth space and beyond. As was the case for the U.S. Apollo program, the Soviet effort does not appear to be predicated on near-term economic benefits.

The last 5 years have witnessed a growing maturity and confidence in Soviet spaceflight planning and conduct. Present Soviet activities with Salyut are approaching the establishment of a permanent human presence in low-Earth orbit.[47] Whether or not continuous human occupancy is established soon, the Soviet Union can be expected at least to maintain and probably to expand human activities in space. The Salyut space station is anticipated to remain the central element for space operations involving people, although several new programs may augment the station's use and enhance the range of future Soviet options.

Three New Initiatives

Soviet planners appear to be looking at three new initiatives: modular space stations, heavy-lift expendable boosters, and reusable launch vehicles. President Brezhnev was apparently a strong supporter of space expenditures; President Andropov's views are not fully known.[48] Although appraisals of Soviet spending are difficult,[49] one estimate puts the overall cost of the Soyuz/Salyut program during the 1970's at nearly $40 billion (in 1980-adjusted dollars). That is approximately the cost of the entire U.S. Moon Landing program—from the first Mercury suborbital flight to the final Apollo 17 Moon landing and return.[50] Moreover, the cost to develop, launch, and maintain Salyut 6 during its nearly 5-year tour-of-duty probably exceeded $9 billion (in 1980-adjusted dollars).[51] As in the United States, the economic climate in the Soviet Union might well dictate the scope, scale, and timing of any new Soviet space initiative.

Modular Space Stations

A modular station could be composed of five to eight units, separately launched and assembled in orbit. These plans are well within current Soviet capabilities. Indeed, Soviet sources have identified Cosmos 929-class modules as prototypes:

> . . . of the kind that will be linked together to form a multi-purpose orbital station. One of the modules will be a fitted-out laboratory, others will perform purely technological duties. There will also be observatory modules and whole plants for manufacturing products in zero-g. Lounge modules will be living quarters for cosmonauts to take a rest after the heavy workload they will handle in space. . . . Each station can easily be modified by changing modules to fit changing needs of the mission . . .[52]

Within a constellation of such modules, Soviet cosmonauts could begin to live in orbit more comfortably and more productively. A modular space station could be the beginning of a usefully permanent human presence in space. Among other possibilities, the crew of a large, well-equipped station would no longer have to be limited to broadly trained cosmonauts. Technicians with particular specialties could be included in the station's complement. In any case, a large modular

[52]Dr. Feoktistov, quoted in DST-14005-022082.

station would allow human beings to achieve a more normal, leisured, and productive life in space than has hitherto been possible.

Heavy-Lift Expendable Boosters

Currently, Salyut operations are carried out using two types of launch vehicles. The "A" series booster, which provides over 400 tonnes of thrust at liftoff, is the workhorse of the Soviet launcher family.[53] Variants of this booster are used to loft Soyuz, Soyuz T, Progress, and other vehicles. This standard launch vehicle, minus its upper stage, was used to orbit Sputnik 1 into space in 1957—an indication of its reliability and longevity.[54] "D" series boosters, called "Protons," have launched Salyut space stations and Cosmos 929-class modules without cosmonauts onboard. The Proton's thrust at liftoff equals about 1,000 tonnes. There are also "C" and "F" series boosters which meet other requirements, but those of the "B" series have been phased out.

Under development, according to reports reaching the West, is a new booster in the "G" series capable of producing up to 5,000 tonnes of thrust at liftoff. Previous boosters in this series were apparently destroyed in three inaugural attempts (1969, 1971, and 1972): one exploded on the launch pad and two exploded in flight. Similar to the U.S. Saturn V, the redesigned G booster, possibly carrying cryogenic upper stages, is several years away from operational status, though test flights could occur between 1984 and 1986. A Pentagon analysis claims the booster will be capable of putting very heavy payloads into orbit (180 to 210 tonnes)—six to seven times the payload weight of the U.S. space Shuttle.[55]

Some believe the new "G" series booster will lead to the long-awaited Soviet attempt to put cosmonauts on the Moon. Others believe it will be used to orbit very large electromagnetic weapons. The new booster could also propel a 90-tonne station into orbit, to be occupied by a dozen or more crewmembers by the end of the decade. Such facilities might, in some respects, be more attractive than space stations built from smaller modules. With relatively small-sized modules, such as the Cosmos 929-class, for example, there may be as much as 30 percent redundancy of hardware for rendezvous, docking, propulsion, electrical power, structural support, and the like. In a larger station, the weight of this otherwise employed hardware could be used instead for additional instrumentation, living quarters, manufacturing facilities, and other productive equipment. All of these uses could be fulfilled by such a launcher. As an alternative to developing such a "G" series launcher, the Proton booster might be upgraded to carry cosmonauts. This choice would allow some modest improvements and avoid the risks inherent in developing a new launcher.

Reusable Vehicles

The Reusable Space Plane.—Speculation concerning a Soviet version of the U.S. Dyna-Soar has been fueled by two Cosmos flight tests, each apparently designed to evaluate the aerodynamic and reentry characteristics of a winged space plane, weighing about a tonne. These missions—Cosmos 1374 on June 3, 1982, and Cosmos 1445 on March 15, 1983—flew identical trajectories; each was sent into space for a 2-hour test from the Kapustin Yar launch site near Volgograd, orbited the Earth, and landed in the Indian Ocean. A seven-ship Soviet task force supported both retrieval operations. Photographs of the Soviet recovery of Cosmos 1445, released by the Royal Australian Air Force, indicate the craft is of a lifting-body/blended-wing design.[56] Some Western experts contend that the recovered vehicles are prototypes designed to provide reentry data for a larger 10- to 20-tonne version which would carry a crew. (By contrast, the U.S. space Shuttle weighs approximately 100 tonnes.) The Soviet tests have been likened to the U.S. Asset program of the early 1960's, which made use of several

Recovery of Cosmos-1445 by the SSVRS 201 YAMAL is believed to be a quarter-scale testbed version of the Soviet space plane

gliders on suborbital flights into the Atlantic, to gather heating and structural load information on winged space vehicle designs.

Some Western observers believe this program may have begun as early as 1976. Drop tests of the Soviet space plane from aircraft, akin to those carried out in the U.S. space Shuttle program, have been reported.

The Soviet space plane is expected to be capable of ferrying three persons between the ground and the Salyut station or other platforms in low-Earth orbit. It should be able to provide a means of rapid evacuation from the station and sufficient cross-range to allow landing at any major airport. However, its design may make little, if any, cargo space available, thus affording no solution to the Soviets' inability to return heavy payloads from space stations to Earth. Although less versatile than the U.S. Shuttle, its greater simplicity might be well-adapted to quick launch and turnaround as well as rapid response to occasional reconnaissance requirements. Operation of the vehicle may begin within 2 to 3 years.

The Reusable Heavy-Lift Shuttle.—According to an assessment by the Department of Defense, the Soviet Union is apparently building a "heavy-lift" space shuttle similar in design to the U.S. Shuttle but capable of lofting twice as much payload into orbit. As detailed in a 1983 report on Soviet military power,[57] [58] the heavy shuttle, like the U.S. Shuttle, will be a delta-winged orbiter mounted on an external tank with strap-on

[57] *Soviet Military Power*, 2d ed. (Washington, D.C.: U.S. Department of Defense, March 1983), pp. 64-69.

[58] Craig Covault, "Soviets Building Heavy Shuttle," *AW&ST*, Mar. 14, 1983, pp. 255-259.

boosters. However, its ratio of payload weight to total vehicle weight is judged to be higher than that of the U.S. vehicle, and the specific impulse of its liquid-fuel strap-on boosters could be higher than the Shuttle's solid-fuel engines. In addition, the U.S. Shuttle carries 40,000 lbs of main engines and propulsion equipment on the Orbiter itself, whereas the Soviet shuttle would carry them on its main tank. This general configuration, whereby the Soviet shuttle would not have to recover its high-energy main engines, would result in a large payload bonus, though this advantage would have to be weighed against the cost of replacing the (unrecovered) engines. Overall, although its precise configuration and propellants are not known, the Soviet shuttle, with liquid strap-on boosters, could provide a payload capability of perhaps twice that of the 65,000 lbs of the U.S. Shuttle.[59]

Although the smaller space plane has been undergoing tests for several years, the heavy-lift shuttle design is relatively new and would require, perhaps, a decade of development and testing before it would be ready for regular use. Advanced versions of the vehicle could evolve into a two-stage, fully reusable system.[60] [61] At the Tyuratam spaceport near the Aral Sea, where Soviet cosmonauts are often launched, a large runway has been built and could be used to support operations for either type of reusable spacecraft.[62]

General Considerations

Although both types of Soviet reusable spacecraft may be realized in the relatively near future, Western experts disagree on the roles these vehicles might play with cosmonauts aboard. Some have suggested that the space plane could serve the Soviet military as a "space fighter."[63] Others think that the Soviets plan to use it as a replacement for Soyuz T vehicles. The heavy-lift shuttle, on the other hand, could well have an important role in boosting a new and larger generation of space-station modules into orbit.

The Soviets have bitterly criticized the U.S. space Shuttle as evidence of the "militarization of space" despite the official U.S. position that the craft is not a weapon. Soviet criticism may arise from a genuine fear of its use for military operations, or it may be a smoke screen to be maintained only until the Soviet Union can unveil a similar vehicle.[64] Soviet protests against U.S. military reconnaissance satellites, for instance, subsided once the U.S.S.R. had launched comparable spacecraft.

[59]See Picard, op. cit. It should be noted, however, that previous Soviet practice has been to rely on space structures that, relative to comparable U.S. structures, are heavy. If this practice is continued in the heavy-lift shuttle, and if this vehicle does indeed rely exclusively on liquid propellants, then a payload capacity double that of the U.S. Shuttle would imply a thrust at lift-off of some 3,000 to 4,000 tonnes.

[63]"Soviet Militarization of Space," *Air Force Magazine*, March 1982, p. 42.

[64]Soviet sensitivities as to the military usefulness of the U.S. Space Shuttle and its potential for sparking Soviet "technological inferiority" are evidenced in: *Soviet Elites—World View and Perceptions of the U.S.*, by G. Guroff and Steven Grant, Office of Research, International Communications Agency, R-18-81, Sept. 29, 1981, p. 17. Report observes:

> The U.S. space shuttle, in particular, seems to have left Soviets, including some at the highest levels, almost speechless. When they saw on television (private showings) what the U.S. had done, it was clear to many that their erstwhile "lead" in the manned space race had disappeared, and that their own program was years behind that of the U.S. Given the wide publicity of Soviet space efforts, many Soviets felt until then that the U.S. had all but abandoned space to the Soviet Union.
>
> Many believe that they are incapable of doing what the U.S. has done with the shuttle. This feeling translates for most Soviets into the further belief that if the U.S. wants to, it can change the military balance in its favor almost overnight—that it can pull some weapon/rabbit out of its technological hat at any moment and leave the Soviet Union far behind in the arms race.

Soviet concern regarding U.S. intentions to develop a space weapons capability could be amply fueled by such documents as: *High Frontier—A New National Strategy*, a Project of the Heritage Foundation, Washington, D.C. 1982, which calls for, among other elements, a military "high performance spaceplane" for inspecting or retrieval of "suspect" space objects.

American perceptions of the Soviet military presence in space is typified by: "Twenty-five Years After Sputnik—The New Soviet Arms Buildup in Space," *The New York Time Magazine*, Oct. 3, 1982, pp. 30-34, 89, 92-93, 98, 100.

Impact on Foreign Policy

The Soviet Union's space program is intended to demonstrate, inter alia, what can be achieved under its form of government. To this end, the Soviets have made political capital out of their guest cosmonaut program: a number of cosmonauts from Soviet-bloc countries—Czechoslovakia, Poland, East Germany, Bulgaria, Hungary, Vietnam, Cuba, Mongolia, and Romania[65]—were ferried to Salyut 6 for short-duration working visits. A French spationaut was transported to and from Salyut 7. Preparations are underway to include a crewmember from India in early 1984, and other countries may be invited to participate in future missions. How valuable is the guest program? At a minimum, it supports Soviet propaganda aims, and the scientific exchange, particularly with the French, may be of significant value. In any case, the Soviets clearly believe that the program is worth the relatively small investment required.

These international activities suggest the Soviets have decided to make their space program somewhat more open. Recently, they have also begun to announce some launch dates and to allow outsiders to observe payload processing, to view launches, and to access scientific data more quickly.

In contrast to the United States, the Soviet Union, in the view of some, is much more aggressive in deploying its space program as an important element in its foreign policy. Increasing openness may be the forerunner of greater cooperative efforts, particularly in the use of more instrumentation from Eastern European sources. The cooperative Soviet-French venture to probe Venus and Halley's Comet, for example, will incorporate more sophisticated technology than the Soviets have previously used, thus increasing its chance of success.[66]

Whereas the Apollo-Soyuz Test Project (ASTP) came to fruition as a product of detente, similar joint U.S.-Soviet ventures involving space stations are viewed by many as out of step with current political realities. Others suggest that such ventures are technically logical and diplomatically feasible.[67] There is also a possibility that cooperative space ventures could become polarized: the Soviet Union might increase its working relationships with Eastern European countries and, perhaps, France, while the United States works with Japan, Canada, and Western Europe.[68] Future Salyuts could incorporate "internationalized" modules dedicated to specific scientific research or commercial application.

The impact of an evolving Soviet space station program on U.S. space policy is unclear. Many observers agree that a U.S.S.R. pronouncement that a "permanent presence in space" had been achieved would do little to reshape U.S. civilian space objectives. Even bolder announcements of Soviet intentions to send human beings to the Moon or to traverse interplanetary distances to establish a human presence on Mars, might have little influence on U.S. pursuits. Creation of a significant and obvious military installation in orbit, however, might well dictate an American response in kind.

In the end, a U.S. response to any new Soviet space project would be heavily influenced by public opinion and the circumstances of that moment. It is impossible to predict with much assurance just what Soviet activities might trigger an important American reaction.

Conclusion

In any characterization of the future of the Soviet space program, caution is the rule. Western forecasters during the past 5 years expected a more dynamic effort than the Soviets actually put forth. Still, the Soviets have shown considerable perseverance, and their predictions about even bigger space stations—capable of housing "large collectives" rather than small crews—should be taken seriously. Modularized space facilities—carrying equipment for astronomical, physical, and chemical experiments, and for technology development purposes, adapted for multidisciplinary programs for both civilian and military purposes—can be expected.[69] It is possible that useful and marketable products and services could be provided. Such stations, situated in various orbits, would be a straightforward extension of demonstrated Soviet capabilities. Eventually, these same facilities could involve international teams.

With a sufficient commitment of resources, the Soviets may be able to maintain a continued human presence in space through the use of heavy-lift launchers and/or expanded use of currently available boosters. A shuttle-type vehicle would permit routine access to platforms in near-Earth orbit. A large Salyut complex could serve as a space transportation node or base camp.

As recently as late November 1983, the Soviet newspaper *Pravda* asserted that the main thrust of Soviet cosmonautics is "the creation of [sophisticated] orbital manned complexes, which can be improved during lengthy use and be reconstructed depending on the nature of the tasks being tackled."[70] The next step in the Soviet space program will aparently be "the transition from long-term orbital stations regularly visited by replacement crews to a multi-team, permanently manned orbital complex."[71]

From a permanent foothold in near-Earth orbit, the next step might be an extension to geostationary orbit. Soviet scientists have argued that a series of orbital stations might one day stretch for hundreds of miles in a given orbit.[72]

Salyut operations are one step in the Soviet drive toward mastery of space. It is quite conceivable that, by the end of the century, they cound put cosmonauts on the Moon.[73]

[70]Quotation from *Pravda*, Nov. 25, 1983, appearing in *Aerospace Daily*, Dec. 1, 1983, p. 155.

[71]*Pravda*, Nov. 28, 1983, quoted in *Aerospace Daily*, Dec. 1, 1983, p. 155. The article continued as follows: "*Pravda* said the size of such a complex will be impressive even by the standards of construction on Earth. For instance, the parabolic antenna alone should have an effective aperture . . . [o]n the order of 300-350 meters. In addition, it must be geared to a long period of operation—15-20 years as a minimum.

"*Pravda* said that '[t]oday, this complex is conceived as a unified system of large-scale installations in orbit at an altitude of 200-400 kilometers, linked to Earth by freight and passenger transport spacecraft. The complex will include specialized scientific research laboratories, comfortable housing modules, powerful energy installations, a refueling station, repair workshops, and even construction sites for producing and installing standardized construction components. The real potential of orbital flight for the *ad hoc* solution of urgent national economic tasks will also be expanded many times over.'"

[73]"The Soviets think that in about 20 years a journey to Mars may be possible. By this time, spaceships may incorporate centrifuges that simulate the conditions of living under gravity." Smolders, op. cit., p. 944.

Postscript

According to accounts published in U.S. newspapers on October 12, 1983,[74] the Soviets announced a nearly disastrous setback when an A-2 rocket, bearing a Soyuz T and two cosmonauts, exploded on a launch pad at the Tyuratam cosmodrome. Apparently, just prior to scheduled liftoff, a fire was detected at the base of the launch vehicle, and the launch escape system was triggered, either by automatic failure detection circuitry, the blockhouse crew, or the cosmonauts themselves. The launch escape tower rocket ejected the Soyuz orbital module and the descent module carrying the cosmonauts moments before the booster exploded beneath them. Subsequently, the descent module was separated from the orbital module and parachuted to Earth. The escape rocket subjected the cosmonauts to a high velocity, high G, escape trajectory, and the landing impact velocity was substantially higher than the normal 3.3 feet per second. Both may have sustained some injuries. This two-man crew was to have made a week-long resupply visit to the two cosmonauts who have been aboard Salyut 7 since June 28, 1983.[75]

This accident did not seem to have placed the crew aboard the Salyut in any great danger because they were resupplied by Progress 17 in mid-August and Progress 18 in October and because they were resupplied by Progress 17 in mid-August and Progress 18 in October and because their Soyuz T-9 was still capable of returning them to Earth. In addition, the Soviets have at least three other (undamaged) launch pads at Tyuratam, and almost certainly have another Soyuz T and an A-2 booster which could have been integrated and readied for launch on short notice. The degraded condition of Salyut 7, however, adds additional uncertainty for future missions. The Soviets have announced that the most recent crew of cosmonauts returned to Earth on November 23, 1983, after a mission of 150 days.

Coincidentally, NASA has had to postpone the first flight of Spacelab aboard the Shuttle because "a liner that protects the lowest part of one of the [reusable] solid-rocket engines from heat" was almost burned through during the previous Shuttle flight.[76] If the flame had burned through part of the engine in flight, the Shuttle would have become aerodynamically unstable some 2 minutes after launch; the result could have been a catastrophe.

The U.S.S.R. accident and the U.S. near-accident indisputably show that space operations are still hazardous, even with systems that have been flight-proved time after time.

Material provided to OTA by Dr. Balayan, Vice Chairman of the Intercosmos Council of the U.S.S.R. Academy of Sciences.

The Salyut Orbital Scientific Station

The creation of the Salyut orbital stations is an important stage in the development of Soviet cosmonautics, intended to increase the length of both manned and unmanned flights.

The total mass of the orbiting scientific complex, including two transport ships, is 32,500 kilograms (kg); the mass of the space station in orbit is 18,900 kg, the mass of the transport ship in orbit is 6,800 kg.* The dimensions are as follows: 1) total length docked with two transport ships 29 meters (m), 2) station length 15 m, 3) maximum station diameter 4.15 m, and 4) maximum transverse station dimension with solar panels open 17 m.

More than 20 portholes are provided for the conduct of scientific experiments, visual observation, and still and motion picture photography from the compartments of the station.

Hatches in the docking units are used to allow the crew to move between the transport ship and the station. After docking, the crew can work and rest both in the compartments of the station and in the transport ships, moving through these hatches.

Terrestrial conditions are maintained in the sections of the station in orbit—the same gas composition, atmospheric temperature and pressure, providing the necessary conditions for the cosmonauts' activities.

Composition and Arrangement of Orbital Station

The station consists of five compartments: transit, operations, scientific apparatus, intermediate, and equipment compartments.

During powered flight the external elements of the transit section and parts of the small-diameter operations section are protected from aerodynamic forces by fairings which are later jettisoned.

The scientific equipment installed in the scientific apparatus section is protected during powered flight by a scientific apparatus cover which is also jettisoned after orbital insertion.

The transit section is bounded by conical and cylindrical (2 m diameter) sealed envelopes.

The passive portion of the docking unit—the "cone"—is installed at the conical end of the section (the active "rod" docking unit is installed on the spacecraft), while the cylindrical portion of the section adjoins the operations section of the orbital unit.

There is a hatch in the conical envelope of the transit section to allow servicing of the station on Earth and to allow the crew to exit into space. The outer surface of the transit section carries:

- antenna of the approach and docking unit;
- optical lamps for orientation during manual docking of spacecraft;
- external television cameras;
- panels with temperature regulation units;
- gas storage cylinders of the life-support system containing air;
- ionic and solar sensors of the station's orientation system;
- handles and restrainers for cosmonauts in spacesuits performing space walks; and
- panels for the study of micrometeorites, contamination of optical surfaces, and properties of rubber and biologic polymers.

The outside of the transit section and the apparatus installed on it are covered with a vacuum-shield thermal insulation to maintain the required temperature conditions.

Within the transit section, which is used as a lock, are spacesuits, panels, equipment and attachment devices to support space walks.

There are seven portholes in the transit section. Some carry instruments for astro-orientation of the station. These instruments, together with the corresponding control panels and knobs which control the orientation of the station, form two control posts (post Nos. 5 and 6).

*These masses appear to be related to Salyut 6 and Soyuz craft.

The transit section connects to the operations section of the station through a sealed airtight hatch. The operations sections consists of two cylindrical shells (2.9 m diameter and 3.5 m length, and 4.1 m diameter and 2.7 m length) connected by a conical section (1.2 m in length).

The cylindrical shells have spherical ends. The posterior end has a hatch which connects the operations sections with the intermediate chamber.

In the operations section, equipment is arranged along the section forming a common passageway beside the equipment, with instruments and equipment located to the left and right. The instruments and equipment are installed on standard racks which form the frame of the interior.

Most of the monitoring and control systems and scientific apparatus of the station are in the operations section. The apparatus with which the station crew works directly is grouped by functional purpose in five control posts (there are two additional control posts in the transit section, as was mentioned earlier).

Post No. 1 is the central control post of the station, where control of the main station systems is concentrated. It is located in the lower portion of the operations section (in the small diameter area). This post has two working locations equipped with chairs (for restraint), communications equipment, control panels, a lever to control the angular position of the station in space, optical sites of the orientation system, and portholes with no equipment.

To the left and right of the control panel are the regenerator cartridges of the station's gas-mixture support system, as well as the refrigeration and drying units of the temperature control system. Near the forward end of the operations section beyond control panel No. 1 are the gyroscopic instruments of the orientation and motion control system, mounted on a rigid frame.

Post No. 2 (the astropost) is also in the lower, small diameter portion of the operations section, closer to its conical portion. This post is used for astro-orientation and astro-navigation of the station. The post is equipped with communications equipment, an orientation control panel, and astro-instruments (installed on two portholes).

Between post Nos. 1 and 2 in the small diameter end of the operations section is the area where the crew eat and rest. In this area is a table with special devices for heating food. A drinking water container is attached to the table. Along the right side in this area is the system which regenerates water from atmospheric moisture condensate. The cosmonauts obtain hot and cold water from this system. Behind the interior panels on the left side is the onboard computer apparatus. The cosmonauts can perform minor preventive repair of equipment on the table in this area, for which they have a special onboard toolkit available.

Post No. 3 is intended to control the apparatus located in the scientific equipment section. This post is located in the large diameter portion of the operations section in its lower part near the rear end. Control panels, communications equipment, and retainers are installed here.

The instrument zone contains the onboard radio system, radio telemetry system, and power supply system control apparatus. Near the aft end of the operations section on the left and right sides are the crew's bunks, and in the instrument area there are food storage containers.

In the upper portion of the operations section (near the aft end) are two locks for jettisoning the crew's wastes into space. Wastes are collected in special containers and, after they are ejected from the lock chamber, burn up in the atmosphere.

On the aft end of the operations section is the head. It is separated from the remaining portion of the operations section and has forced ventilation. Beside it is a vacuum cleaner, dust filters, storage for water, linens, and other life-support system consumables.

In the forward, larger-diameter portion of the operations section is a system allowing the crew to shower periodically.

Post No. 4 is in the lower central portion of the operations section near the conical shell. Here is the equipment used for most of the medical experiments, still and motion picture cameras, and the scientific apparatus control panel. This post has cosmonaut restrainers and communications equipment.

Near post No. 4 is the system used to prevent ill effects of weightlessness on the cosmonauts. It includes:

- a treadmill and other devices for physical exercise;
- a bicycle ergometer;
- a pneumatic vacuum suit to create low pressure on the lower portion of the body; and
- a muscle tissue stimulation apparatus.

One of the two portholes at post No. 4 carries an MKF-6M multiple-zone survey camera manufactured by Karl Zeis Jena of East Germany with electronics and control panel.

On the left and right sides near post No. 4 are the refrigeration and drying units of the temperature control system, the onboard radio apparatus, electronic units of the orientation system, and station movement control system.

Post No. 7 works in cooperation with the scientific equipment control post and water regeneration system control. This post is located in the central portion of the small diameter operations section.

Control panels are mounted on the interior to the

left and right; the cosmonaut who works here is restrained in a reinforced seat.

All control panels and cosmonaut working locations are equipped with internal loudspeaker communications devices and daylight lamps. Other lamps are used to create general illumination in the living space. During still and motion picture photography and television reports, the cosmonauts turn on additional lights to provide the necessary illumination for the cameras.

Most of the outer surface of the small diameter operations section is covered with the temperature control system's radiator. On the left and right sides and in the upper portions of the section are three solar battery panels. Special drives rotate the panels toward the Sun at all times. In the forward portion of the operations section are the solar battery orientation system sensors, which determine the position of the Sun in the forward hemisphere as the station moves. Outside the lower portion of the small diameter operations section are the automatic station orientation instruments (an infrared vertical, solar sensor, television orientation device, etc.). Outside the conical portion of the operations section is a special repeating action cover with electric drive to maintain the temperature of the porthole through which the MKF-6M camera operates.

On the outside of the large diameter operations section are the onboard radio system and telemetry system antennas.

To maintain the proper temperature the body of the operations section is covered on the outside with mats of vacuum shield heat insulation, while the large diameter portion of the section is also covered with a fiberglas cover for protection from aerodynamic heating during powered flight. On the sides of the station are panels with sensors to study the flux of micrometeorites.

The unsealed cylindrical equipment section (4.15 m diameter, 2.2 m length) contains:

- the combined motor installation, including correcting motors and a system of low thrust motors which creates controlled torque to orient the station in space; and
- tanks of fuel.

On the outer surface of the equipment section are:

- the approach and docking radio antennas;
- optical lamps for orientation during manual docking of spacecraft with the station;
- the solar battery orientation system sensors, which determine the position of the Sun in the aft hemisphere (with respect to station flight);
- the onboard radio system antennas, and
- a television camera to monitor docking of transport spacecraft.

The equipment section is thermostatted in flight and has external heat insulation similar to the insulation of the operations section. The equipment section is connected to the end of the operations section; its aft end is connected to the booster rocket.

The scientific apparatus section is in the large diameter cylindrical portion of the operations section. It is a combination of conical and cylindrical shells (maximum 2.2 m diameter). The end of the section is oriented toward outer space and is equipped with a cover.

The intermediate chamber of the station is a sealed section consisting of cylindrical and conical shells 2 m in diameter with a total length 1.3 m. The second docking unit of the orbital station is mounted through the conical section on the intermediate chamber.

The intermediate chamber is used to carry equipment delivered by the transport spacecraft. An air line is laid through it to supply air from the operations section to the transport ship to create a common atmosphere. The intermediate section has two portholes used for visual observation, still and motion picture photography and television reporting.

Systems of the Orbital Station, Their Purpose, and Main Operating Modes

1. Onboard Equipment Control System (SUBK).—The SUBK controls the onboard systems:

- automatically (by a programed timer);
- on radioed command from the Earth; and
- on command of the cosmonauts at the control panels.

The SUBK switches the electric power supply system and protects the power supplies from short circuits, controls the pyrotechnic cartridges which open and deploy external elements of the structure, etc., and outputs information on the results of operations to the cosmonauts' panels and to Earth.

2. Orientation and Motion Control System (SOUD).—The SOUD is intended to orient and control the motion of the space station in automatic and manual modes.

The SOUD includes:

- a sensor apparatus (sensing elements):
  - —solar sensor;
  - —infrared vertical device (IKV);
  - —gyroscopic angular motion sensors;
  - —an ionic sensor;
  - —free three-way gyroscope; and
  - —velocity increment integrator.
- manual instruments:
  - —a wide-angle orienting site;
  - —optical orientors;
  - —an electronic-optical converter; and
  - —an astro-orientor.

- the "Kaskad" apparatus to maintain long-term orbital and inertial orientation;
- the approach electronic apparatus;
- lamps and targets for manual approach and docking; and
- automatic equipment and electronic units.

3. Combined Motor Installation (ODU).—The ODU is intended to create controlled torque around the center of mass of the station by means of low-thrust motors, and to generate power to move the station by means of the high-thrust motors.

The combined motor installation includes:

- correcting motors (two); and
- orientation motors.

The motors are supplied with fuel from two groups of collectors, each of which supplies the motors through three station control panels—pitch, yaw and roll.

4. Command Radio Link.—The system is intended to transmit control commands and settings from the Earth to orbit, trajectory measurements, two-way telephone communications between Earth and the station, and television and telemetry information from the station to Earth.

The system includes receivers, transmitters, antenna-feeder device, a programed timer (PVU), decoder, and other electronics and automation equipment.

5. Television Communications System.—The television system is used to transmit color and monochrome images from the onboard television cameras to Earth and to the onboard television screen (VKU).

The system includes:

- external stationary television cameras (monochrome images);
- the reporting television camera (color);
- the reserve reporting camera (monochrome);
- video monitors (VKU);
- the antenna-feeder devices;
- special lamps; and
- automation and electronic equipment.

6. Telephone Communications System.—The "Zarya" radiotelephone communications system is intended to provide two-way Earth-station and station-spacecraft communications in the ultra-short wave (USW) and short wave (SW) bands. The system includes USW receivers and transmitters, SW receivers and transmitters, and antenna-feeder devices.

To provide loudspeaker communications within the sealed station sections, there are loudspeakers, microphones, and amplifiers at the control posts and working locations.

The transmission of text (alphanumeric) information from Earth to the station utilizes an apparatus with a printer.

7. Radiotelemetry Communications system (RTS).—The radiotelemetry system is designed to collect information and transmit it from the spacecraft to Earth. The station carries two RTS systems; one system is used for service information, the other for information from the scientific and experimental apparatus.

Independent magnetic recorders (MIR) with magnetic tape cassettes are used to record scientific measurements with high sampling frequency. The magnetic tapes are returned to Earth on transport spacecraft.

8. Orbital Control Radio System, Which Performs Trajectory Measurements.

9. Power Supply System.—The power supply system (SEP) provides electric power for all onboard systems of the station, and also charges the buffer batteries (BB) and supplies power to transport spacecraft docked to the orbital unit.

The system includes:

- solar batteries (SB); three solar battery panels are installed on three planes of the station;
- the main buffer battery (BB);
- the reserve buffer battery; and
- the power supply test unit (BKIP).

The SB panels are oriented toward the Sun by means of the solar battery orientation system (SOSB). When a minimal voltage is reached, all consumers are automatically disconnected except for the duty systems, and a switch is made to the reserve BBO. After spacecraft dock, the orbital unit SEP charges the BB and supplies the transport spacecraft as long as they remain docked.

10. Life-support system (SOZh).—The SOZh is intended to provide conditions which will support the life of the crew; proper pressure and gas composition of the atmosphere, food and water, sanitary-hygienic conditions, and space-walk support.

The gas composition support system (SOGS) is intended to liberate oxygen (O_2) and absorb carbon dioxide (CO_2) and other impurities.

The system includes:

- chemical O_2 regenerators;
- chemical CO_2 absorbers;
- gas analyzers;
- harmful impurity filters (FVPs);
- dust filters (PFs); and
- gas stored in cylinders.

Additional regenerators, absorbers, FVPs, and gas are delivered by transport and cargo ships to replenish the supplies and allow continued operations of the system.

The system can maintain the parameters of the atmosphere within assigned limits (CO_2 = 0.9 mm mer-

cury (Hg) O_2 = 160-280 mmHg, total gas pressure 760-960 mmHg) by manual connection and disconnection of regenerators and absorbers according to the readings of the gas analyzers.

The crew is supplied with water by regeneration of water from atmospheric moisture condensate and by reserves of stored water.

The water is stored in special containers.

Food is stored onboard the station as daily pacs in boxes. The food supply is supplemented by delivering it on transport and cargo spacecraft.

Sanitary-hygienic conditions are maintained onboard the spacecraft by means of a sanitary installation (ASU) [head—Tr.], shower, sets of linen, personal hygiene washcloths, and two lock chambers (ShK) with containers for waste ejection. Liquid wastes are collected in the sanitary device and ejected through the locks. Solid wastes (ASU, food, etc.) are collected in packets, then placed in special rigid containers designed for ejection through the locks.

Two spacesuits are used to allow two cosmonauts to perform space walks simultaneously. The transit section is used as a lock for this purpose.

11. Medical Monitoring and Prophylaxis Equipment.—This equipment is designed to allow regular medical monitoring of the cosmonauts' health and prevent harmful effects of spaceflight factors.

The system includes medical testing apparatus, an "Aelita" combined medical examination apparatus, a treadmill, bicycle ergometer, pneumatic vacuum suit, units for testing and indicating parameters of the crew's condition upon orbital insertion, and a pharmacy.

These devices are used for:

- regular medical testing, the information from which is transmitted to Earth through the telemetry channels;
- periodic medical examination with the "Aelita" apparatus, the data from which are recorded onboard the spacecraft and transmitted to Earth; and
- regular crew training (with a treadmill, bicycle ergometer, and pneumatic vacuum suit).

12. Temperature Regulation System (STR).—The STR is intended to support the proper temperature of structures, units, and apparatus of the orbital station and docked transport spacecraft, and to create comfortable temperature conditions within the habitation sections.

13. Docking and Internal Transfer System (SSVP).—The SSVP is intended to perform mechanical, electrical, and hydraulic docking of the orbital station with transport and cargo spacecraft, and to support internal transfer of cosmonauts from spacecraft into the station without passage through open space.

The docking unit is based on the rod (active portion) and cone (passive portion) principle.

The Soyuz T Transport Spacecraft

The Soyuz T spacecraft is an improved manned transport spacecraft for the delivery of the crew to Salyut orbital stations and return of the crew to Earth, as well as transportation of cargo.

The experience gained in the development of flights of Soviet spacecraft and stations was used extensively in designing the Soyuz T spacecraft.

The Soyuz T spacecraft is placed in orbit by a Soyuz booster rocket, which determined the size and mass of the new spacecraft. The well-proved Soyuz spacecraft, including the descent module, orbital (habitation) section, and instrument-equipment section, was used as the basis for arrangement of the new spacecraft.

However, the Soyuz T spacecraft differs in a number of details from the earlier craft, has improved characteristics and, particularly, increased effectiveness as a transportation vehicle for orbital space stations, plus improved reliability and crew safety.

The spacecraft is designed to carry up to three crew members in space suits. In addition to the special onboard systems, the spacesuits protect the crew in case of a loss of seal in the living spaces. If necessary, depending on the mission of each specific flight, the spacecraft crew may be reduced in number with no changes in spacecraft design. The free spaces are then used to carry special cargo containers, allowing, in combination with Progress spacecraft, the problem of delivering cargo to the station and returning cargo from the station to be solved.

Most of the onboard systems of the spacecraft were designed anew or modernized using systems design principles, new elements, and new production and testing technologies.

A new motion control system has been developed for the spacecraft, using an onboard digital computer. The system calculates motion parameters and automatically controls the spacecraft in the optimal mode with minimum fuel consumption, performs self-testing, and automatically switches if necessary to reserve programs and hardware, while outputting information to the crew via the onboard display.

The decisions implemented in the system assure higher accuracy, reliability, and flexibility of spacecraft control in both orbital flight and descent.

The crew can control the spacecraft manually not only in orbit but also during descent in the atmosphere.

The approach and correcting motor and docking and orientation micromotors operate with the same fuel components and have a common fuel storage and supply system, allowing more effective utilization of onboard fuel reserves. During flight the consumption of fuel is monitored by a special measurement system.

In order to improve reliability, the landing equipment system has been modernized, and the emergency crew rescue system, used as the spacecraft is placed in orbit, has been improved.

The radio systems of the spacecraft—such as the command-program radio link and radiometry and television systems—have been improved, and solar batteries have been included in the power supply system.

The design of the spacecraft provides for duplication of important mechanisms, sealing devices, separator units, etc.

The total volume of the living spaces aboard the Soyuz T is about 10 m³.

The Progress Automatic Transport Spacecraft

The automatic transport spacecraft is intended for delivery of the following items to the Salyut piloted orbital station:

- scientific apparatus, photographic materials, crew life-support supplies, instruments, and units in need of replacement; and
- fuel components to recharge the combined motor installation of the orbital station.

In addition, it provides for the removal of wastes and units which have completed their operating life from the space station.

The automatic cargo transport spacecraft has a launch mass of 7 tonnes and consists of three main structural units:

- the cargo section (GO) with docking unit;
- the fuel component section (OKD); and
- the instrument and equipment section (PAO), consisting of the transit, instrument, and equipment sections.

The docking unit of the spacecraft is based on the docking unit of the Soyuz manned spacecraft and is designed for mechanical docking of the spacecraft with the station, to assure an airtight seal, and also to connect electrical lines and automatically connect and seal the main fuel supply lines. The crew passes through the docking unit into the cargo section of the spacecraft.

The cargo section of the spacecraft is intended to carry instruments, scientific apparatus, photographic materials, food, water, and life-support system equipment, including regeneration installations, all mounted on special frames and in containers. Throughout the flight, with the docking unit hatch sealed, conditions are maintained in the cargo section as required to preserve all of the instruments and food products being delivered to the space station. The volume of the cargo section is 6.6 m³. The cargo section has an ordinary air atmosphere (760 mmHg). The temperature in the section is maintained between +3° and +30° C.

The cargo section is connected to the refueling component section. On the outer surface of the section are three antennas of the electronic approach system, two external television cameras (one aimed forward, the other toward the Earth), 103 light indices (used by the crew to monitor correct placement of the spacecraft during automatic approach and docking). Outside the section are the main lines which feed fuel components from the refueling section to the connections on the docking unit. The cargo section of the spacecraft can carry up to 1,300 kg of cargo to the orbital station.

The refueling component section structurally consists of two truncated conical shells. The section connects at one end to the cargo section, at the other end to the transit section and instrument and equipment section. At the outside of the section are two light indices which supplement the light index on the cargo section. This section is intended to carry tanks of fuel components for delivery to the orbital station, gas cylinders, and the equipment of the refueling system. The gas in the cylinders (nitrogen or air) is used to drive the fuel components during the refueling and also to fill the habitation compartments of the station if necessary.

The refueling system includes a system which tests the seal of the fuel lines, a blowing system, and sensors to monitor the temperature and pressure of the components and gas in the process of storage and refueling. During refueling, up to 1 tonne of fuel components can be transferred to the tanks of the combined motor installation of the station.

The refueling system is controlled by the crew of the orbital station, with radio signals from Earth controlling the cargo spacecraft end.

The instrument and equipment section is designed to carry all of the main service systems of the spacecraft supporting independent flight, approach and docking, flight as a part of the orbital station, and undocking.

The transit section of the instrument-equipment section is a framework which carries the fuel tanks, spherical containers, and fittings of the approach and orientation system motors. Outside the section are 10 approach and orientation motors of the system and the command radio link antenna.

The instrument and equipment sections are similar to the instrument and equipment sections of the Soyuz transport spacecraft in their design, purpose and apparatus, and equipment carried.

A Soyuz booster rocket is used to insert the transport cargo spacecraft into orbit.

After the cargo spacecraft separates from the booster rocket, structural elements carrying the antennas of

the electronic approach system and radiotelemetry system, as well as the panel carrying the light indices, are deployed from the spacecraft.

Basic Information on the Soyuz Booster Rocket

The Soyuz booster rocket has three stages.

Stage I consists of four lateral units, each of which is 19 m long, 3 m in diameter; its motor has four chambers, two of which are steering chambers, developing a total thrust in a vacuum of 102 tonnes.

Stage II is the central unit, about 28 m in length, maximum 2.95 m in diameter, its motor has four chambers, all of which are steering chambers, developing a total thrust in a vacuum of 96 tonnes.

Stage III is a unit with a length of 8 m and a diameter of 2.6 m; its motor has four chambers (with steering nozzles), developing 30 tonnes of thrust in vacuum. The launch mass of the booster rocket with a Soyuz T spacecraft aboard is over 300 tonnes.

When the booster rocket is launched, the motors of the first and second stages are ignited simultaneously. The second stage continues to operate after the four lateral units [of the first stage] are jettisoned. The third stage is ignited after the second stage motor has completed operation. The booster rocket uses kerosene-oxygen fuel in all stages. The total length of the booster rocket with a Soyuz T spacecraft is 49 m. The maximum diameter at the stabilizers is 10.3 m.

Controlling the Flight of the Salyut Orbital Scientific Station

Organization of Flight Control

Flight control of the Salyut orbital scientific station, transport and cargo spacecraft is provided by:

- the flight control center near Moscow;
- a network of tracking stations;
- a system of modeling devices including a mathematical model of the station and a physical model of the spacecraft; and
- a communications system with Earth and satellite-information transmission channels.

Flight Control Center

The flight control center performs the following tasks:

- operational administration and coordination of the operation of the entire system;
- collection, processing, and display of telemetry, trajectory, and television information arriving from the station and from transport and cargo spacecraft; and
- interaction with the launch and search and rescue systems, trainers and modeling equipment, and various organizations participating in flight support.

The flight leader and flight control personnel are located at the center. The flight control center is equipped with a computer system; devices for collection, processing, and display of information; internal communications and television; remote-command output; communications with the crew; and transmission of telegraph messages to the Salyut station. The control center is in communications with the Moscow television technical center at Ostankino.

The flight control center has been significantly improved. It now has a second control room to control the flight of the transport and cargo spacecraft and a modernized computer system which now allows the problem of controlling several spacecraft simultaneously to be solved. At the same time the number of communications channels between the center and tracking stations has been increased to support simultaneous transmission of telephone, telemetry, and television information to the center from three spacecraft over surface channels and through Molniya communications satellites.

The modernized computer system of the center and the improved communications system allow transmission, processing, and display of information from all telemetry sensors of the Salyut station and from Soyuz spacecraft simultaneously for the control personnel.

The flight control personnel operating with the Salyut and Soyuz spacecraft systems are a carefully selected trained team consisting of specialists of various profiles. They include specialists on the flight program and flight control organization specialists, onboard systems developers, designers of the station and transport spacecraft, scientists, ballisticians, physicians, communications specialists, as well as specialists on the control and maintenance of the tracking stations, flight control central hardware, communications system hardware, plus representatives of scientific organizations of our country and other socialist countries.

Most of the control personnel are located at the flight control center—this is the chief operational flight control group. Some of the personnel are located at tracking stations and on ships of the U.S.S.R. Academy of Sciences, the Priroda state scientific research and production center, and the center for medical and biological research. The total number of personnel is about 100. Successful performance of the flight mission and completion of scientific research and crew safety depend on precise operations by every man.

The organizational structure of the flight control center personnel was developed by specialists with experience in the organization of manned spacecraft and station flight control, is recorded in special organizational documentation, and has been repeatedly tested in training exercises and in controlling the flights of previous stations and manned spacecraft.

The flight leader heads the control personnel.

Flight control is performed from two rooms: the main station flight control room and the transport and cargo spacecraft control room.

The personnel in the rooms work under the control of shift flight leaders.

Each room contains: the shift flight leader; specialists responsible for the main onboard systems; persons responsible for the operation of tracking stations; persons responsible for planning the flight program and for complete analysis of the operation of onboard systems; a cosmonaut operator in communication with the crew; representatives of the organizations which develop the station and spacecraft; a ballistics expert; a physician responsible for medical monitoring of the crew; the shift center leader; and specialists responsible for the main system at the center (communications, computer system, display systems, etc.).

All specialists work at positions with individual display and communications equipment.

The personnel work in four shifts. Shift changes occur during flight with no delay in flight operations.

Since the flight control center, tracking stations, and communications equipment are all the same for the station and the transport spacecraft, priority had to be assigned for their use. During orbital insertion, approach, and docking of the transport spacecraft with the station, the transport spacecraft control room has priority for use of equipment.

After docking and movement of the crew into the station, priority is transferred to the main control room. Priority transfer occurs at the moment the transfer hatches between the spacecraft and station are opened.

Organization of Work in Control Room

Control of the station or transport spacecraft is transferred to the control center from the launch complex immediately after separation of the last booster rocket stage.

Up to this point the personnel in the control rooms monitor the operation of onboard systems by telemetry, observe the crew by television, and listen to the conversations between the crew and the launch team.

A central screen shows the course of the booster rocket's flight over the entire insertion trajectory. After separation of the spacecraft from the booster the personnel in the control room monitor the opening of the antennas by telemetry, make contact with the crew, and begin testing onboard systems.

Work in the room is organized as follows: When the spacecraft enters the zone of visibility of ground tracking stations (the movement of the spacecraft is displayed on the central screen in the main hall) commands are transmitted to the spacecraft in accordance with the flight program. The personnel in the room monitor the transmission of commands and their reception by the spacecraft. The necessary onboard systems are switched on by commands from Earth or by the crew. The tracking stations begin to receive and transmit to the control center the telemetry, trajectory information, and television images received from the spacecraft. As the telemetry and trajectory data are received they are automatically processed by the control center's computers and transmitted to the display devices in the control room.

Telemetry information is analyzed in detail by systems specialists who generate conclusions concerning the status and operation of each onboard system for the responsible personnel.

Those responsible for individual systems are in communications with the support personnel outside the control center and can, if necessary, consult with them or obtain additional information on the operation of the systems.

In case of abnormal operation of spacecraft systems, the specialist responsible for overall analysis determines the effect of any system failures on the operation of individual systems, prepares suggestions for elimination of defects and correction of onboard system-operating modes, and then reports these suggestions to the shift flight leader.

The physician responsible for medical monitoring performs detailed analysis of biotelemetry data, estimating the condition of the crew and reporting it to the shift flight leader.

As trajectory information is processed and orbital parameters are determined, the ballistic data are automatically transmitted to the control room displays.

The communications operator carries on planned radio conversations with the crew. The person responsible for the tracking stations monitors their operation and, if there is any deviation from the planned program, informs the shift flight leader and takes steps to eliminate deviations.

The onboard computer specialist monitors operation of the computer and, if necessary, prepares changes to the computer program which are then transmitted to the spacecraft.

The center shift leader monitors the operation of all services at the center and, if there are deviations in any operations, informs the shift flight leader and takes steps to eliminate them.

The shift flight leader, considering all the information which he receives, makes decisions concerning the future flight program. If there are no deviations in the operation of onboard and ground-based systems, permission is given to perform operations in accordance with the planned program.

If it is necessary to correct the program, the correction is made by the person responsible for planning the program. Correcting actions may be undertaken during a session or in subsequent sessions. If necessary in order to identify failures and test correcting actions, a mathematical model of the station or the combined spacecraft physical model may be used. Decisions are implemented by transmitting instructions by radio from the flight control center to onboard systems or by verbal transmission of instructions to the crew.

Control Room Operation Support

In addition to the major specialists in the control room, there are also support groups at the center. The specialists in these groups are located in separate rooms equipped with positions similar to those in the control rooms. The main tasks of these personnel are to provide:

- support to personnel in the control room with calculations and information which can be used to make decisions concerning the flight program;
- consultation with control room specialists and assistance to them in analyzing the operation of onboard systems;
- assurance of implementation of decisions made by the shift flight leader;
- support for the operation of the technical equipment at the center; and
- prospective flight planning.

The personnel include the following specialists:

- specialists in onboard systems preparing and transmitting to the display devices the necessary additional information to control room specialists;
- specialists in operational planning of the flight program, to prepare, if necessary, changes to the flight program;
- specialists in advanced planning of the flight program (1 week);
- specialists in coordination of tracking station operations;
- specialists in communications which support communications of the center with the spacecraft and tracking stations;
- specialists in ballistics, included in the main ballistic center staff and performing the necessary ballistic calculations to determine the orbit, zones of visibility, entry and exit of the spacecraft from the shadow, maneuvers, as well as data necessary for scientific experiments;
- onboard computer specialists;
- representatives of the search and rescue system, constantly ready to go to work in case of an emergency return of the spacecraft;
- the medical monitoring group, which regularly analyzes biotelemetry and maintains communications with the flight medical support center;
- a group which plans the program for the crew's day off, prepares music transmissions for the crew, radio conversations between the crew and their families, and cultural and scientific activities; and
- to provide consultations to the flight leaders during experiments sponsored by representatives of another Socialist nation, the flight control center includes a consultation group of specialists representing the sponsoring nation.

Training of Control Personnel

Before starting to work at the center, control personnel undergo a training cycle. Training is performed using the mathematical model of the Salyut space station, the physical model of transport spacecraft, and training machines. Actual tracking stations and communications devices are used in these training exercises. The crew of the Soyuz T spacecraft participate in the training as well.

Training exercises are performed under conditions as close to those of real flight as possible. The flight program is developed in real time with interactions among individual groups of control personnel, the flight control center, and the tracking stations. Nonstandard situations which may develop on board and on ground are simulated. The most difficult flight stages are run through repeatedly.

The Baykonur Kosmodrom

The Baykonur Kosmodrom is a complex organization with many branches, a combination of unique devices, automatic systems, and engineering structures serviced by specialists of many sorts.

The Baykonur Kosmodrom is located in the Kazakh SSR in a semidesert area with a continental climate

(hot, dry summer and cold, dry, windy winter). It was founded in 1955.

The reasons for selecting the location of the Kosmodrom were that it is remote from large populated areas, thus allowing safe rocket launches to be assured and separation zones (i.e., areas for the landing of returning spacecraft) to be set aside, and that many days in this area are cloudless.

Launches are performed from the Baykonur Kosmodrom in accordance with the national space research and utilization program of the U.S.S.R., in cooperation with other socialist nations in the "Interkosmos" program, and also in accordance with agreements for joint operations concluded with the United States, France, and other nations.

The world's first artificial Earth satellite was launched from the Baykonur Kosmodrom, the first cosmonaut Yu. A. Gagarin, and the first woman V. V. Tereshkova started from Baykonur; the Luna, Venera, Mars, and Zond automatic interplanetary stations were launched here, as were space stations and artificial Earth satellites of various types (Kosmos, Elektron, Polet), and the Molniya series of satellites used to relay television programs and to provide long-distance telephone and telegraph communications.

Manned Soyuz T spacecraft and Salyut orbital stations are regularly launched from the Baykonur Kosmodrom.

The Kosmodrom is used for assembly, testing, and launching of booster rockets with spacecraft, as well as for final prelaunch preparation of the cosmonauts.

The main component parts of the Kosmodrom are:

- the booster rocket assembly and testing building;
- the spacecraft assembly and testing building;
- the launch areas; and
- observation, command, and telemetry points.

The residential area of the Kosmodrom is located some tens of kilometers from the launch area and technical buildings. Here we find the cosmonaut training complex (classrooms for technical and scientific training of crews, the sports complex with swimming pool, laboratories to prepare the cosmonauts for flight, and the medical complex), as well as the institute, technical school, schools, club, stadium, television center, etc.

The Kosmodrom is connected to other points in the nation by air, highway, and rail. The territory of the Kosmodrom also has a well-developed network of highways and railroads.

The operations of assembly, testing, and joining of booster rockets and spacecraft are performed at the technical positions in the installation and testing buildings of the Kosmodrom, which are equipped with the necessary testing and measurement equipment and tools.

A number of launch and technical positions have been constructed at the Kosmodrom. One of the most important is the position from which three-stage booster rockets carrying the Vostok, Voskhod, Soyuz, and now Soyuz T spacecraft are launched.

The launch structure for this booster rocket includes a launch system with releasable supporting beams. The rocket is "suspended" in the launch system by the supporting units. The rocket system is delivered to the launch position from the assembly and testing building of this technical position, where it is assembled in the horizontal position.

The launch complex of the system, equipment, and engineering structures used to transport the rocket system to the launch position, set it in the launch structure, and perform prelaunch testing includes:

- the transporter and erector;
- the launch structures;
- the launch system (supporting frames and restraining devices; cables, hoses, and cable towers);
- the servicing devices (servicing frames and cabin); and
- the fuel and oxidizer supply systems.

The launch and other structures also contain: systems for filling and thermostatting fuel; a compressor station; compressed-gas receiver; fuel storage tank; a system to control both the preparation of the rocket for launch and the actual launch; the command point bunker, connected by communications lines to all operational services of the Kosmodrom; observation and command-measurement points; and the flight control center.

Preparation of the booster rocket for launch begins with transportation of its stages and sections of the spacecraft in special railroad cars from the manufacturing plants. The individual stages of the booster rocket are delivered to the spacecraft assembly building, where they are automatically tested, assembled, and prepared to be joined with the spacecraft. The spacecraft is assembled and tested in the spacecraft assembly building.

The ship is filled with fuel components and compressed gases at the filling station of the Kosmodrom, to which the spacecraft is delivered in a special railroad car. After it is filled and final operations are performed, the transit section and nose fairing are attached to the spacecraft. The assembled forward unit is then attached to the booster rocket, and the entire rocket-spacecraft system is tested.

This completes the work at the technical position, and the space system is delivered to the launch position on its transporter.

To install the rocket on the supporting beams of the launch system, the transporter raises the rocket to the

vertical position by means of hydraulic jacks. During this time the supporting beams are shifted from an inclined position to their operating position and accept the weight of the rocket in its central (supporting) belt. The rocket is thus suspended over the gas-deflecting trough. Its tail portion is several meters below ground level. This helps to protect equipment on the ground from the powerful high-temperature jet of the motors.

The transporter, after placing the rocket on the supporting beams, lowers its boom to the horizontal position and rolls away the launch system. The servicing booms, cable, and hose towers are brought up to the rocket. As soon as they are in their operating position the process of azimuthal guidance of the rocket and placement of the rocket in the strictly vertical position is begun. All of these operations are performed by mechanisms on command of the remote control system. The air system which controls the temperature of the spacecraft is then started up. The essence of this operation is feeding of air beneath the fairing of the booster rocket at a rate such that the apparatus and fuel components remain within a defined temperature range. The air thermostatting system continues operating almost up to the moment of launch.

After the various lines are connected (fuel, drainage, pneumatic, electrical) to the rocket and spacecraft, the next operation begins—pressure-testing, i.e., checking the tightness of seal of all connection points with compressed air. Any pressure drop indicates a leak.

The testing and launch apparatus then begins prelaunch testing of the onboard systems and units of the rocket. All onboard systems are tested to determine if they are functioning properly and their initial conditions are correctly set; individual onboard and ground-based instruments are checked (without starting the standard programs or turning on the actuating organs); the television, communications, command radio link, onboard power supply, and other systems are tested. The results of prelaunch testing are displayed on all video-monitoring devices and recorded by the telemetry systems and multichannel recording machines. If all onboard system and unit parameters are normal, permission is given to begin fueling the booster and filling its compressed-air tanks.

The transfer of liquid oxygen into the booster is a special operation. The lines and tanks are first cooled; i.e., their temperature is artificially reduced to prevent the liquid oxygen from boiling off and to reduce the pressure in the booster's tanks and lines. For this purpose a small quantity of liquid oxygen is fed in from the storage container. As it evaporates, it cools the tanks and lines then passes through the safety and drainage valves in the gaseous state. After the tanks and lines are cooled, the pumps begin to operate. The level-monitoring system (SKU) assures precise measurement of fuel components.

Control of the filling process and monitoring of the transmission of instructions are performed remotely from the launch-pad command point.

At the same time as the booster rocket and the spacecraft are fueled, their systems, instruments, and units undergo final testing, adjustment, and simulated operation, and commands are transmitted to the memory unit of the onboard control system—it is set up to perform a definite program of orbital insertion.

Since liquid oxygen evaporates it must be topped off; i.e., additional liquid oxygen is pumped in to fill the tanks to the required level. The fuel components are then drained from the filling lines, after which the filling, drainage, and pneumatic lines are disconnected, and the correct vertical position and azimuthal guidance of the rocket are tested.

Two hours and thirty minutes before the launch the cosmonauts take their places in the spacecraft. The final prelaunch and launch operation program is started. The automatic system assures a launch at the precise time with an accuracy of a few hundredths-of-a-second. Final monitoring of all rocket system before the launch is performed by telemetry.

At minus 1 minute, when it becomes clear that all systems and units of the booster rocket and spacecraft are operating properly and the cosmonauts are ready for the launch, the operator places a switch in the "launch" position. The automatic final launch-operation program is started. Operations performed are displayed on the control panel. The fuel-and oxidizer-tank drainage lines are closed at this time. The cable and hose towers swing away from the rocket. The turbine pumps begin operating. The ignition is turned on. The pyrotechnic ignition devices create flames in the chambers of the first- and second-stage motors. The motors develop thrust, operating in the preliminary, intermediate, and then main operating modes. When the motor thrust exceeds the weight of the booster rocket it begins to rise and is freed from the clamps of the launch system support beams. At this instant a contact closes and the "launch" light begins to shine on the control panel. Information on the prelaunch preparation and insertion of the spacecraft into orbit is sent to the flight control center, where it is processed and displayed on the common and individual screens in the control rooms. Control of the

spacecraft is transferred from the launch complex to the flight control center immediately after separation of the third stage of the booster rocket.

Command, Measurement, and Search and Rescue Systems

The flight of the Soyuz T spacecraft is controlled through the U.S.S.R. command and measurement complex, based on seven tracking stations in the Soviet Union—Dzhusaly, Yevpatoriya, Ussurisk, Ulan-Ude, Kolpashevo, Tbilisi, Petropavlovsk-Kamchatskiy, U.S.S.R. Academy of Sciences research vessels in the Atlantic and Pacific Oceans, and the USSR Academy of Sciences computer centers. These ground-based and ocean tracking stations are located so as to provide communications with the station and transport spacecraft in all orbits of the flight.

The longest continuous communications with the crew are provided for those orbits when the spacecraft dock, the crew move out for a space walk, or the spacecraft begins its return from orbit.

Command program information is transmitted from the control center to the tracking stations through automated telephone communications lines and is relayed from there to the orbital station. Telemetry and television information can also be recorded at the tracking stations for subsequent transmission to the flight control center.

The ground-based complex is a component part of the Salyut space station and Soyuz T spacecraft flight control loop. The control loop includes: the flight control center, ground-based and shipboard tracking stations, the ground and satellite communications system, and ballistic centers.

As it controls the flight, the ground-based control complex performs the following tasks:

- exchange of all types of information between the spacecraft and the flight control center;
- provision of two-way telephone and telegraph communications between the control center and the spacecraft crew;
- measurement of the parameters of the spacecraft's motion;
- organization of communications between elements of the ground-based control system and the flight control center; and
- operational administration and coordination of operation of tracking stations and other elements of the ground-based system.

The tracking stations in the process of a flight measure the parameters of the spacecraft's motion and receive telemetry and television information from the spacecraft. All decisions related to flight control are implemented through the tracking stations by conducting conversations with the crew and transmitting radio commands to the spacecraft.

There are about 20 telephone and telegraph communications channels between the center and a typical tracking station. Most tracking stations have wideband communications channels with the center. The tracking station is equipped with a computer which can perform about 50,000 operations per second. Elimination of telemetry redundancy from the flow of telemetry information is performed by specialized apparatus. The throughput capacity of the data transmission apparatus used over the telephone channels is 2,400 bps.

Shipboard command and measurement points receive and transmit to the center the complete flow of telemetry information from the spacecraft. Molniya communications satellites are used in the satellite communications system.

The tasks of the search and rescue complex include:

- search for and location of the returning spacecraft and cosmonauts,
- determination of the coordinates of their landing,
- evacuation of the cosmonauts and provision of medical aid,
- technical servicing of the spacecraft, and
- its removal from the landing area to its assigned point.

The men and equipment of the search and rescue complex are placed where the returning spacecraft will land. Helicopters and aircraft, observing the spacecraft visually and by radio, converge on their assigned locations along the landing track, using radio direction finding to approach the spacecraft and accompany it as it comes in for a landing, and maintain two-way communications with the crew.

The returning spacecraft land in a selected area of the Soviet Union. The descent apparatus is designed to land on dry land; the apparatus has special systems assuring safety of the cosmonauts should it land in water.

In the landing area the cosmonauts are met by a specially trained search group. This group includes technical specialists and physicians. The search group is provided with everything necessary to reach the landing point rapidly and to provide any needed assistance to the cosmonauts.

The search aircraft carry parachute personnel including physicians and rescue specialists who if necessary parachute to the spacecraft after it lands. Search and rescue equipment includes aircraft and helicopters, ships and all-terrain vehicles. The technical specialists and physicians included in the search group are well-trained parachute jumpers and scuba divers. The physicians of the group have available the necessary medical equipment and medications, adapted for use under any weather conditions.

After landing, the cosmonauts open the hatches of the spacecraft and prepare containers of scientific apparatus and photographic film for transportation. If necessary they can use the reserve stores onboard the spacecraft, including warm clothing, swimsuits, signaling and radio communications devices, extra water, and other necessary products. After landing and leaving the spacecraft, the cosmonauts take off their spacesuits and put on flight clothing. The containers of scientific apparatus and film are turned over to the specialists in the search group. The cosmonauts undergo post-flight physical examination at the landing point.

If the spacecraft lands in water, the cosmonauts remove their spacesuits, don special equipment, prepare to use their flotation devices, and maintain contact by radio with the search service. The search group which arrives at the landing zone helps the cosmonauts to leave the spacecraft.

The search process, location of the spacecraft, and evacuation of the cosmonauts from the spacecraft and from the landing zone are all reported from the area in which the search and rescue complex operates to the flight control center.

The Yuriy Gagarin Cosmonaut Training Center

The Yuriy Gagarin Cosmonaut Training Center (TSPK) was created in 1960 and is located outside Moscow, in Zvezdnyy Gorodok [Star Village].

The cosmonaut training center is an institution provided with modern equipment and manned by qualified specialists, capable of training crews for space and expeditions in accordance with the increasing demands of the time.

The specialists at the Center have accumulated great experience in educational, scientific, and indoctrination work. They take part in studies of the prospects of using manned spacecraft, and contribute to the improvement of spacecraft and their equipment and to the planning of future flights.

The structure of the TSPK, the mission of its main subunits, and [the composition of its] professional staff of specialists are determined by the tasks which it performs in preparing and supporting space flight.

In 1968 the Center was named in honor of Yuriy Gagarin.

In 1971, for its great services in the preparation of crews for spaceflight, its participation in the mastery of space, and in connection with the 10th anniversary of the world's first manned space flight, the center was awarded the Order of Lenin.

During the operation of the TSPK (up to June 1, 1982) 49 manned spacecraft crews were trained, including: 6 for the Vostok spacecraft, 2 for the Voskhod spacecraft, 37 for the Soyuz spacecraft, 4 for the Soyuz T spacecraft. Sixty cosmonauts had been in space, including 10 three times (Vladimir Shatalov, Aleksey Yeliseyev, Valeriy Bykovskiy, Petr Klimuk, Nikolay Rukavikhnikov, Valeriy Kubasov, Valeriy Ryumin, Viktor Gorbatko, Oleg Makarov, Vladimir Kovalenok), and 15 twice, as well as 9 cosmonauts who were citizens of other Socialist nations: Vladimir Remek (CSSR), Miroslav Germashevskiy (Poland), Zigmund Jen (GDR), Georgiy Ivanov (Bulgaria), Vertalan Farkash (Hungary), Fam Tuan (Viet Nam), A. Tamayo Mendes (Cuba), Zhugderdemidiyn Gurragcha (Mongolia), and Dumitru Prunariu (Roumania).

In 1980 the cosmonaut training center celebrated its 20th anniversary.

Appendix B

Soviet Space Stations: Achievements, Trends, and Outlook

Geoffrey E. Perry, MBE
November 1982

My mathematical conclusions, based on scientific data verified many times over, show that with such devices it is possible to ascend into the expanse of the heavens, and perhaps to found a settlement beyond the limits of the Earth's atmosphere. . . . People will take advantage of this to resettle not only all over the face of the Earth but all over the face of the Universe. . . .

—K. E. Tsiolkovsky 1903

It is a widely held belief that the Soviet space program deliberately follows the paths described in the early years of the century by Konstantin Tsiolkovsky.[1] Be that as it may, it is certainly possible to find close parallels between Tsiolkovsky's writing and the course of events, but more likely these parallels result because modern engineers have arrived at similar solutions to the same problems rather than because of slavish obedience or preconceived notions.

Smolders[2] holds that the concept of space stations forms the nucleus of Tsiolkovsky's vision of space travel. Tsiolkovsky considered the construction of a permanent base in space to be the first important step towards a landing on the Moon and exploration of the planets. A space station concept attributed to Tsiolkovsky depicting a closed ecological system and garden, laboratories, living quarters, and a docking port with an airlock has been reproduced in official Soviet publications. Illustrations of other space stations appearing on commemorative stamps owe more to the designs of Shternfel'd and others which are to be found in a handbook produced by the staff of the Battelle Memorial Institute.[3] A 1964 Soviet Defense Ministry book on *Manned Space Stations* listed the building of a larger manned space station, with a crew of 30 to 50, in the 1972-75 period, as the third of five further stages in space conquest.[4] To date, the maximum number to man a complex at any one time has been five for the Apollo-Soyuz mission and two visits to Salyut 7.[5]

After the "troika" mission of Soyuz 6, 7, and 8 in 1969, Leonid Brezhnev said, "Soviet science views orbital stations with interchangeable crews as man's major highway into space. . . . Major scientific laboratories will appear for conducting research in space technology and biology, medicine and geophysics, astronomy and astrophysics."[6]

According to Feoktistov and Markov, direct work on Salyut space stations began in 1969.[7] To reduce cost and to shorten the construction time as many units and separate systems as possible were used from Soyuz, Zond, and other tried and tested designs. Most of these needed modification as they did not provide the required service-life, and basic systems, such as the heat supply, were built from scratch. The intention of using the manned mode opened up the possibility of in-orbit repair and replacement of defective subsystems, thereby increasing the reliability and life of the station.

A study of Soviet space station philosophy demands consideration of Salyut, Soyuz, and Progress spacecraft as components of an orbital complex. The Soyuz acts as a manned transport craft between Earth and the orbiting space station, remaining docked with the station whilst the crew is on board, in the same manner as the Apollo was used for three missions to Skylab and, presumably, the Shuttle orbiters will be used with any future National Aeronautics and Space Administration (NASA) space station. Progress, a Soyuz derivative, has an unmanned role as an expendable cargo vehicle.

Although certain events in the history of the Soviet space program have been spectacular at the time, it must be realized that they are not instant technological breakthroughs but rather are the results of careful planning and cautious steps towards the desired goals. The docking of the Soyuz 4 and 5 spacecraft in 1969, claimed as establishing "the world's first orbital space station,"[8] should be seen as the first docking of two manned Soviet spacecraft following two successful automatic dockings of unmanned satellites in the Cosmos series.[9] The clue to the intended function of the Soyuz was to be found in the name "Union," although a characteristic element of ambiguity was also present. The EVA transfer of cosmonauts between the two spacecraft demonstrates the step-by-step approach and unsophisticated design philosophy.[10] Internal crew transfer was not accomplished until Soyuz 11 docked with Salyut 1 more than 2 years later.

The Soyuz T (T = transport) currently in use with the Salyut 7 space station has evolved through several variants. Tested unmanned in the Cosmos series, Soyuz 1 malfunctioned and killed cosmonaut Komarov during the return to Earth when the parachute failed to deploy correctly.[11] This resulted in an 18-month period of redesign before testing recommenced with the unmanned rendezvous and docking of Cosmos 186 and 188. As in Voskhod, crews flew without spacesuits and a three-man capacity was demonstrated with Soyuz 5 although, for the Soyuz 9 recordbreaking 18-day flight, the crew was reduced to two to permit sufficient consumables to be carried. The loss of the crew of Soyuz 11 returning from the 24-day mission to Salyut 1 necessitated a further period of redesign.[12] To accommodate a life-support system and a spacesuited crew, one of the seats was removed and Soyuz flew as a two-man spacecraft for the remainder of its life, ending with Soyuz 40 in 1981.[13]

Prior to this, unmanned flights in the Cosmos series, having characteristics similar to those of manned missions, pointed to the development of a new manned spacecraft.[14] It was mildly disappointing when, on its first flight to the Salyut 6 space station at the end of 1979, it was named Soyuz T and then shown in photographs to have the same external shape and dimensions of the old Soyuz.[15] Internal redesign has restored the three-man capacity,[16] whilst permitting the use of spacesuits at critical phases of the mission, and an onboard computer has enhanced its performance. Whereas the early Soyuz spacecraft were stated to have a 30-day capability, Soyuz T 5 functioned in orbit for 106 days, during which it was docked with Salyut 7 for 103 days.[17]

A major disadvantage of using the Soyuz appears to be the tight constraint imposed by lighting conditions during recovery. Information released at the time of the Apollo-Soyuz Test Project (ASTP) revealed that landings should occur at least 1 hour before local sunset and that a minimum of 8 minutes should elapse between eclipse-exit and retrofire. Graphical analyses by Christy[18] and Clark[19] show that the 31 revolutions repeating pattern of ground tracks employed for the Salyuts 6 and 7 lead to landing "windows" at intervals of approximately 2 months. Moreover, the duration of these windows varies from only 7 to 10 days depending on the time of year. These windows, in turn, impose constraints on mission durations. The 8-day Intercosmos missions, for example, were launched immediately prior to the opening of a landing window so that, if the need to abort prematurely should arise, as with the Bulgarian mission, the constraints could be obeyed on the third day.[20] To date, Soyuz T spacecraft have also obeyed these constraints and have yet to demonstrate the capability to make normal landings at any time of the day or night. If this practice is followed for Berezovoi and Lebedev, then the next window opening around the end of the year would prolong their mission to something in excess of 230 days.[21] The constraints could be obeyed in an emergency at other times of the year by moving the recovery zone from the Kazakhstan region. Cosmonauts have been depicted training for recovery from landings in water should such landings prove to be necessary.[22]

Up to a few years ago, the orbital module remained attached to the command module until after retrofire.

Latterly, it has been jettisoned prior to retrofire.[23] The orbital module, filled with bulky, used equipment, burns in the atmosphere on reentry and provides a means for disposing of unwanted material as an alternative to the regular use of the airlocks. The unloaded Progress performs a similar function but is deorbited over the Pacific rather than being left to decay naturally. The crew capacity of the Soyuz T is limited to three by the use of the A-2 vehicle for its launch. This booster, using the same first stage as that used to launch the first Sputnik 25 years ago, is the only Soviet booster to be man-rated to date. The large D vehicle now appears to be totally reliable and could possibly be man-rated at some future date for launching spacecraft with larger crew complements, and some Western observers speculate that the mysterious dual payload launches at 51.6° inclination were reentry tests of reusable winged spacecraft.[24] The Cosmos 1374 mission of summer 1982 has been claimed to have been a reentry test of a scale model winged spacecraft, launched by the intermediate capacity C vehicle; the Royal Australian Air Force released pictures of the follow-on Cosmos 1445 spacecraft being recovered from the Indian Ocean.[25] Nevertheless it is not unreasonable to suppose that research and development work leading to a reusable manned spacecraft to service a permanently manned space station is in hand.

The unmanned Progress craft is something more than an interim measure to provide space-station crews with fresh supplies. The Soviets have mastered the technique for resupplying their Salyut stations with propellant and potable water, a feat unmatched in the Skylab missions and, as yet, unnecessary for the space Shuttle. Moreover, the residual propellant of the Progress engine has been used to maneuver the Soyuz-Salyut-Progress orbital complex in the manner of a primitive space tug.[26]

The altitudes selected for the Salyut missions below the Van Allen radiation belts[27] are not the most economical in terms of propellant usage. The relatively high air-drag, particularly in the case of the "military" Salyuts 3 and 5,[28] made great demands on stored propellants to maintain the orbit throughout the duration of the missions. Choice of a greater altitude to minimize propellant consumption exacts a penalty in terms of surface resolution for Earth observation programs. As space stations increase in physical size and complexity the drag problem will attain an even greater significance.

The small interior volume of the Salyut stations, which have an effective floor-area of 16 square meters[29] in the working compartment, must lead to cramped conditions, especially at times when the cosmonauts are joined by visiting crews. A first step towards increasing the interior volume came with the docking of Cosmos 1267, a "prototype space module,"[30] with Salyut 6. Although this docked complex was never manned, it was claimed[31] that future stations could be enlarged by docking with modules dedicated to different disciplines including crew rest and relaxation. The Cosmos 1267 engine was used to maintain the Salyut 6 orbit[32] and eventually to deorbit the docked complex at the close of the joint mission.[33] Cosmos 1267 and its predecessor, Cosmos 929, were both reported to have returned part of their structure to Earth after a period of some 30 days.[34] Salyuts 3 and 5 also returned capsules during the unmanned phases of their missions, and thus an unmanned return capability already can be seen to exist.[35]

Another disadvantage of the current Salyut program is the lack of near-continuous communication with ground stations. For long periods in each orbit the crew is out of touch with ground control. In the initial stage of Soviet manned spaceflight this disadvantage was partially overcome by the use of shortwave frequencies for voice communication as well as the long-range housekeeping telemetry still in use today. Later, merchant ships were converted to provide communication links through Molniya satellites,[36] and purpose-built vessels have since modernized the space support fleet maintained by the U.S.S.R. Academy of Sciences.[37]

Details of an Eastern Satellite Data Relay Network (ESDRN) lodged with the International Frequency Registration Board in 1981[38] show that the Soviet Union intends to operate a system employing frequencies in the Ku-band[39] similar to the American TDRSS for communicating with Salyut stations and other spacecraft in low-Earth orbit, commencing no sooner than December 1985.

Following the end of the manned phase of the Salyut 6 mission in 1980, articles appeared in the daily and technical press detailing the achievements and outlining future needs.[40] Isvestiya stressed that those achievements were not only in the great reliability and longevity in space of the onboard systems and equipment but also in the vast amount of experimental work aimed at finding solutions for fundamental scientific problems and practical requirements on Earth today. The requirements of 22 of the Ministries and Departments of the U.S.S.R. were considered.

More than 1,600 experiments were said to have been performed involving some 150 items, many of which were repeated at least once.[41] Of these, 60 were astrophysical, 200 on the production of materials of exceptionally high purity, and 900 in medicine and biology. Many of the latter were in cooperation with other countries as part of the Intercosmos program. The superpure materials ranged from the homogenous alloys and semiconductor materials, produced in the Kristall, Splav, and Isparitel furnaces and ovens,[42] to vaccines produced by electrophoresis.[43] Much time was devoted to the observation of the Earth from space. Some 13,000 photographs were obtained using the Kate-140 topographical and MKF-6M multispectral cameras.[44] As a result, a supply of freshwater was located in the Kyzyl-Kum desert and large-scale geological features coinciding with mineral deposits and possible oil-bearing regions were identified.[45] It was stated that photographs of an area covering 1 million km² could be recorded on film in 10 minutes, equivalent to the result of several years' aerial photography.[46] (Salyut 4 was reported to have returned photographs of 4.5 million km² of the U.S.S.R.)[47] In addition to radioastronomy, experiments with the KRT-10 in 1979,[48] astronomical observations of active areas of the Sun's surface and other X-ray sources were made and infrared radiation from the planets and stars was recorded using the cryogenically cooled 1.5-meter diameter BST-1M telescope.[49] For these observations an orientation accuracy of a few arc seconds was maintained,[50] and some Western commentators have seen military implications related to the pointing of directed-energy weapons in this context.[51] Undoubtedly, there is a large area in which military and scientific experimental programs overlap each other.

Experience has shown that it is possible for crews to work in space for long periods at a time so long as they follow a regular exercise regime[52] to counteract the effects of prolonged weightlessness. Equally important is sustaining the psychological well-being of the crew.[53] To this end consideration has been given to the interior decoration of the station.[54] It was found that working to a normal Earth time schedule was beneficial both to the cosmonauts and the ground-support teams. Regular rest days at weekends are used for housekeeping and relaxation. The introduction of a two-way television link[55] enabling the cosmonauts to see their families whilst talking to them at the weekends was a great morale-booster as were the visits from short-term crews. However, the strain began to tell on the Salyut 7 cosmonauts who set the record of 211 days in space, and their working day was reduced from 16 to 12 hours.[56]

And what of the future? Steps must be taken to overcome the disadvantages of the current program mentioned above. More efficient transport crafts are needed. A Soyuz can deliver only 50 kg of supplies in addition to its crew, and Progress is limited to 2,300 kg.[57] Although Progress transports delivered more than 20 tonnes of supplies to Salyut 6 in 12 visits, the greater part of the cargo comprised life-support system supplies and units, fuel and replacements for onboard systems.[58] A man requires more than 10 kg of replacement life-support system elements every day,[59] and

there is an obvious need to change over to a new life-support system operating on a closed cycle, thereby eliminating the need to deliver water and atmospheric purification supplies. (A water-regeneration system did not produce in excess of 500 liters of potable water on Salyut 6.)[60] A reduction in the amount of fuel necessary for station orientation could be effected by the adoption of an electromechanical orientation system.[61] (Trials of this type of system were conducted on Salyut 3 and must be presumed to have been less than satisfactory since this principle has yet to be adopted operationally.)

The introduction of a new onboard computer system for Salyut 7 has relieved the crew of much routine work connected with the operation of the station.[62] This is markedly noticeable in communication sessions with ground control. On previous missions much time was spent in calling "Zaria," the ground control, in order to confirm that two-way contact had been established. Today, the computer switches on the transmitter when the stations rises above the radio horizon of the ground station, and the cosmonauts speak from wherever they chance to be in the station at the time. Feoktistov, commenting on the introduction of computer and microprocessor technology, has cautioned that enthusiasm for automation can lead to extraordinary complexity and, consequently, a reduction of equipment reliability.[63]

The elimination of the need to mothball the station between periods of occupancy by long-term crews would be a logical step in the steady evolution of Salyut operations. A further improvement would be the provision of facilities for receiving water and propellant from Progress transports at either of the two docking ports. This would eliminate the transportation and redocking which has hitherto been necessary to relocate the Soyuz at the forward docking port in order to accommodate a Progress at the aft port. Such redesign may also encompass provision of nonaxial docking ports although destruction of axial symmetry could introduce problems in maneuvering and altitude control.

In the distant future one might expect the Soviets to take steps to establish a permanent space station in geosynchronous orbit[64] for the collection of solar energy, its conversion to electrical energy, and transmission to Earth by microwaves, but these possibilities introduce difficulties several orders of magnitude greater than those solved to date.

SOVIET SPACE ACTIVITIES: IMPACT ON U.S. SPACE POLICY

by Marcia S. Smith

The Reagan Administration, like that of President Carter, is conducting a review of U.S. space policy for both the civilian and military programs. One facet of U.S. space policy that has received little mention is the role of Soviet space activities in shaping U.S. programs. After all, it was the Soviet lead in space that propelled the United States into the space age and led to the writing of the 1958 National Aeronautics and Space Act. The spaceflight of Yuri Gagarin in April 1961 was an important factor in convincing President Kennedy to choose the space program as a vehicle for restoring confidence in American technological leadership—and led to the Apollo lunar program.

What, then, is the Soviet Union doing in space today?

Are they likely to confront us with a space spectacular on the order of Sputnik or Vostok I, and would it make any difference this time?

This is a brief review of current Soviet space activities and plans for the future (since they rarely announce their plans in advance, discussions of future activities must be considered speculative). It focuses on Soviet space activities as they might impact American space policy, so the discussion centers on issues that are likely to receive the most scrutiny in the United States this year: manned activities, planetary programs, and military activities. Space applications programs are not discussed because the primary U.S. issue in this area is whether government or private industry should be responsible for these programs—an issue that has no counterpart in the Soviet Union. The Soviets do not separate their space program into military and civilian components, so the question of combining such activities in the United States is also omitted.

MANNED SPACE ACTIVITIES

The early Soviet manned program was much like that of the United States. The Soviet Vostok program was similar to U.S. Mercury flights, and Voskhod and early Soyuz flights were roughly comparable to Gemini. A sad similarity between the programs was the tragic blows dealt to both countries in 1967. In January, the three-man crew of Apollo I was killed in a pre-launch fire; in April, the single occupant of Soyuz I was killed on impact with the earth when the parachute lines on his spacecraft became tangled during descent.

The 1960's was the era of the infamous "Moon Race", and when the two manned programs began again in October 1968, it was clear that the U.S. was in the lead. The first manned U.S. mission (Apollo 7) tested the Apollo command/service module in earth orbit, while the first Soviet mission was an orbital rendezvous between one manned and one unmanned ship, a feat accomplished by the Americans three years earlier. The race was won two months later when the Apollo 8 crew circumnavigated the Moon, followed seven months later by the first lunar landing. The Soviets turned their attention to Earth orbit.

Space Stations

A popular topic of conversation today is whether the United States should build a space station as its next major manned space activity. The Soviets already have such a program, and have stated that their goal is to have a permanently occupied earth orbiting space station. They are well on their way to achieving that goal.

In 1971, the Soviets launched the world's first space station, Salyut 1. Since that time, six more Soviet space stations have been launched—four successfully. With each new station, new capabilities have been achieved. Three of the stations are classed as military, while the other four are considered to be civilian. The difference between the two modes of operation is that military space stations use military frequencies for communications, have only military personnel for crews, and are in lower orbits to facilitate reconnaissance activities. The civilian stations use civilian frequencies, mixed military/civilian crews, and are in higher orbits which allow earth resources photography as well as astronomical observations. A wide range of biological, materials processing, and other experiments are performed as well. In total, the Soviets have sent 28 crews to occupy the space stations (22 successfully).

This program has not been without its troubles and tragedies. The first crew sent to inhabit Salyut 1, Soyuz 10, docked successfully, but was unable to enter the space station because the hatch could not be opened. The Soyuz 11 crew successfully inhabited the station for 24 days, but died from asphyxiation during reentry when an improperly closed hatch on the Soyuz spacecraft allowed the cabin atmosphere to vent into space. The crew was not required to wear spacesuits. Since that time, cosmonauts have worn suits during launch and reentry, forcing a return to two-man crews because the Soyuz could not accommodate three men plus the bulky suits and associated systems. Ten years were required before a modified version of Soyuz appeared, which together with new spacesuits, could accommodate three-man crews again. Five more of the crews sent to space stations did not dock successfully.

The statistics which the Soviets have accumulated recently in manned spaceflight are impressive, especially when compared with U.S. manned space activity. The last U.S. flight of the Apollo era was the July 1975 Apollo-Soyuz Test Project, a cooperative project with the Soviet Union. At the conclusion of ASTP, the U.S. had a cumulative total of 22,504 hours in space, while the Soviets had 10,740 hours. There were no more U.S. manned flights until the April 1981 flight of Space Shuttle Columbia

—a six year hiatus. During that time, the Soviets made 21 manned flights (18 of which were successful), all but one of which ferried crews to space stations. The 84-day duration record of Skylab 4 was broken by the Soviets in 1977 with the 96-day mission of Soyuz 26, and was successively increased to a duration of 185 days by the Soyuz 35 crew in 1980. From April to December 1981, the U.S. made two flights of the Space Shuttle and the Soviets made one more flight to a space station. By the end of 1981, the cumulative hours in space were: U.S.—22,721 hours; USSR—51,233 hours.

One of the greatest successes of the Soviet space station program is Salyut 6. Launched in September 1977, the station is still in orbit and functioning as of February 1982. The most significant improvement on Salyut 6 is its second operational docking port which allows two spaceships to dock with the station at one time. As a result, the ferry ship for the crew can remain docked at one end, while ships carrying supplies or additional crews dock at the other. With Salyut 6, the Soviets have demonstrated in-flight refueling, and the use of a second vehicle to boost Salyut's orbit, thus extending its lifetime. The Soviets have also docked second crews for visits with the long duration crews, both to bring supplies and to relieve the boredom. Nine of these flights have orbited representatives of the Interkosmos countries (Czechoslovakia, Poland, East Germany, Bulgaria, Hungary, Vietnam, Cuba, Mongolia, and Romania, in that order).

Salyut 6 has not been used for permanent occupancy yet, but that is possible. The Soviets may wait for Salyut 7, though, which is expected to be launched in 1982 and is planned to host a joint Soviet/French crew. Salyut 7 is rumored to be the first of a "modular" space station series which will have several docking ports, to which individual modules will be attached in orbit. In June 1981, the Soviets docked Kosmos 1267 with Salyut 6 and announced that it was a test of this modular concept, although since that time there have been unconfirmed reports in the Western press that Kosmos 1267 is in fact a "space battle station" armed with infrared homing devices. Kosmos 1267 remained docked to Salyut 6 as of February 1982.

Soviet Space Shuttle

Rumors of the imminent appearance of a Soviet version of a reusable space vehicle have been prevalent for at least the past five years. Several Kosmos flights made in the mid- and late-1970's are thought by some Western analysts to have been tests associated with such a vehicle, and there also have been unconfirmed reports that the vehicle has been drop tested from aircraft (similar to the approach and landing tests for the U.S. Shuttle).

While there is no way to definitively determine from unclassified sources whether or not the Soviets are in fact developing such a vehicle, the issue can be discussed in terms of the utility of a reusable vehicle and its likely characteristics. The Soviets have stated their intention to have permanent Earth orbiting space stations, so it would be logical for them to develop a reusable vehicle for ferrying crews back and forth. Since they already have space stations, and seem to have an adequate supply of expendable launch vehicles (ELVs) for orbiting other satellites, it seems unlikely that they would include a cargo bay like that on the U.S. Space Shuttle. An analogy has been drawn by some Western analysts between the rumored Soviet vehicle and the U.S. Dyna-Soar, which was cancelled in 1962 for budget reasons. Essentially, the design is that of a very small reusable vehicle launched by an ELV.

The only clues as to whether such a vehicle is under development are statements by people associated with the Soviet space programs, for example, the cosmonauts. Their most recent statements regarding a Soviet shuttle is that such a system is "not economical at this time". The Soviets have also recently upgraded the Soyuz spacecraft (it is now designated Soyuz-T), possibly indicating that they are not going to introduce an entirely new system in the near future. Thus, one could conclude that it is logical that the Soviets are developing a reusable vehicle, smaller that the U.S. Shuttle, but it is not likely to be introduced for several years.

The Soviet Super-Booster

No discussion of the Soviet manned space program would be complete without mention of the legendary "super-booster" which was rumored to be under development in the 1960's. Often referred to as the "G" vehicle, it was expected to be comparable in thrust to the U.S. Saturn V which sent astronauts to the Moon. The largest existing Soviet booster, the "D" vehicle, is roughly comparable to a Saturn IB, and has never been man-rated.

In the late 1960's, there were

(continued on page 23)

widespread rumors that the Soviets had attempted three test launches of the G vehicle, all failures. One allegedly killed several leading Soviet spacecraft designers. The lack of a booster of the capability of Saturn V is sometimes credited as the reason the Soviets have never sent men to the Moon, although such a mission could have been accomplished in other ways.

Very little was said about the G vehicle during the 1970's, although rumors of its existence and "imminent" testing have never died. In 1981, the United States published a booklet entitled "Soviet Military Power" which referred to Soviet development of a booster resembling the G vehicle, which served to rekindle the somewhat dormant issue. As with the debate over a Soviet shuttle, there is no way to determine from open sources what the status of the G vehicle is, but the question can be considered from the viewpoint of what utility such a vehicle would have for the Soviets.

A large vehicle would be useful for launching large space stations, for launching other large payloads such as weapon systems, or for manned lunar or planetary flights. The Soviets have indicated that their approach to large space stations will be constructing them from modules in orbit, so a large vehicle would not be necessary for this purpose. Similarly, other large systems could be constructed in orbit, although the ability to launch an entire weapon system with one vehicle would give the Soviets a quick response capability. The Soviets have stated that one reason they are interested in extending the duration of flight for crew members is because they plan to send crews to Mars in the future. Manned planetary flights or flights to the Moon (which still may be a Soviet goal), could be accomplished through earth-orbital assembly of appropriate vehicles, an approach that was considered by the United States in the early 1960's (the lunar orbit rendezvous method was finally chosen instead). A Saturn V sized vehicle would make these tasks easier, however.

In summary, there are several probable programs that could benefit from a G vehicle, but none that apparently require it. The question of whether such a vehicle is under development is more problematical than the shuttle.

PLANETARY PROGRAMS

A great deal of concern has been voiced in the United States recently about the "death" of the U.S. planetary program. Since the beginning of the space age, U.S. probes have visited Mercury, Venus, the Moon, Mars, Jupiter and Saturn, and one is now enroute to Uranus and Neptune. By contrast, the Soviets have sent probes only to Venus, the Moon, and Mars. With Venus and the Moon, they have been very successful. Mars, on the other hand, has eluded their grasp so far.

Soviet probes made the first hard landing and the first soft landing on Venus, and in 1975, Venera 9 and 10 sent back the first photographs of the Venusian surface. Venera 13 and 14

(continued on page 34)

Soviet Space Activities

(continued from page 23)

were launched by the Soviets in late 1981, and should reach the planet in March 1982. The Soviets also launched the first probe to reach the Moon, and to send back pictures of the far side. As noted previously, they have also used unmanned probes to return samples of lunar material to Earth, and have sent two Lunokhod roving vehicles to the Moon for on-site observations and chemical analyses. The Soviets have admitted to launching seven probes to Mars (there are other suspected failures in the early 1960's). Several of the probes missed the planet entirely, and those which did reach the planet ceased transmitting at critical times in the mission (one 20 seconds after the probe reached the surface; the other, just before it would have landed).

For the future, it appears that the Soviets are content with doing what they do best – continued studies of Venus. The Moon seems to have lost its appeal (as in the United States), and no Mars attempts have been made since 1973. The next Venus opportunity will be in 1984, and the Soviets are planning a dual mission for that time period. After the two landers are dropped off at Venus, the two fly-by probes will continue on to an intercept with Halley's Comet. The Soviets are establishing an agreement with the European Space Agency and Japan, both of which are also sending probes to the comet, for sharing data from the missions.

MILITARY SPACE ACTIVITIES

The Soviet Union launches satellites at an annual rate several times that of the United States. In 1981, the Soviets made 98 successful launches, compared with 18 for the United States. Although the Soviets do have a more active space program in general, some of the discrepancy in the statistics is due to the number of military launches they make—approximately two-thirds of the launch total in a given year. This is partially caused by the relatively unsophisticated technology of their reconnaissance satellites, which require more frequent replacement than their U.S. counterparts. In addition, most U.S. military communication needs are met by a few satellites in geostationary orbit (GEO), while the Soviets make use of several different types of military communication satellites in non-GEO orbits (they do not use GEO to the extent other nations do—their first GEO satellite was not launched until 1974, 11 years later than the United States).

Military space activities of the two countries are roughly comparable with three major exceptions: the Fractional Orbital Bombardment System (FOBS), antisatellite (ASATs), and radar ocean surveillance satellites. FOBS is essentially an extended range ballistic missile which would permit the Soviets to send warheads to the United States by a trajectory over the South Pole, thus avoiding the Ballistic Missile Early Warning System radars which point to the north.

ASATs are devices which destroy other satellites. The Soviets have made 19 tests of their ground-based ASAT system since 1968, and in 1977, the U.S. Secretary of Defense termed the system operational. The Soviet system involves the launching of a satellite into an orbit close to that of the target satellite. The interceptor maneuvers close to the target and explodes, thus disabling the target with shrapnel. The United States is currently developing an air-launched ASAT system, but it is not expected to be operational until the mid-1980's.

The Soviets have launched radar ocean surveillance satellites since 1967, which provide an advantage over U.S. reconnaissance activities in that the powerful radars permit reconnaissance of U.S. fleet movements even in clouds or darkness. The radars are powered by nuclear reactors, and the unexpected reentry of one of these satellites in 1978 created international concern when radioactive debris was spread over northern Canada. Despite continuing debate at the United Nations over whether reactors should be allowed in space, the Soviets resumed launches of these satellites in 1980.

There have been many rumors that the Soviets are developing directed energy weapons (lasers and particle beams) for use in space either against satellites, or against targets on the planet or in the air. As mentioned previously, there have been reports that Kosmos 1267 is a battle station equipped with infrared homing interceptors. None of these reports has been confirmed.

CONCLUSION

The answer to the question, "will the Soviets confront us with a space spectacular" in the near future depends on the definition of spectacular. It seems very likely that the Soviets will have a permanently occupied space station within the next year or two. Less likely, but not impossible, would be the appearance of a Soviet reusable space vehicle before 1984 or 1985, or the launch of the G vehicle. The Soviets do not appear to be readying anything extraordinary in the planetary arena, although they may gain some international prestige with their Halley's Comet mission.

Militarily, it is possible that a new ASAT system will appear in the next several years, although whether it will be a directed energy weapon or not remains questionable. The Soviets have introduced a treaty at the United Nations to ban weapons from space, but without such a treaty there is nothing to stop either side from developing new non-nucleur systems, and it is unlikely that the treaty will be successfully negotiated soon. (The use of nucleur weapons in space is already prohibited by treaty).

A spectacular Soviet accomplishment in space might serve to push the United States into developing a coherent space policy and specific goals in order to regain leadership in this arena. On the other hand, it may have no impact at all. The accomplishments of the Soviets over the past six years with the space station program are relatively unknown in the United States outside of the space community, even though an event such as refueling Salyut 6 in orbit might have qualified as a highly significant event. These activities have had no discernible impact on U.S. policy. ★

Future Soviet Space Plans Unveiled

A USSR version of the American Space Shuttle will be flying in five years and a Soviet manned Mars mission may be practical within 10 to 15 years, states Soviet Embassy Attache for Science and Technology, Anatoliy Y. Skripko.

Speaking at a February luncheon of the American Astronautical Society (AAS) in Washington, Skripko told the gathering that a third generation Salyut space station is to appear "in the not too distant future", yielding greater volume and carrying new automatic systems. Such systems will free cosmonaut time to conduct increasing amounts of non-automated space experimentation. The Soviet attache stressed the fact that his country's space engineers are "searching for methods to raise space station efficiency".

Skripko noted the highly successful work of the 27 cosmonauts who have resided in the Salyut-6 orbiting laboratory. Crews have conducted 1,600 experiments, with over 300 materials processing samples obtained using a furnace aboard the high-flying lab. Some 9,000 images of the Earth have also been returned to assist in resource detection and monitoring.

Now in an unmanned mode, Salyut-6 has whirled around the globe since 1977 and "on the whole, could be reused", although the station's electric-generating capacity is dwindling, explained Skripko. In addition, Salyut's windows are covered by dust, hampering Earth and astronomical observations. Space-walking cosmonauts have failed to remove the debris from the windows. Special porthole covers are being designed to be flown on future stations, added Skripko. A decision on whether cosmonauts will revisit Salyut-6 or fly to a yet-to-be-lofted Salyut-7 is expected in 3 to 4 months.

Salyut-6 has demonstrated, stated the attache, that no biological limitations exist to bar long duration space flight by humans. Both the 175 and 185-day marathon flights by cosmonauts, housed in the Salyut-6, show calcium loss levels of about 8%, with 16% calcium loss considered acceptable on Earth. Cosmonauts on these missions returned to Earth with a new composition of red blood cells; the life span of such cells is normally 120 days. Once the cosmonauts readapted to Earth's gravity, the altered cells were replaced by Earth-born cells. "In 10 to 15 years, any person in good health will be able to fly in space. This has been proven by results from our Salyut," said Skripko.

FUTURE DIRECTIONS

As for Soviet space programs in the future, the science representative stated impending Salyut stations will be comprised of many modules: astronomical, technical experiment, and physical and chemical experiment modules. These laboratories can house "large collectives", rather than single crews in near-Earth space, functioning for several years.

The long awaited Soviet space shuttle is not needed at this time, explained Skripko, as expendable spacecraft are now produced in inexpensive quantities. However, a near term goal of Soviet space planners is to provide transportation into orbit at a cost of 25 roubles per kilogram, a translated figure ten times less than projected by using the U.S. space shuttle. Within 5 years a Soviet shuttle may be operating, with "more detailed news" coming in 2 to 3 years, Skripko told the AAS audience.

Soviet scientists have outlined an ambitious space exploration program in several areas: studies of the Sun's relationship with Earth and global climate; continued study of Venus with "aerostats" unleashed in the Venusian atmosphere; comet exploration; and extraterrestrial astronomy utilizing large telescopes. Improved propulsion systems, such as nucleur, ion and plasma engines, are also under study according to Skripko.

The embassy official commented that Salyut stations took the first step toward long-term astronomical observatories. Soviet planners are currently investigating thermal characteristics of future orbiting telescopes, built to carry mirrors of "several meters" diameter in the next decade.

Soviet planetary exploration is to be furthered by unmanned robots, perhaps controlled by artificial intelligence. Such robots, Skripko stated, could pave the way for eventual human expedition to Mars within 10 to 15 years time.

Skripko suggested that, even though the U.S. and the Soviet Union have followed separate space paths, common interests in planetary research, space medicine and biology could be furthered by international cooperation. The Soviet/American political climate, however, makes joint cooperation "difficult, if not impossible," added the Soviet attache. ★

Arianespace Markets Launch Service

By Jeffrey M. Lenorovitz

PP 87, 90-91, 93, 95.

(c) Aviation week & space technology, McGraw-Hill, Inc.

Evry, France—Successful entry of Europe's Ariane launch vehicle into worldwide satellite launch services competition has been aided by the private Arianespace organization, which was formed to sell the system to prospective payload customers.

This operation has been credited with much of the market penetration logged by the Europeans during their initial sales promotion efforts. Europe's approach to launch service sales differs from that in the U.S., where the federal government has direct involvement in payload bookings for American launchers. U.S. operations, therefore, are not as marketing-oriented as the European competition.

Technical Gains

Arianespace's sales efforts have been enhanced by technical successes achieved in the final two missions of the four-flight Ariane test program. These launches last June and December helped remove the doubts about Ariane's capability that were raised by the failure of the second test launch in May, 1980.

Completion of the four-flight Ariane test series last Dec. 19, which included the orbiting of the Marecs maritime communications satellite, moved the European launcher system into its operational phase. The program's overall pace is continuing to accelerate. Besides the increased sales efforts, development of the follow-on Ariane 2 and 3 versions is continuing. European approval also is nearing for the Ariane 4 configuration that ultimately will boost the vehicle's lift capacity to 4,000 kg. (8,800 lb.) for geostationary orbit.

The achievements of the last two test launchers, combined with the Arianespace sales progress and the plans for expanding the Ariane family through the fourth launcher derivative, have positioned Ariane as a serious competitor for a range of payload launch customers, including those being sought by the U.S. space shuttle. Arianespace officials said sales of launch slots to the U.S. and other countries have shown the launcher's viability.

"I think we have shown Ariane is not merely a European launcher. We, of course, can rely on certain orders from France and the European Space Agency, but we have demonstrated through our sales that Ariane is viable in other regions," an Arianespace manager said.

Launch vehicle capabilities also are being developed in other countries. These include the Japanese H-1 program, India's expanding family of launchers and a program just beginning in Brazil. The sales potential of these launch vehicles depends on financial resources and technical successes gained in the programs, as well as on the individual nations' policies toward marketing the systems outside their home countries.

The USSR is continuing large-scale launch vehicle efforts, and the People's Republic of China is advancing into launcher development. Neither has emerged as a competitor on a commercial level.

Several U.S. industry officials have stressed the importance of Europe's decision to separate Ariane marketing operations from direct governmental involvement. "What Arianespace has that we in the U.S. do not is the flexibility of a pure marketing force. The organization's goal is to sell the launcher, and it can function differently than if it were directly tied to the government, as is the case in the U.S.," a U.S. space official said.

"Perhaps we can learn something about the way the French, who are the leading force in Arianespace, are handling their marketing."

Many industry officials agree that Europe's Ariane successes in the world market have stemmed from the merging of several key elements:

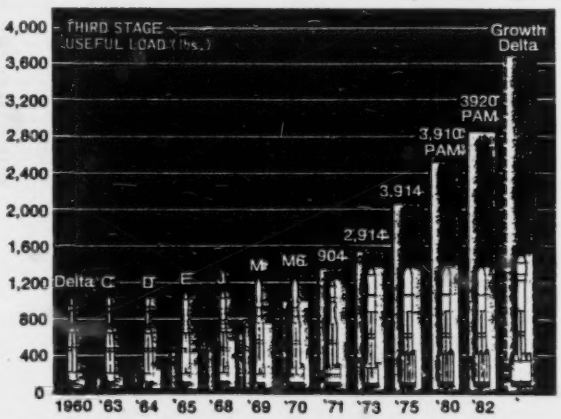
- Continuing improvements in Europe's technology base as well as maturing production techniques.
- Capability of European nations to work efficiently together on multinational programs and to establish coordinated management functions.
- The emergence of European overall marketing capability, particularly in France.

The technology developed in the 1960s was refined in the 1970s as aerospace industries in western Europe evolved expertise in key areas. The pluses and minuses of advanced-technology applications also were considered more carefully during the years of the Ariane's development. For example, it was decided to rely largely on state-of-the-art technology as the basis for Ariane's development rather than to make broad steps into unproved areas, French officials said.

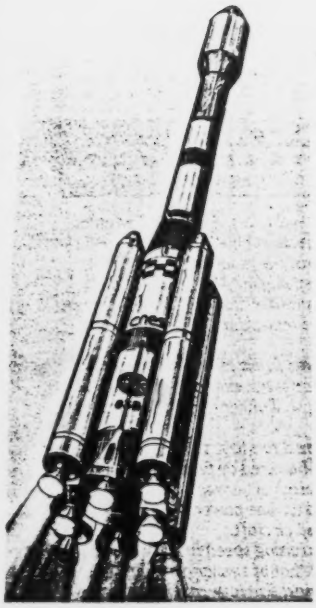
'Route Proved'

"Rather than use technology for technology's sake, we took a more proved route for Ariane," an executive at the French national space agency CNES (Centre National d'Etudes Spatiales) said. "We wanted to develop a reliable and producible system, and decided this was the best approach." As important as technical capability is the improving capacity of European countries to work together on multinational programs.

The improved working relationships



U.S. Delta launcher family, produced by McDonnell Douglas Astronautics Corp., has expanded from its initial configuration in the 1960s to proposed growth versions capable of orbiting payloads that weigh up to 3,000 lb. The vehicle's upgrades are achieved through a variety of methods, including the use of the payload assist module (PAM).



among Europe's aerospace industries is well illustrated by the multinational Airbus Industrie consortium, whose A300/A310 transport aircraft program involves the participation of France, Great Britain, Germany, Spain, Holland and Belgium.

A centralized headquarters is located at Toulouse, France, where the assembly line integrates components produced by the participating countries. The consortium has been able to increase its output significantly.

A production rate of 4.2 aircraft per month is expected to increase to eight per month in 1984. Acceleration of the production rate will allow Airbus to keep pace with the growing sales volume for its twin-engined A300 family.

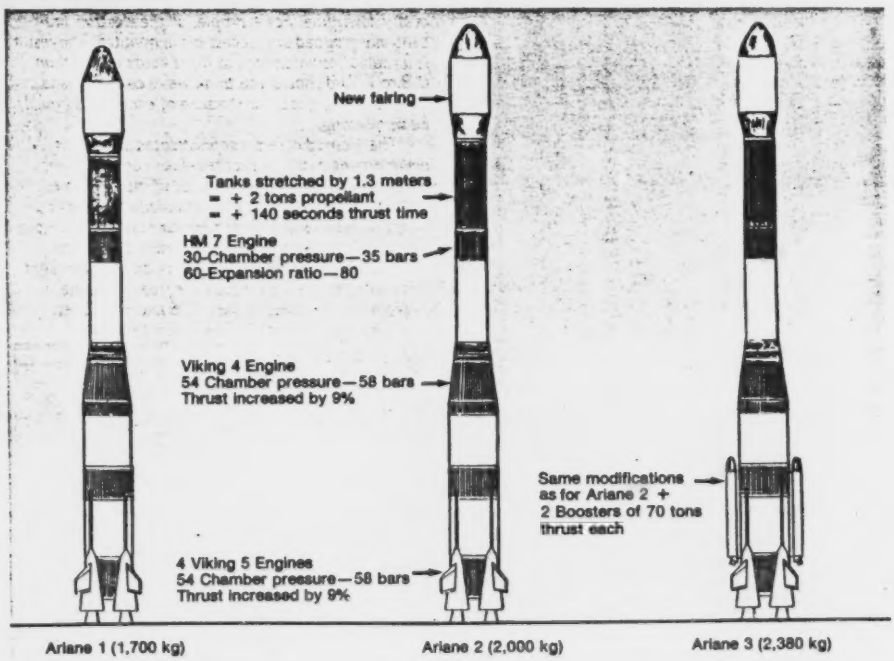
"Although the Ariane launcher and A300 transport are not exactly the same type of product, they both represent current aerospace technology and are examples of successes we in Europe are realizing as the result of working together," a Germany industry executive said.

Another element in Europe's commercial aerospace advances is the maturing of marketing techniques among European sales forces. Some of the earlier shortcomings in sales approaches to non-European nations have been resolved, and such innovations as the formation of the Arianespace organization have materialized.

Arianespace was formed in 1980 to handle the industrial management of Ariane, plus the marketing of launch services, control of launch operations at the Guiana Space Center and financing of launcher production.

It is a private company with support from the governments of participating nations and the backing of several European banks. Shareholders include government agencies such as France's CNES; companies involved in Ariane pro-

Configurations of three international expendable launcher systems are shown. The European multinational Ariane program has evolved three specific versions (below) and the development of a fourth is nearing approval by the participating nations (left). The basic Ariane 1 has been used in the initial launch series and is capable of placing 1,700-kg. (3,740-lb.) payloads in geostationary transfer orbits, while the follow-on Ariane 2 and 3 derivatives increase the capability to 2,000 kg. (4,409 lb.) and 2,380 kg. (5,247 lb.), respectively. The proposed Ariane 4 would be capable of placing 4,000-kg. (8,800-lb.) payloads into geostationary orbit in the heavyweight version equipped with four liquid strap-on boosters.



duction such as France's Aerospatiale, West Germany's Dornier, Messerschmitt-Boelkow-Blohm and ERNO, and Spain's CASA, and banking organizations ranging from the French Credit Lyonnais to Germany's Dresdnerbank and Italy's Istituto Bancario San Paolo di Torino.

Total shares are distributed among sources in the 11 involved countries, with France holding the largest share at 59.25%. The other share distributions include 19.6% in Germany, 4.4% in Belgium, 3.6% among Italian organizations, 2.7% in Switzerland, 2.5% in Spain, 2.4% each in Great Britain and Sweden, 2.2% with Dutch shareholders, 0.25% in Ireland and 0.70% among Danish shareholders.

Although Arianespace was established separately from the French government, it is able to derive key benefits from its close ties to French national research and technology agencies and with its aerospace industry. This relationship is evidenced by the location of Arianespace at the CNES facility here at Evry outside Paris.

"The way the French national space agency CNES nurtured Arianespace has provided a strong foundation for the marketing organization. It is able to transition promising personnel to the Arianespace marketing group and provide invaluable support, and in this manner strengthen the overall effectiveness of the marketing operation," one European-based U.S. industry representative said.

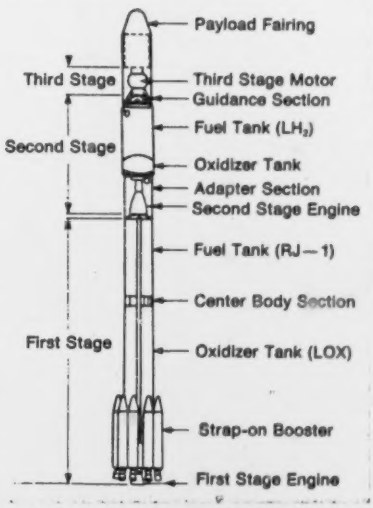
As Arianespace seeks to increase its sales in the world market, launcher capabilities also are emerging from several locations outside Europe and the U.S. India is one such country that is working to develop its launch vehicle program as well as the capability to build spacecraft for its telecommunications and other needs. India's technological advances have been derived in part from its close ties with Europe and the U.S.

India has been able to train its personnel in the U.S., Europe and elsewhere, and it has had direct infusions of technology through these worldwide connections. Approximately 50 Indian engineers have been involved in Ariane work at CNES and at France's propulsion company SEP (Societe Europeenne de Propulsion), and France helped India develop its SLV-3 launcher.

India's Apple communications satellite, which was built with technological help from other countries, was orbited on the successful third Ariane test flight in June, 1981, and it is continuing its operations despite some initial on-board problems (AWAST Sept. 14, 1981, p. 19).

India plans to improve the capability of its own launch vehicle from 50 kg. (110 lb.) to about 150 kg. (330 lb.) during the next few years. Beyond this, the country's space agency ISRO (Indian Space Research Organization) is examining a significantly larger vehicle that could orbit 600-700-kg. (1,320-1,540-lb.) payloads. The larger vehicle could be a four-stage solid/liquid-fueled launcher.

Japan is increasing its launcher family. The next step is represented by the National Space Development Agency's H-1 vehicle, capable of placing 550-kg. (1,210-lb.) payloads in geostationary orbit. Flight tests of a two-stage version are scheduled in 1986, and the three-stage configuration will be tested in 1987.



Japan is developing a new launcher that is expected to be capable of carrying 550 kg. (1,210 lb.) payloads into geostationary orbit. The three-stage H-1 launcher is under development by the National Space Development Agency (NASDA), and it is expected to meet the need for launching of heavier applications satellites for Japanese users in the late 1980s and through the 1990s.

The H-1 is being evolved from technology established through Japan's N series of rockets, which utilize some hardware and technology from the National Aeronautics and Space Administration's Thor-Delta launcher family.

As development work continues on the first H-1 versions, Japan also is evaluating an upgraded H-1 that could place payloads of 800 kg. (1,760 lb.) to one metric ton in geostationary orbit.

If Japan wants to market the H-1 vehicles for commercial launching services, questions concerning the use of the U.S. technology incorporated in them for commercial ventures would have to be sorted out, a U.S. official said. The official noted, however, that Japan's ability to become a major commercial launch services competitor is limited by several inherent factors. Its launch windows are restricted to two periods per year because of clearances that must be arranged with the Japanese fishing industry in the waters on the country's launcher ranges.

"It is only speculation, but if Japan wants to enter the commercial space market, I think it would be more likely for the country to offer such services as earth-monitoring data from the satellites it develops through its industry and then launches on its own vehicles," the U.S. official said. "This way it could offer marketable services in imaging, plus other earth resources capabilities and satellite transponder capacity, rather than try to work on commercial launcher services separately."

Any competitive threat that may have been posed by the privately funded German Orbital Transport- und Raketen-Aktiengesellschaft (Otrag) seems to have ended for the time being with the company's termination of launch operations in Libya. Otrag had said it would test a two-stage rocket launcher from its Libyan range that could be used to place satellites into geostationary or

Sales Goals Projected for Ariane

Paris—Arianespace, the marketing organization for Europe's Ariane launcher, has set an objective of capturing orders for 25-30% of the approximately 200 satellites expected to be orbited during 1983-90.

Firm contracts already booked for the Ariane have provided for the production of 19 vehicles, and additional commitments are expected.

The 19-launcher total covers the four development vehicles that have been tested during the Ariane's development phase, six additional Arianes for the upcoming European Space Agency promotional series and nine others that are to be launched under Arianespace authority.

According to Arianespace estimates, the organization's order book is worth 2.4 billion francs (approximately $428.5 million), of which 40% originated outside the European Economic Community. In 1984, when Arianespace takes over all Ariane launch activities at the conclusion of the ESA series, the group's annual sales are targeted to be 1.6 billion francs (approximately $285.7 million).

Ariane 4 in French 1982 Budget

Paris—The French government's 1982 budget includes funding for several key elements of the country's near- and long-term space programs. These involve financial support for developing the follow-on Ariane 4 launcher configuration, the construction of a second Spot earth-imaging satellite, establishment of the Spot image marketing support organization and participation in several European Space Agency programs.

Finances for the Ariane 4 will allow development of this latest version to begin this year. Some of the system's contracts are expected to be issued to industry this month. The Ariane 4 will be fitted with a variety of solid or liquid strap-on boosters—or combinations of the two—to produce various launch capabilities up to a heavy-lift version with payload capacity of about 9,460 lb. (AWAST Oct. 12, 1981, p. 87).

The Ariane 4 project is expected to be handled within the framework of ESA, and final ESA approval is under way as the agency's member nations make formal commitments for their shares of program participation.

Other elements of the 1982 French budget provide funding for a second Spot earth-imaging satellite and support for the formation of the Spot image marketing organization.

Provision of the second Spot spacecraft will provide the extension of Spot imaging services for users through the 1980s, according to program officials. The first Spot satellite is under development, and it is targeted for launch on an Ariane 2 launcher in 1984. As with most spacecraft of this type, the Spot spacecraft payload has a design lifetime of two years.

France's 1982 budget provisions also cover the country's participation in several new ESA programs, including the ERS-1 earth resources satellite, a follow-on development program for the ESA Spacelab orbital laboratory facility and a microgravity program.

The ERS-1 is an ocean-monitoring satellite that will carry a synthetic aperture radar, microwave scatterometer and radar altimeter. This satellite is to be based on the same multimission platform bus design used in the French Spot program. Launch for ERS-1 is targeted for 1987.

ESA's Spacelab follow-on development program will provide for continuing development of the orbital facility to be carried in the payload bay of the U. S. space shuttle orbiter (AWAST Dec. 21, 1981, p. 52). The initial work will concentrate on improving the Spacelab design to increase mission duration, and this will be followed by studies of developing free-flying payload units that could be released from the shuttle orbiter for retrieval a minimum of 30 days later. The third follow-on work phase involves studies to prepare Europe for future decisions on its space transportation system, including the possibilities of manned orbital station development with the U. S., or a European development of unmanned platforms based on the Spacelab retrievable carrier.

low-earth orbits. Otrag had offered itself as a private commercial alternative to Ariane and other launchers amid claims by aerospace officials that Otrag was a tax shelter with no real plans to launch satellites (AWAST Dec. 14, 1981, p. 22).

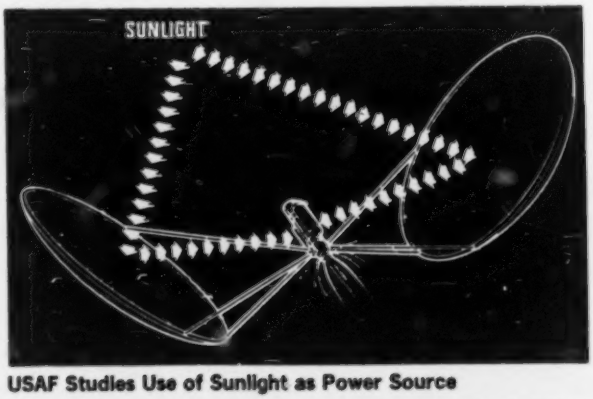
Another private group—this one based in the U. S.—says it is continuing with plans to develop a non-government-sponsored launcher—the Percheron—despite the failure it experienced during ground testing last year (AWAST Aug. 10, 1981, p. 26). Two private companies, Space Services, Inc., of Houston, Tex., and GHC, Inc., of Sunnyvale, Calif., supported development of the Percheron system to compete for commercial payloads with the U. S. Delta and European Ariane.

Brazil plans to develop a satellite and telecommunications network and is seeking bids from worldwide industry sources for such a network that would include the transfer of certain high technology to Brazilian industry. The two competing finalist teams for the Brazilian contract are Canada's Spar with Hughes Aircraft, against a three-way team of France's Aerospatiale, Ford Aerospace and Communications Corp. of the U. S., and Thomson CSF of France. As part of the Aerospatiale/Ford/Thomson CSF bid, France has authorized a package offer for Brazil that would include financial support for the satellites, plus Arianespace-backed launches on a double-payload configuration of the Ariane, and the supply of ground communications stations.

The launcher capabilities that exist in the Soviet Union and that are developing in China are considered to be competitive only on a political level, since the two countries' policies keep much of their programs secret. The Soviet Union, for example, has launched some satellites for India and participated with France in cooperative spacecraft projects that included launches on Soviet vehicles, but this is significantly different from commercialized handling of launcher capacity.

China is in the early development of its launchers. Chinese officials visiting western Europe in 1981 indicated the country may be interested in expanding its contacts with other nations' aerospace industries and in the future could discuss the launch of payloads for certain countries. According to European aerospace experts, the Chinese Long March 3 launcher vehicle is similar in concept to the Ariane.

The primary competitor for Europe's Ariane is the U. S. Delta launcher, which



USAF Studies Use of Sunlight as Power Source

Use of sunlight as the power source for an advanced space propulsion system is the goal of the solar rocket propulsion program at the USAF Rocket Propulsion Laboratory at Edwards AFB, Calif. The concept features lightweight mirrors to focus solar energy into the rocket chamber where propellant is heated to temperatures approximately 2,300K, then exhausted through a conventional rocket nozzle. Missions envisioned for the solar rocket would be those requiring long duration, low thrust (1 lb. or less) applications.

has one of the largest booking levels in the program's 21-year history. The initial version was flown in 1960, and future growth configurations have been studied by its manufacturer, McDonnell Douglas Astronautics Corp., for Delta vehicles that could boost transfer orbit throw-weight capability up to 3,000 lb.

Program officials said Delta has had an overall reliability of about 93% in total firings since 1960. Substantial reliability improvements that were implemented after a Delta launch failure in 1974 have added to the launcher's success rate, with about a 96% reliability rate attained during the launches made during the past seven years.

"The Delta has a reliability record that will be difficult to equal by other expendable launchers," a U.S. program official said.

"As far as the marketing aspects are concerned, the program sees a continuing need among the payload community, and the U.S. has continued to support the Delta users even though our marketing may not have the same commercialized structure as the more recent European approach with Arianespace."

One potential area of new U.S. launcher competition that will be monitored closely by European Ariane participants is the possible development of new U.S. expendable vehicles and shuttle-derived cargo vehicles. A study is under way by Boeing for a new unmanned vehicle based on the recoverable space shuttle solid rocket booster (AWAST Dec. 7, 1981, p. 22). This effort is among several U.S. industry examinations of systems that could be used for a "mixed fleet" launcher concept. □

Ariane Contractors

Evry, France—Arianespace is working with seven contractors in the manufacture of Ariane launchers. These are:

- **France's Aerospatiale**—Responsibility for the first and third stages and the launch vehicle's overall design.
- **Societe Europeenne de Propulsion of France**—This company has the contract for propulsion systems for the vehicle's three stages.
- **Germany's ERNO**—Development and production of the second stage.
- **Matra of France**—Responsible for Ariane's equipment bay.
- **Contraves of Switzerland**—Production of the payload fairing.
- **France's Air Liquide**—Produces the third-stage tank.
- **Italy's Difesa e Spazio**—Responsible for the additional solid boosters that will be used in the growth versions of Ariane.

These companies subcontract a sizable portion of their production work to various firms in the 11 countries participating in the Ariane program.

IV. MILITARIZATION OF SPACE

National Security

Address to the Nation. March 23, 1983

My fellow Americans, thank you for sharing your time with me tonight.

The subject I want to discuss with you, peace and national security, is both timely and important. Timely, because I've reached a decision which offers a new hope for our children in the 21st century, a decision I'll tell you about in a few minutes. And important because there's a very big decision that you must make for yourselves. This subject involves the most basic duty that any President and any people share, the duty to protect and strengthen the peace.

At the beginning of this year, I submitted to the Congress a defense budget which reflects my best judgment of the best understanding of the experts and specialists who advise me about what we and our allies must do to protect our people in the years ahead. That budget is much more than a long list of numbers, for behind all the numbers lies America's ability to prevent the greatest of human tragedies and preserve our free way of life in a sometimes dangerous world. It is part of a careful, long-term plan to make America strong again after too many years of neglect and mistakes.

Our efforts to rebuild America's defenses and strengthen the peace began 2 years ago when we requested a major increase in the defense program. Since then, the amount of those increases we first proposed has been reduced by half, through improvements in management and procurement and other savings.

The budget request that is now before the Congress has been trimmed to the limits of safety. Further deep cuts cannot be made without seriously endangering the security of the Nation. The choice is up to the men and women you've elected to the Congress, and that means the choice is up to you.

Tonight, I want to explain to you what this defense debate is all about and why I'm convinced that the budget now before the Congress is necessary, responsible, and de-

Reproduced from Reagan, Ronald. National security address to the Nation, March 23, 1983. Weekly compilation of Presidential documents, v. 19, Mar. 28, 1983: 442-448.

serving of your support. And I want to offer hope for the future.

But first, let me say what the defense debate is not about. It is not about spending arithmetic. I know that in the last few weeks you've been bombarded with numbers and percentages. Some say we need only a 5-percent increase in defense spending. The so-called alternate budget backed by liberals in the House of Representatives would lower the figure to 2 to 3 percent, cutting our defense spending by $163 billion over the next 5 years. The trouble with all these numbers is that they tell us little about the kind of defense program America needs or the benefits and security and freedom that our defense effort buys for us.

What seems to have been lost in all this debate is the simple truth of how a defense budget is arrived at. It isn't done by deciding to spend a certain number of dollars. Those loud voices that are occasionally heard charging that the Government is trying to solve a security problem by throwing money at it are nothing more than noise based on ignorance. We start by considering what must be done to maintain peace and review all the possible threats against our security. Then a strategy for strengthening peace and defending against those threats must be agreed upon. And, finally, our defense establishment must be evaluated to see what is necessary to protect against any or all of the potential threats. The cost of achieving these ends is totaled up, and the result is the budget for national defense.

There is no logical way that you can say, let's spend x billion dollars less. You can only say, which part of our defense measures do we believe we can do without and still have security against all contingencies? Anyone in the Congress who advocates a percentage or a specific dollar cut in defense spending should be made to say what part of our defenses he would eliminate, and he should be candid enough to acknowledge that his cuts mean cutting our commitments to allies or inviting greater risk or both.

The defense policy of the United States is based on a simple premise: The United States does not start fights. We will never be an aggressor. We maintain our strength in order to deter and defend against aggression—to preserve freedom and peace.

Since the dawn of the atomic age, we've sought to reduce the risk of war by maintaining a strong deterrent and by seeking genuine arms control. "Deterrence" means simply this: making sure any adversary who thinks about attacking the United States, or our allies, or our vital interests, concludes that the risks to him outweigh any potential gains. Once he understands that, he won't attack. We maintain the peace through our strength, weakness only invites aggression.

This strategy of deterrence has not changed. It still works. But what it takes to maintain deterrence has changed. It took one kind of military force to deter an attack when we had far more nuclear weapons than any other power; it takes another kind now that the Soviets, for example, have enough accurate and powerful nuclear weapons to destroy virtually all of our missiles on the ground. Now, this is not to say that the Soviet Union is planning to make war on us. Nor do I believe a war is inevitable—quite the contrary. But what must be recognized is that our security is based on being prepared to meet all threats.

There was a time when we depended on coastal forts and artillery batteries, because, with the weaponry of that day, any attack would have had to come by sea. Well, this is a different world, and our defenses must be based on recognition and awareness of the weaponry possessed by other nations in the nuclear age.

We can't afford to believe that we will never be threatened. There have been two world wars in my lifetime. We didn't start them and, indeed, did everything we could to avoid being drawn into them. But we were ill-prepared for both. Had we been better prepared, peace might have been preserved.

For 20 years the Soviet Union has been accumulating enormous military might. They didn't stop when their forces exceeded all requirements of a legitimate defensive capability. And they haven't stopped now. During the past decade and a half, the Soviets have built up a massive arsenal of new strategic nuclear weapons—weapons that can strike directly at the United States.

As an example, the United States introduced its last new intercontinental ballistic missile, the Minute Man III, in 1969, and we're now dismantling our even older Titan missiles. But what has the Soviet Union done in these intervening years? Well, since 1969 the Soviet Union has built five new classes of ICBM's, and upgraded these eight times. As a result, their missiles are much more powerful and accurate than they were several years ago, and they continue to develop more, while ours are increasingly obsolete.

The same thing has happened in other areas. Over the same period, the Soviet Union built 4 new classes of submarine-launched ballistic missiles and over 60 new missile submarines. We built 2 new types of submarine missiles and actually withdrew 10 submarines from strategic missions. The Soviet Union built over 200 new Backfire bombers, and their brand new Blackjack bomber is now under development. We haven't built a new long-range bomber since our B–52's were deployed about a quarter of a century ago, and we've already retired several hundred of those because of old age. Indeed, despite what many people think, our strategic forces only cost about 15 percent of the defense budget.

Another example of what's happened: In 1978 the Soviets had 600 intermediate-range nuclear missiles based on land and were beginning to add the SS–20—a new, highly accurate, mobile missile with 3 warheads. We had none. Since then the Soviets have strengthened their lead. By the end of 1979, when Soviet leader Brezhnev declared "a balance now exists," the Soviets had over 800 warheads. We still had none. A year ago this month, Mr. Brezhnev pledged a moratorium, or freeze, on SS–20 deployment. But by last August, their 800 warheads had become more than 1,200. We still had none. Some freeze. At this time Soviet Defense Minister Ustinov announced "approximate parity of forces continues to exist." But the Soviets are still adding an average of 3 new warheads a week, and now have 1,300. These warheads can reach their targets in a matter of a few minutes. We still have none. So far, it seems that the Soviet definition of parity is a box score of 1,300 to nothing, in their favor.

So, together with our NATO allies, we decided in 1979 to deploy new weapons, beginning this year, as a deterrent to their SS–20's and as an incentive to the Soviet Union to meet us in serious arms control negotiations. We will begin that deployment late this year. At the same time, however, we're willing to cancel our program if the Soviets will dismantle theirs. This is what we've called a zero-zero plan. The Soviets are now at the negotiating table—and I think it's fair to say that without our planned deployments, they wouldn't be there.

Now, let's consider conventional forces. Since 1974 the United States has produced 3,050 tactical combat aircraft. By contrast, the Soviet Union has produced twice as many. When we look at attack submarines, the United States has produced 27 while the Soviet Union has produced 61. For armored vehicles, including tanks, we have produced 11,200. The Soviet Union has produced 54,000—nearly 5 to 1 in their favor. Finally, with artillery, we've produced 950 artillery and rocket launchers while the Soviets have produced more than 13,000—a staggering 14-to-1 ratio.

There was a time when we were able to offset superior Soviet numbers with higher quality, but today they are building weapons as sophisticated and modern as our own.

As the Soviets have increased their military power, they've been emboldened to extend that power. They're spreading their military influence in ways that can directly challenge our vital interests and those of our allies.

The following aerial photographs, most of them secret until now, illustrate this point in a crucial area very close to home: Central America and the Caribbean Basin. They're not dramatic photographs. But I think they help give you a better understanding of what I'm talking about.

This Soviet intelligence collection facility, less than a hundred miles from our coast, is the largest of its kind in the world. The acres and acres of antennae fields and intelligence monitors are targeted on key U.S. military installations and sensitive activities. The installation in Lourdes, Cuba, is manned by 1,500 Soviet technicians. And

the satellite ground station allows instant communications with Moscow. This 28-square-mile facility has grown by more than 60 percent in size and capability during the past decade.

In western Cuba, we see this military airfield and it complement of modern, Soviet-built Mig-23 aircraft. The Soviet Union uses this Cuban airfield for its own long-range reconnaissance missions. And earlier this month, two modern Soviet antisubmarine warfare aircraft began operating from it. During the past 2 years, the level of Soviet arms exports to Cuba can only be compared to the levels reached during the Cuban missile crisis 20 years ago.

This third photo, which is the only one in this series that has been previously made public, shows Soviet military hardware that has made its way to Central America. This airfield with its MI–8 helicopters, anti-aircraft guns, and protected fighter sites is one of a number of military facilities in Nicaragua which has received Soviet equipment funneled through Cuba, and reflects the massive military buildup going on in that country.

On the small island of Grenada, at the southern end of the Caribbean chain, the Cubans, with Soviet financing and backing, are in the process of building an airfield with a 10,000-foot runway. Grenada doesn't even have an air force. Who is it intended for? The Caribbean is a very important passageway for our international commerce and military lines of communication. More than half of all American oil imports now pass through the Caribbean. The rapid buildup of Grenada's military potential is unrelated to any conceivable threat to this island country of under 110,000 people and totally at odds with the pattern of other eastern Caribbean States, most of which are unarmed.

The Soviet-Cuban militarization of Grenada, in short, can only be seen as power projection into the region. And it is in this important economic and strategic area that we're trying to help the Governments of El Salvador, Costa Rica, Honduras, and others in their struggles for democracy against guerrillas supported through Cuba and Nicaragua.

These pictures only tell a small part of the story. I wish I could show you more without compromising our most sensitive intelligence sources and methods. But the Soviet Union is also supporting Cuban military forces in Angola and Ethiopia. They have bases in Ethiopia and South Yemen, near the Persian Gulf oil fields. They've taken over the port that we built at Cam Ranh Bay in Vietnam. And now for the first time in history, the Soviet Navy is a force to be reckoned with in the South Pacific.

Some people may still ask: Would the Soviets ever use their formidable military power? Well, again, can we afford to believe they won't? There is Afghanistan. And in Poland, the Soviets denied the will of the people and in so doing demonstrated to the world how their military power could also be used to intimidate.

The final fact is that the Soviet Union is acquiring what can only be considered an offensive military force. They have continued to build far more intercontinental ballistic missiles than they could possibly need simply to deter an attack. Their conventional forces are trained and equipped not so much to defend against an attack as they are to permit sudden, surprise offensives of their own.

Our NATO allies have assumed a great defense burden, including the military draft in most countries. We're working with them and our other friends around the world to do more. Our defensive strategy means we need military forces that can move very quickly, forces that are trained and ready to respond to any emergency.

Every item in our defense program—our ships, our tanks, our planes, our funds for training and spare parts—is intended for one all-important purpose: to keep the peace. Unfortunately, a decade of neglecting our military forces had called into question our ability to do that.

When I took office in January 1981, I was appalled by what I found: American planes that couldn't fly and American ships that couldn't sail for lack of spare parts and trained personnel and insufficient fuel and ammunition for essential training. The inevitable result of all this was poor morale in our Armed Forces, difficulty in recruiting the brightest young Americans to wear the uniform, and difficulty in convincing our

most experienced military personnel to stay on.

There was a real question then about how well we could meet a crisis. And it was obvious that we had to begin a major modernization program to ensure we could deter aggression and preserve the peace in the years ahead.

We had to move immediately to improve the basic readiness and staying power of our conventional forces, so they could meet—and therefore help deter—a crisis. We had to make up for lost years of investment by moving forward with a long-term plan to prepare our forces to counter the military capabilities our adversaries were developing for the future.

I know that all of you want peace, and so do I. I know too that many of you seriously believe that a nuclear freeze would further the cause of peace. But a freeze now would make us less, not more, secure and would raise, not reduce, the risks of war. It would be largely unverifiable and would seriously undercut our negotiations on arms reduction. It would reward the Soviets for their massive military buildup while preventing us from modernizing our aging and increasingly vulnerable forces. With their present margin of superiority, why should they agree to arms reductions knowing that we were prohibited from catching up?

Believe me, it wasn't pleasant for someone who had come to Washington determined to reduce government spending, but we had to move forward with the task of repairing our defenses or we would lose our ability to deter conflict now and in the future. We had to demonstrate to any adversary that aggression could not succeed, and that the only real solution was substantial, equitable, and effectively verifiable arms reduction—the kind we're working for right now in Geneva.

Thanks to your strong support, and bipartisan support from the Congress, we began to turn things around. Already, we're seeing some very encouraging results. Quality recruitment and retention are up dramatically—more high school graduates are choosing military careers, and more experienced career personnel are choosing to stay. Our men and women in uniform at last are getting the tools and training they need to do their jobs.

Ask around today, especially among our young people, and I think you will find a whole new attitude toward serving their country. This reflects more than just better pay, equipment, and leadership. You the American people have sent a signal to these young people that it is once again an honor to wear the uniform. That's not something you measure in a budget, but it's a very real part of our nation's strength.

It'll take us longer to build the kind of equipment we need to keep peace in the future, but we've made a good start.

We haven't built a new long-range bomber for 21 years. Now we're building the B–1. We hadn't launched one new strategic submarine for 17 years. Now we're building one Trident submarine a year. Our land-based missiles are increasingly threatened by the many huge, new Soviet ICBM's. We're determining how to solve that problem. At the same time, we're working in the START and INF negotiations with the goal of achieving deep reductions in the strategic and intermediate nuclear arsenals of both sides.

We have also begun the long-needed modernization of our conventional forces. The Army is getting its first new tank in 20 years. The Air Force is modernizing. We're rebuilding our Navy, which shrank from about a thousand ships in the late 1960's to 453 during the 1970's. Our nation needs a superior navy to support our military forces and vital interests overseas. We're now on the road to achieving a 600-ship navy and increasing the amphibious capabilities of our marines, who are now serving the cause of peace in Lebanon. And we're building a real capability to assist our friends in the vitally important Indian Ocean and Persian Gulf region.

This adds up to a major effort, and it isn't cheap. It comes at a time when there are many other pressures on our budget and when the American people have already had to make major sacrifices during the recession. But we must not be misled by those who would make defense once again the scapegoat of the Federal budget.

The fact is that in the past few decades we have seen a dramatic shift in how we spend the taxpayer's dollar. Back in 1955, payments to individuals took up only about

38-036 O - 84 - 70

20 percent of the Federal budget. For nearly three decades, these payments steadily increased and, this year, will account for 49 percent of the budget. By contrast, in 1955 defense took up more than half of the Federal budget. By 1980 this spending had fallen to a low of 23 percent. Even with the increase that I am requesting this year, defense will still amount to only 28 percent of the budget.

The calls for cutting back the defense budget come in nice, simple arithmetic. They're the same kind of talk that led the democracies to neglect their defenses in the 1930's and invited the tragedy of World War II. We must not let that grim chapter of history repeat itself through apathy or neglect.

This is why I'm speaking to you tonight—to urge you to tell your Senators and Congressmen that you know we must continue to restore our military strength. If we stop in midstream, we will send a signal of decline, of lessened will, to friends and adversaries alike. Free people must voluntarily, through open debate and democratic means, meet the challenge that totalitarians pose by compulsion. It's up to us, in our time, to choose and choose wisely between the hard but necessary task of preserving peace and freedom and the temptation to ignore our duty and blindly hope for the best while the enemies of freedom grow stronger day by day.

The solution is well within our grasp. But to reach it, there is simply no alternative but to continue this year, in this budget, to provide the resources we need to preserve the peace and guarantee our freedom.

Now, thus far tonight I've shared with you my thoughts on the problems of national security we must face together. My predecessors in the Oval Office have appeared before you on other occasions to describe the threat posed by Soviet power and have proposed steps to address that threat. But since the advent of nuclear weapons, those steps have been increasingly directed toward deterrence of aggression through the promise of retaliation.

This approach to stability through offensive threat has worked. We and our allies have succeeded in preventing nuclear war for more than three decades. In recent months, however, my advisers, including in particular the Joint Chiefs of Staff, have underscored the necessity to break out of a future that relies solely on offensive retaliation for our security.

Over the course of these discussions, I've become more and more deeply convinced that the human spirit must be capable of rising above dealing with other nations and human beings by threatening their existence. Feeling this way, I believe we must thoroughly examine every opportunity for reducing tensions and for introducing greater stability into the strategic calculus on both sides.

One of the most important contributions we can make is, of course, to lower the level of all arms, and particularly nuclear arms. We're engaged right now in several negotiations with the Soviet Union to bring about a mutual reduction of weapons. I will report to you a week from tomorrow my thoughts on that score. But let me just say, I'm totally committed to this course.

If the Soviet Union will join with us in our effort to achieve major arms reduction, we will have succeeded in stabilizing the nuclear balance. Nevertheless, it will still be necessary to rely on the specter of retaliation, on mutual threat. And that's a sad commentary on the human condition. Wouldn't it be better to save lives than to avenge them? Are we not capable of demonstrating our peaceful intentions by applying all our abilities and our ingenuity to achieving a truly lasting stability? I think we are. Indeed, we must.

After careful consultation with my advisers, including the Joint Chiefs of Staff, I believe there is a way. Let me share with you a vision of the future which offers hope. It is that we embark on a program to counter the awesome Soviet missile threat with measures that are defensive. Let us turn to the very strengths in technology that spawned our great industrial base and that have given us the quality of life we enjoy today.

What if free people could live secure in the knowledge that their security did not rest upon the threat of instant U.S. retaliation to deter a Soviet attack, that we could intercept and destroy strategic ballistic missiles before they reached our own soil or that of our allies?

I know this is a formidable, technical task, one that may not be accomplished before the end of this century. Yet, current technology has attained a level of sophistication where it's reasonable for us to begin this effort. It will take years, probably decades of effort on many fronts. There will be failures and setbacks, just as there will be successes and breakthroughs. And as we proceed, we must remain constant in preserving the nuclear deterrent and maintaining a solid capability for flexible response. But isn't it worth every investment necessary to free the world from the threat of nuclear war? We know it is.

In the meantime, we will continue to pursue real reductions in nuclear arms, negotiating from a position of strength that can be ensured only by modernizing our strategic forces. At the same time, we must take steps to reduce the risk of a conventional military conflict escalating to nuclear war by improving our non-nuclear capabilities.

America does possess—now—the technologies to attain very significant improvements in the effectiveness of our conventional, non-nuclear forces. Proceeding boldly with these new technologies, we can significantly reduce any incentive that the Soviet Union may have to threaten attack against the United States or its allies.

As we pursue our goal of defensive technologies, we recognize that our allies rely upon our strategic offensive power to deter attacks against them. Their vital interests and ours are inextricably linked. Their safety and ours are one. And no change in technology can or will alter that reality. We must and shall continue to honor our commitments.

I clearly recognize that defensive systems have limitations and raise certain problems and ambiguities. If paired with offensive systems, they can be viewed as fostering an aggressive policy, and no one wants that. But with these considerations firmly in mind, I call upon the scientific community in our country, those who gave us nuclear weapons, to turn their great talents now to the cause of mankind and world peace, to give us the means of rendering these nuclear weapons impotent and obsolete.

Tonight, consistent with our obligations of the ABM treaty and recognizing the need for closer consultation with our allies, I'm taking an important first step. I am directing a comprehensive and intensive effort to define a long-term research and development program to begin to achieve our ultimate goal of eliminating the threat posed by strategic nuclear missiles. This could pave the way for arms control measures to eliminate the weapons themselves. We seek neither military superiority nor political advantage. Our only purpose—one all people share—is to search for ways to reduce the danger of nuclear war.

My fellow Americans, tonight we're launching an effort which holds the promise of changing the course of human history. There will be risks, and results take time. But I believe we can do it. As we cross this threshold, I ask for your prayers and your support.

Thank you, good night, and God bless you.

Note: The President spoke at 8:02 p.m. from the Oval Office at the White House. The address was broadcast live on nationwide radio and television.

Following his remarks, the President met in the White House with a number of administration officials, including members of the Cabinet, the White House staff, and the Joint Chiefs of Staff, and former officials of past administrations to discuss the address.

U.S. POLICY ON ASAT ARMS CONTROL

COMMUNICATION

FROM

THE PRESIDENT OF THE UNITED STATES

TRANSMITTING

A REPORT ON HIS ADMINISTRATION'S POLICY ON ARMS CONTROL FOR ANTISATELLITE SYSTEMS AS REQUIRED IN THE CONFERENCE REPORT FOR THE DEPARTMENT OF DEFENSE APPROPRIATIONS ACT FOR FISCAL YEAR 1984

APRIL 3, 1984.—Referred to the Committee on Appropriations and ordered to be printed

---

U.S. GOVERNMENT PRINTING OFFICE

31-011 O WASHINGTON : 1984

THE WHITE HOUSE,
Washington, March 31, 1984.

Hon. THOMAS P. O'NEILL, JR.,
Speaker of the House of Representatives,
Washington, D.C.

DEAR MR. SPEAKER: I am pleased to transmit this report on my Administration's policy on arms control for antisatellite systems as required in the Conference Report for the Department of Defense Appropriations Act for Fiscal Year 1984.

The United States is committed to the exploration and use of space by all nations for peaceful purposes and for the benefit of mankind. Among the activities conducted by the United States in space is the pursuit of fundamental national security objectives. Arms control arrangements for space would serve these objectives if they contributed to our overall deterrence posture and reduce the risk of conflict.

With this in mind, I announced on July 4, 1982, the basic posture of this Administration which I now reaffirm:

"The United States will continue to study space arms control options. The United States will consider verifiable and equitable arms control measures that would ban or otherwise limit testing and deployment of specific weapons systems, should those measures be compatible with United States national security."

Guided by these criteria, the United States has been studying a range of possible options for space arms control, with a view to possible negotiations with the Soviet Union and other nations, if such negotiations would serve U.S. interests. Within the U.S. Government, this work is being conducted by an Interdepartmental Group chaired by the Office of the Secretary of Defense and the Arms Control and Disarmament Agency. The United States is also prepared to examine space arms control issues in the Conference on Disarmament (CD). However, no arrangements or agreements beyond those already governing military activities in outer space have been found to date that are judged to be in the overall interest of the United States and its Allies. The factors that impede the identification of effective ASAT arms control measures include significant difficulties of verification, diverse sources of threats to U.S. and Allied satellites, and threats posed by Soviet targeting and reconnaissance satellites that undermine conventional and nuclear deterrence.

Notwithstanding these difficulties, the United States is continuing to study space arms control, in search of selected limits on specific types of space systems or activities in space that could satisfactorily deal with problems, such as those described above. Until we have determined whether there are, in fact, practical solutions to these problems, I do not believe it would be productive to engage in formal international negotiations. The United States remains ready, however, to examine the problems and potential of space arms control at the Conference on Disarmament in Geneva.

The attached Report on U.S. Policy on Antisatellite Arms Control sets forth in greater detail the views of my Administration on this important issue. It is unclassified and is suitable for general release. As you are aware, information regarding certain U.S. and Soviet space activities involves sensitive information. Accordingly, I am also transmitting a classified Report providing such information under separate cover. In preparing both Reports, every effort was made to respond to the questions asked by various Committees and Members of Congress.

Sincerely,

RONALD REAGAN.

REPORT TO CONGRESS

U.S. POLICY ON ASAT ARMS CONTROL

Preface

The Congressional conference report for the Department of Defense Appropriations Act for the Fiscal Year ending September 30, 1984 states:

> The conferees agree to provide $19,409,000 for advance procurement for the Antisatellite (ASAT) program as proposed by the Senate, instead of no funds as proposed by the House. However, the conferees direct that these funds not be obligated or expended until 45 days following submission to the Congress of a comprehensive report on U.S. policy on arms control plans and objectives in the field of ASAT systems. In no event shall such report be submitted later than March 31, 1984. Such report should include specific steps the Administration contemplates undertaking, within the context of U.S. - Soviet negotiations, to seek a verifiable agreement with the Soviet Union to ban or strictly limit existing and future ASAT systems. The report should be unclassified, with classified addenda as required, and suitable for general release.

This Report to Congress fulfills that requirement. It summarizes U.S. national security requirements pertaining to ASAT weaponry, and the problems and possibilities for ASAT arms control. The Report is in two versions, one is unclassified and the other, containing additional detail, is classified.

U.S. POLICY ON ASAT ARMS CONTROL

I. Overview

U.S. arms control policy must serve our fundamental national security objectives. In particular, arms control arrangements should reduce the risk of war (through measures which strengthen deterrence, increase confidence, and enhance strategic stability) or reduce the destructiveness of warfare. Arms control arrangements for space are desirable if they contribute to our overall deterrence posture and reduce the risk of conflict, not as ends in themselves. Similarly, possible limits or bans on anti-satellite (ASAT) arms must be judged not only in their ability to limit damage to space objects, but also in their contribution to achieving the basic objectives of arms control with respect to terrestrial conventional and nuclear conflict.

The U.S. National Space Policy, announced by the President July 4, 1982, is consistent with the long-standing U.S. approach to space arms control in previous agreements. It states:

> "The United States will continue to study space arms control options. The United States will consider verifiable and equitable arms control measures that would ban or otherwise limit testing and deployment of specific weapons systems, should those measures be compatible with United States national security."

Guided by these criteria, the United States has been studying a range of possible options for space arms control with a view to possible negotiations with the Soviet Union and other nations, if such negotiations would serve U.S. interests. The United States is also prepared to examine space arms control issues in the Conference on Disarmament (CD). However, no arrangements or agreements beyond those already governing military activities in outer space have been found to date that are judged to be in the overall interest of the United States and its Allies. The factors which impede the identification of effective ASAT arms control measures include significant difficulties of verification, diverse sources of threats to U.S. and Allied satellites and threats posed by Soviet targeting and reconnaissance satellites which undermine conventional and nuclear deterrence.

Notwithstanding these difficulties, the United States is continuing to study space arms control, in search of selected limits on specific types of space systems or activities in space which could satisfactorily deal with problems such as those described above. Until we have determined whether there are, in fact, practical solutions to these problems, we do not believe it would be productive to engage in formal international negotiations. The United States remains ready, however, to examine

the problems and potential of space arms control at the Conference on Disarmament.

II. ASAT Arms Control Considerations

U.S. policy toward limiting arms in space is part of the overall U.S. commitment to effective arms control. This commitment is reflected, for example, in our proposals in START, INF and MBFR for achieving substantial, verifiable reductions in nuclear and conventional forces, and in U.S. proposals for a chemical weapons ban. This commitment also is basic to the U.S. approach to space arms control. The United States is party to, and had a lead role in negotiating, a number of major international agreements that apply to space, including the Outer Space, Anti-Ballistic Missile (ABM) and Limited Test Ban Treaties. In addition, the United Nations Charter is expressly made applicable to space activities by the Outer Space Treaty.

These agreements provide a substantial, existing body of law regarding space arms control. Included in existing law is a ban on testing, orbiting, or stationing of nuclear weapons or other weapons of mass destruction in space; a ban on placing military installations on celestial bodies; a ban on development, testing and deployment of space-based ABM systems or their components; and a requirement for appropriate international consultations before conducting any activity or experiment that would cause potentially harmful interference with other countries' peaceful space activities.

United States arms control policy and plans for ASAT systems, as well as for any space weapons generally, result from an examination of a broad spectrum of factors. These factors relate to military activities in space and other activities regarding conventional and nuclear weapons, U.S. foreign policy activities and even U.S. commercial and scientific uses of space. In fact, ASAT arms control appears to span a greater breadth of subjects than any other area of arms control.

Previous ASAT Talks

At the initiative of the United States, bilateral negotiations between the US and USSR on control of anti-satellite weapons were held in 1978-79. These talks involved an extensive discussion of some of the problems of space arms control, and revealed major differences between the two sides. Further U.S. study since then has brought the whole topic of space arms control into sharper focus.

Potential Benefits of Space Arms Control

The potential benefits of any ASAT control regime would depend on both its framework and its details. The spectrum of possible space arms control measures includes bans on specialized

ASAT weapons and much less ambitious undertakings. To be acceptable any measure must be equitable, effectively verifiable and compatible with our national security. If any space arms control measures met these criteria, and were complied with, then they would have a number of potential benefits. For example, depending on the scope and effectiveness of an agreement, it might:

1. Limit specialized threats to satellites and constrain future threats to such key satellites as those for early warning. Such limitations on specialized threats to satellites, together with satellite survivability measures, could help preserve and enhance stability.

2. Raise the political threshold for attacks against satellites. Restricting threatening activity and/or prohibiting attacks on satellites would add to existing international law aimed at lowering the likelihood of conflict in space.

3. Meet some international concerns regarding the use of space for military purposes.

Problems Facing ASAT Arms Control

In addition to the potential benefits of space arms control, a balanced study of this topic must take into account a number of problems. These include: the need for effective verification; the potential for breakout; the risks of disclosing sensitive information; the problems of definition of space weapons; the vulnerability of satellite support systems; and Soviet military space activity.

Verification. Effective verification is fundamental to arms control. This applies to space arms control as it does to arms reductions in other fora. The Congressional language mandating ASAT arms control efforts has been uniformly specific on the matter of verification: any ban on ASAT systems is to be verifiable.

In general, verification of arms control agreements suffers from the extremely asymmetric degree of openness between the United States and the Soviet Union. The open U.S. society makes the Soviet task of monitoring U.S. activities regarding arms control compliance a relatively easy matter. In contrast, the closed Soviet society and the general Soviet tendency toward secrecy make U.S. monitoring and verification of compliance much more difficult. This problem is aggravated for ASAT systems because the satellites which serve U.S. and Allied security are few in number. Cheating on anti-satellite limitations, even on a small scale, could pose a disproportionate risk to the United States.

In this regard, the Soviets would have a far easier problem of verifying compliance with limitations on the U.S. ASAT

system than we would have on the Soviet system. For example, a ban on all ASAT systems would require that the Soviet ASAT interceptor system be eliminated. The Soviet interceptor is relatively small and is launched by a type of space booster that the Soviets use for other space launch missions. It is not clear how many interceptors or boosters have been manufactured. The USSR could maintain a covert supply of interceptors which could be readied quickly for operational use, probably without risk of U.S. detection. Launch vehicles could be diverted from other missions to launch ASAT interceptors.

Verification problems apply to other aspects of space arms control as well. For instance, tests of a ground-based laser ASAT weapon could be concealed. In addition, determining with confidence whether an object hundreds of kilometers above the earth has been damaged could, in practice, be extremely difficult, and from what source it had been damaged could be extremely difficult or impossible. It may be difficult to determine whether a satellite has been damaged by electronic countermeasures. It is also difficult, or in some cases could be impossible, to determine whether an orbiting satellite contains a weapon.

Additional verification problems arise if ASAT testing is banned or limited. The wide variety of ASAT systems listed below in the discussion of problems of definition, and the fact that ASAT capabilities can be a by-product of systems developed for other missions, create problems of identifying what would be prohibited under testing limitations. The fact that ASAT capabilities are inherent in some systems developed for other missions or are amenable to undetected or surreptitious development makes it impossible to verify compliance with a truly comprehensive testing limitation that would eliminate tests of all methods of countering satellites. Test bans for a more limited class of ASAT systems may be verifiable, and these are being studied to determine if they are in our national interest. The breakout potential of that limited class of ASAT systems is very troublesome and creates doubt that limited test bans could be effective.

The difficult verification problems could, in some cases, be mitigated by future technological developments, or by cooperative measures contained in future arms control agreements. Such possibilities are under study.

Breakout. Among the criteria which must be used in evaluating the implications for national security of any potential arms control measure is that of "breakout." This is the risk that a nation could gain a unilateral advantage if the agreement ceased to remain in force for any reason, for example through sudden abrogation, and obtain a head start in building or deploying a type of weapon which has been banned or severely limited. The importance of certain critical U.S. satellites, which are limited in numbers, could create an incentive for the Soviets to maintain a breakout capability.

Breakout potential could exist even if the Soviets, upon agreeing to a ban on ASAT systems, were to destroy all of their existing systems. The Soviets could retain the capability to redeploy quickly a system in which they would have confidence. If prior to the ban the United States had not tested its MV ASAT system, the Soviets alone would possess such proven technology. It might take the Soviets a year or less to deploy their system again.

Under a strict ASAT arms control regime, it is conceivable that the Soviets could change the basic character of their ASAT program. The USSR could have additional ASAT capability in equipment amenable to undetected or surreptitious development, which could be brought to operational status, or to a status that would permit rapid breakout. For example, any nation routinely conducting space rendezvous and docking operations, as the USSR does, could, under the guise of that activity, develop spacecraft equipped to maneuver into the path of, or detonate next to, another nation's spacecraft. Other types of systems amenable to such development include ballistic missiles with modified guidance software such as ICBMs, SLBMs and MRBMs, as well as space boosters with nuclear payloads. There is little reason to believe that the USSR would use any of these non-optimum capabilities in lieu of the systems with known ASAT capabilities. However, a ban on the more readily identifiable ASAT systems could increase the likelihood that other systems would be covertly developed to have ASAT capability.

Disclosure of Information. While the difficult verification problems associated with ASAT arms control might be decreased with the establishment of cooperative measures, in some instances these measures could cause other problems. Information regarding certain U.S. space systems that are associated with national security is among the most sensitive information within the government. Cooperative measures with the objective of enhancing verification of an ASAT arms control agreement might require access to U.S. space systems that were alleged by the Soviets to have ASAT capabilities, and hence could create an unacceptable risk of compromising the protection of that information. Such measures could also have adverse effects on civil uses of space.

Definition. It is difficult to define what constitutes a space weapon for arms control purposes. There are technologies and systems designed for purposes other than ASAT, even some with little or no ASAT capabilities, which may be difficult to exclude from an ASAT definition. Likewise, there are technologies and systems which could have an ASAT application that might not be included in an ASAT definition.

The U.S. Congress has shown concern over space system survivability problems, especially in legislation which each chamber has passed relating the U.S. ASAT program to arms control. The Senate passed a measure to establish criteria

governing the testing of ASAT warheads; in the deliberations over that provision, it was argued that "unless (ASAT) development is stopped, our most important and sensitive military satellites will be in jeopardy." The House of Representatives passed a measure deleting advanced procurement funds for the U.S. ASAT program; in those deliberations, it was argued "that the survival of current and projected U.S. space systems is vital to the national security of the United States." In keeping with those broadly-based satellite survivablity concerns we need to recognize that "ASAT capability" relates to all systems capable of damaging, destroying or otherwise interrupting the functioning of satellites. Such systems include:

-- maneuvering spacecraft (equipped to maneuver into the path of, or to detonate next to, another nation's spacecraft) such as the coorbital interceptor operationally deployed by the USSR.

-- Direct ascent interceptors such as exo-atmospheric ABM missiles, ballistic missiles with modified guidance logic, space boosters carrying nuclear payloads, and homing vehicles such as the miniature vehicle system undergoing development by the United States.

-- Directed energy weapons such as lasers and particle beams, (either ground-based or space-based, having sufficient power to damage satellites or their sensors).

-- Electronic countermeasures of sufficient power output to damage or interrupt satellite functions.

-- Weapons which could be carried by manned space planes or orbital complexes.

Furthermore, problems of weapon definition are compounded because some non-weapon space systems, including civil and commercial systems, could have characteristics which would make it difficult to frame a definition to distinguish them from weapon systems. An effective space arms control measure should take into account weapon capabilities beyond those of specialized ASAT systems, and at the same time it must not unduly constrain the legitimate functions of non-weapon space systems.

In seeking ways to verify an ASAT weapon ban, the Administration has been confronted with critical definitional problems: (1) there are many different types of systems which could be used to destroy satellites; (2) in general, many activities related to space give rise to capabilities inherently useful for ASAT purposes, for example, the rendevous and docking operations routinely conducted by the Soviets could be used to attempt to conceal development of one or more types of ASAT techniques, and (3) restricting the definition of what is an ASAT weapon could make an agreement easier to verify, but ineffective in achieving

its purpose of protecting satellites. These definition problems interact with and compound the verification problems described above.

Vulnerability of Satellite Support Systems. ASAT arms control would not provide for survivability of all components of space systems. For example, attacks on other elements of a space system (e.g., ground stations, launch facilities, or communications links) may in some cases be easier and more effective than attacks on satellites themselves. Attacks on ground-based support systems can be carried out with strikes by conventional weapons, such as by cruise missiles with conventional warheads launched from ships or aircraft.

The Soviet Non-Weapon Military Space Threat. Examination of space arms control needs to include a discussion of the growing threat posed by present and projected Soviet space systems which, while not weapons themselves, are designed to support directly the USSR's terrestrial forces in the event of a conflict. These include ocean reconnaissance satellites which use radar and electronic intelligence in efforts to provide targeting data to Soviet weapon platforms which can quickly attack U.S. and Allied surface fleets. In view of the fundamental importance of U.S. and Allied access to the seas in wartime, including for Allied reinforcement by sea, the protection of U.S. and Allied navies against such targeting is critical. Furthermore, as Soviet military space technology improves, the capabilities of Soviet satellites that can be used for targeting are likely to be enhanced and represent a greater threat to U.S. and Allied security. This point is explained at greater length below.

III. National Security Considerations Regarding Space

Beyond the significant limitations inherent in space arms control discussed above, other national security interests must be taken into account. These would pertain even if verification were not so significant a concern.

Strengthening Deterrence

A fundamental purpose of defense and arms control policies is to maintain and strengthen deterrence, both conventional and nuclear deterrence. ASAT limitations could, unfortunately, undermine deterrence in some instances.

Since the Soviet Union has an operational capability to destroy satellites while the United States does not, the current situation is destabilizing. If, for example, during a crisis or conflict, the Soviet Union were to destroy a U.S. satellite, the United States would lack the capability to respond in kind to avoid escalating the conflict. Thus, in present circumstances a U.S. capability to destroy satellites clearly responds to the need to deter such Soviet attacks on U.S. satellites in a crisis or conflict.

A comprehensive ASAT ban would afford a sanctuary to existing Soviet satellites designed to target U.S. naval and land conventional forces. The absence of a U.S. ASAT capability to prevent Soviet targeting aided by satellites could be seen by the Soviets as a substantial factor in their ability to attack U.S. and Allied forces and might offset Soviet concerns about the effectiveness of U.S. and Allied naval warfare capabilitiies. Uncertainty over their ability to employ satellites to target naval forces would decrease the Soviet perception of their chance for success, thereby adding to deterrence and stability. A U.S. ASAT capability would contribute to deterrence of conventional conflict.

For US and Allied security, the United States must continue its efforts to protect against threatening satellites. ASAT capabilities complement the other measures that must be used throughout a conflict. To do otherwise would undermine both conventional and nuclear deterrence. (Further discussion of the above factors is provided in the classified version of this report.)

For these fundamentally defensive reasons, the President has called for a prudent, measured response to the Soviet military space threat in order to protect U.S. and Allied security interests. In his National Space Policy statement he said:

> The United States will develop and maintain an integrated attack warning, notification, verification and contingency reaction capability which can effectively detect and react to threats to United States space systems. The United States will proceed with development of an anti-satellite (ASAT) capability, with operational deployment as a goal. The primary purposes of a United States ASAT capability are to deter threats to space systems of the United States and its Allies and, within such limits imposed by international law, to deny any adversary the use of space-based systems that provide support to hostile military forces.

Soviet Threats to U.S. Satellites

The current Soviet ASAT capabilities include an operational orbital interceptor system, ground-based test lasers with probable ASAT capabilities, and possibly, the nuclear-armed GALOSH ABM interceptors, and the technological capability to conduct electronic warfare against space systems.

The orbital interceptor must go into approximately the same orbit as its target and close at a specific velocity. There have been more than a dozen tests of the interceptor system, which we consider operational, including testing during a Soviet strategic forces exercise in 1982.

A Soviet high-altitude orbital interceptor capability is a possible threat, but we have no direct evidence of such a program

by the Soviets, and we may not obtain such evidence before testing. Other techniques for accomplishing this objective may appear preferable to the Soviets. For example, they could also use their developing electronic warfare capabilities against high-altitude satellites. We cannot now say which, if any, such high-altitude capabilities may be developed by the USSR.

Continuing, or possible future, Soviet efforts that could produce ASAT systems include developments in directed energy weapons. We have indications that the Soviets are continuing development of ground-based lasers for ASAT applications. In addition, we believe the Soviets are conducting research and development in the area of space-based laser ASAT systems. We have, as yet, no evidence of Soviet programs to develop ASAT weapons based on particle beam technology.

(Additional data concerning Soviet threats to U.S. satellites are contained in the classified version of this report.)

U.S. Satellites Threatened

While these numerous potential Soviet threats to U.S. satellites must be taken seriously, an immediate need is to address known Soviet ASAT capabilities. The operational Soviet coorbital ASAT system threatens U.S. low altitude satellites. In addition, there is a possibility that some sensors on some U.S. satellites could be damaged by ground-based Soviet lasers. Capabilities which have been or could be surreptitiously developed possibly threaten all U.S. satellites up to geosynchronous orbits. (More data concerning U.S. satellites threatened by Soviet ASAT capabilities are provided in the classified version of this report.)

Options to Counter Soviet Threat to U.S. Satellites

Deterrence provided by a U.S. ASAT capability would inhibit Soviet attacks against U.S. satellites, but deterrence is not sufficient to protect U.S. satellites. Because of the potential for covert development of ASAT capabilities and because of the existence of non-specialized weapons which also have ASAT capability, no arms control measures have been identified which can fully protect U.S. satellites. Hence, we must continue to pursue satellite survivability measures to cope with both known and technologically possible, yet undetected, threats.

Over the past several years the United States has begun to incorporate survivability features into various satellite systems. In addition, the Department of Defense has recently initiated a major review of survivability of not only the satellites but also the communication links and ground systems which support them. The purpose of this effort is to review potential vulnerabilities and to identify further survivability measures for implementation.

Enhancing space system survivability requires a variety of measures. For example, satellite maneuverability helps protect

against ASAT interceptors. Maneuver, however, is a costly tactic in that it shortens satellite mission lifetime and perturbs the satellite's orbital characteristics. Hardening satellites can improve defenses against directed-energy and nuclear weapons, but this tactic provides little effectiveness against a direct nuclear attack. Electronic counter-countermeasures could thwart some electronic warfare tactics directed against U.S. satellites. Another potential survivability measure would be to develop a capability to shoot back at threatening systems. Even more than those options previously stated, shooting back involves a number of severe mission penalties. In sum, these defensive measures add to satellite costs, reduce useful payload weights, shorten mission life time, and add to system development and testing complexity; no single defensive measure is totally effective against all threats.

A different category of defensive measures would involve the use of orbital spares and changing the current U.S. satellite replacement philosophy. By procuring sufficient satellite and booster spares, the United States could persue a launch on demand strategy for the most critical space capabilities. This strategy, combined with the use of stored spares on-orbit, might circumvent the effectiveness of a Soviet ASAT assault. This philosophy runs counter to current U.S. trends of developing space systems of greater sophistication and longer expected useful mission life. In sum, this option would require considerable investment, not now envisioned, in boosters, spacecraft production, launch facilities, and ground support.

The table shows in generic terms the satellite survivability features applicable to potential threats to space systems.

U.S. ASAT Program

The U.S. ASAT system presently under development consists of a miniature vehicle (MV) warhead mounted on a two-stage SRAM/Altair booster. This is carried aloft and launched from a specially modified F-15 aircraft. The MV will be capable of attacking satellites in low altitude orbits. The system is currently undergoing testing. It is to be deployed at one Air Force base on each coast of the United States.

The United States has no plans to extend the altitude capability of the MV ASAT system to place high altitude satellites at risk. We are, however, continuing to review ways in which U.S. ASAT capability could be improved. The U.S. ASAT program is being conducted in a manner fully consistent with all U.S. obligations including the ABM and Outer Space Treaties.

Directed energy weapons technologies, including high energy lasers have the potential for ASAT use. These technologies are in the research and development phase.

(Further data on the U.S. program are contained in the classified version of this report.)

ASAT CAPABILITY	POTENTIAL PROTECTIVE MEASURES				
	Maneuver	Harden/ Shield	Orbital Spares	Replen- ishment	Shoot Back
Coorbital					
Nuclear	X		X	X	X
Non-Nuclear	X		X	X	X
Direct Ascent					
Nuclear	X	X	X	X	X
Non-Nuclear	X		X	X	X
Ground-Based Directed Energy					
Lasers	X	X		X	
High Power RF	X	X		X	
ECM		X		X	
Other Space Platforms with Weapons					
Lasers		X			
Particle Beam					
High Power RF		X		X	
Non-Nuclear	X				X
ECM		X		X	

"X" indicates measures that could be used with varying effectiveness to improve satellite survivability against possible threats. As noted in the text, each defensive measure implies increase in cost and/or significant mission penalties and no single measure is totally effective against all threats.

Utility of a U.S. ASAT Capability

The U.S. ASAT program is focused explicitly on those Soviet satellites which threaten U.S. and Allied terrestrial interests in time of war. All of these threatening Soviet satellites operate at low altitude. Without low altitude satellites to confirm detections of terrestrial targets, Soviet space-based targeting data would be significantly degraded. While the U.S. MV ASAT will be able to attack only a portion of the Soviet satellites, in doing so it would be able seriously to degrade the Soviet reconnaissance capability and thus serves U.S. deterrence objectives. It cannot and need not attack Soviet early warning satellites at high altitudes.

Because of their high launch rates and payload capacity, the Soviet space force has the inherent resiliency to make replacement of satellites a viable alternative (as long as ground facilities are intact). On-orbit spares, surge of launches in a crisis or prior to a hostility, and satellite replacement following ASAT attack are possible methods of replenishment. The U.S. program is structured to provide a number of readily available ASAT systems sufficient to counter expected Soviet surge and replenishment.

Possible Soviet Counters to the U.S. MV ASAT

The U.S. MV ASAT was designed with possible Soviet counters in mind. Maneuvering to avoid intercept is the most frequently discussed countermeasure which the Soviets could employ. It is not clear that the Soviets have the capability to determine which satellite would be the target of a given attack and thus would have to maneuver several of their satellites each time the U.S. launched or simulated the launch of an ASAT interceptor. Because repeated maneuvers would reduce Soviet satellite lifetimes, maneuver would be a costly countermeasure. Although the Soviets could, in the future and at some expense, increase their satellite maneuver capability, this could be offset by U.S. satellite tracking improvements planned for other purposes.

Raising somewhat the orbital altitude of certain existing Soviet low altitude satellites could improve their survivability, but would impair their performance. Only if the Soviets deployed at this new altitude a new targeting capability similar to their existing capability at the lower altitude would the United States need to counter such a capability, for example, by developing a larger booster for the ASAT MV.

Soviet use of simple decoys to improve satellite survivability could be countered by changes in ASAT sensor logic. Complex decoys might require changes in Soviet satellites which could take many years.

Alternatives to Offset the Threat Posed by Soviet Satellites

U.S. force structure plans include a balanced package of complementary defensive measures. The capability to counter Soviet satellites is an important element of those plans. To the extent that we limit our capabilities to counter Soviet satellites, we tend to increase our need to augment our conventional forces to perform their terrestrial missions in the face of the Soviet threat from space, with attending costs.

To counter Soviet satellites by attacking their ground facilities would be an uncertain alternative to an ASAT capability and one which risked escalation of a conflict. A U.S. ASAT capability is a less risky and more effective and flexible way to deal militarily with the Soviet space-based threat.

The ASAT MV compléments other protective measures which must be used throughout a conflict. These measures include communications and emissions security, evasive maneuvers and electronic countermeasures. These countermeasures are, however, reactive and cannot provide permanent protection. Moreover, they can impose sharp constraints on the operational effectiveness of U.S. forces in a conflict.

IV. Arms Control Prospects in Light of Policy and National Security Considerations

The balance between the benefits and risks of ASAT arms control is quite sensitive. For example, there is a dilemma as to whether arms control restrictions that would constrain our ability to deal with Soviet targeting satellites, are in our national security interest. Our need to counter such Soviet satellites so as to support our terrestrial forces must be balanced against our interest in limiting threats to critical U.S. satellites. Our studies of possible ASAT arms control regimes are considering these concerns.

Soviet ASAT Arms Control Activities

Although the Soviets have periodically tested their operational ASAT interceptor, they regularly advance space arms control measures in international fora, without acknowledging their own ASAT capability. In their latest initiative last August, the Soviet Union submitted to the 38th United Nations General Assembly a draft treaty, the stated objectives of which are to prohibit testing and deployment of space-based weapons. It calls for elimination of existing ASAT systems, for a ban on the development of new ASAT weapons, and for a ban on attacks on satellites. The USSR also announced a "unilateral moratorium" on the launching of any type of ASAT weapon, to remain in effect as long as other countries refrain from putting into space ASAT weapons of any type.

U.S. Evaluation of Soviet Initiatives

The wording of these proposals had certain ambiguities and loopholes. For example, it would appear that the moratorium did not cover tests of ground-based systems, such as lasers. In any case, the Soviet moratorium appeared to be designed to block tests of the U.S. miniature vehicle ASAT interceptor, while allowing the USSR to maintain the world's only operational ASAT system. This is inconsistent with the USSR's profession "not to be the first to put into outer space any type of ASAT weapon."

The Soviet initiatives have fundamental shortcomings. Lack of effective verification is one of the major weaknesses of the draft treaty. It provides for national technical means of verification, but nothing beyond that. Indeed, the draft does not even prohibit actions that would impede verification. In addition to the problem of verifying the elimination of the Soviet ASAT system, the draft treaty's proposal for a ban on destruction, damaging, and disruption of other states' space objects could also pose verification problems. The Soviet draft treaty is unclear with regard to Soviet targeting and reconnaissance satellites. The draft also does not deal with residual ASAT capabilities. For example, dismantling of the Soviet co-orbital ASAT system would still leave the USSR the option of using some of its Galosh ABM interceptor missiles in an antisatellite role. In addition, the draft treaty proposes that "piloted" spacecraft not be used for "military purposes." We strongly suspect that this provision is intended to constrain the use of the U.S. Space Transportation System (the Space Shuttle), which in the years ahead will serve as the primary U.S. launch system for national security as well as civil space missions. At the same time, the treaty would apparently not constrain the Soviet unpiloted space station.

Similarly, the possible motives behind the Soviet offer of a "moratorium" are suspect. In addition to their operational ASAT system the Soviets currently have other systems with ASAT capability. The Soviet moratorium deals only with their operational system, allowing the others to continue. For example, the Soviets could test ground-based lasers in an ASAT mode without violating their moratorium. Moreover, the Soviet offer came on the eve of the commencement of flight testing of the U.S. MV system. Thus, the timing suggests that the Soviet offer is designed to curtail the U.S. MV program and thereby leave the Soviet Union with a unilateral advantage in ASAT capability. Furthermore, a test moratorium would not necessarily cause their operational system to atrophy: after a hiatus of several years in ASAT testing, the Soviets were able to resume testing of their ASAT system without any apparent degradation in its performance. Programs in research and development pay a much higher price for a test moratorium. Even a short delay in the test program would delay the time that the U.S. ASAT could be operational. This would decrease the Soviet incentive to negotiate in good faith. (A full analysis of the Soviet draft treaty is provided in the classified version of this report.)

It appears that the Soviet objectives in their initiatives are to limit disproportionately the U.S. ASAT capability and to enhance the Soviet international image.

In sum, it appears that Soviet initiatives on ASAT arms control pose profound verification problems, as in the case of the Soviet treaty, or would leave the USSR with a destabilizing advantage, as in the case of both the treaty and the moratorium.

Multilateral Space Arms Control Activities

The United States has supported discussion of a broad range of questions on space arms control at the Conference on Disarmament (CD). The United States supported in 1983 the establishment of a CD Working Group on Outer Space. The United States does not favor having a working group undertake negotiations. Rather, we believe that a working group should address a broad range of space arms control issues, beginning with a thorough examination of the existing legal regime for space, before any conclusions can be drawn about negotiations which might be pursued in the CD. In 1983, the Soviets insisted that a working group on outer space in the CD be commissioned to begin negotiations. While the United States, our Allies, and the neutral and non-aligned nations of the CD all were ready to establish a working group without authority to negotiate, the Soviets blocked such action. The U.S. position this year in the CD is unchanged: the United States remains ready to proceed with a serious and responsible examination in the CD of space arms control.

Future Directions of ASAT Arms Control

U.S. space arms control policy seeks to reduce the risk of conflict and enhance strategic stability. Consistent with this purpose, the Administration has been evaluating a number of possible ASAT arms control options in light of whether they support our overall deterrence posture and are effectively verifiable. Despite efforts by this and the previous administration, no way has yet been found to design a comprehensive ASAT ban that meets these criteria.

The major problems for ASAT arms control discussed in detail in this report have hindered our efforts to develop effective arms control measures. In fact, it appears that the problems of verification tend to be greater the more comprehensive the limitation. Some less sweeping options under study would seek to limit or ban specific types of weapons systems. Since we must in any event be able to protect our satellites against threats that could be developed without our knowledge, there is a premium on finding ways to limit in arms control those ASAT systems that create the most difficult survivability problems. We are searching for limits on such systems which are effectively verifiable and which allow us to protect U.S. and Allied forces from threatening Soviet satellites, such as targeting satellites. Other options

under examination would regulate certain threatening activities related to space.

The future of space arms control must also be considered in the broader context of U.S.-Soviet arms control relations. Soviet actions in other negotiating fora and Soviet actions with respect to compliance with existing arms control agreements must also be taken into account to determine the most appropriate course of action for the United States concerning arms control for outer space. In the meantime, the U.S. evaluation of possible future courses for ASAT arms control will be judged not simply in light of their ability to limit damage to space objects, but also in light of their contributions to the basic objectives of U.S. arms control policy with respect to terrestrial conventional and nuclear conflict.

The door is not closed to effective ASAT arms control measures. As noted earlier, the President has said that the United States will consider verifiable and equitable arms control measures that would ban or otherwise limit testing and deployment of specific weapons systems, should those measures be compatible with U.S. national security.

This remains the policy of the Administration. The active search for viable arms control opportunities in the ASAT area is continuing.

THE VIRGINIA QUARTERLY REVIEW

Volume 60 WINTER 1984 Number 1

THE MILITARIZATION OF THE AMERICAN SPACE PROGRAM: AN HISTORICAL PERSPECTIVE

By CLAYTON R. KOPPES

The classical era of the American space program has come to an end. After a quarter century in which peaceful and scientific activities played the major role, the space program is veering toward domination by the military. The Reagan administration has given added impetus to this development in two important ways: it has drastically shifted resources from the civilian, scientific side to the military, and it has championed combat capability in space. Planetary missions have become endangered species. But in carrying out this landmark shift, the Reagan administration was able to build on the foundation afforded by crucial decisions in the civilian space program—specifically, John F. Kennedy's impetuous decision to send a man to the moon. The purpose of this article is to sketch the direction of the space program of the 1980's and to analyze the historical developments that prepared the way for this ominous turn from science to a possible "star war."

The first flight of the space shuttle *Columbia*, carrying a

Reproduced with permission of the copyright holder from Koppes, Clayton R. The militarization of the American space program: an historical perspective. Virginia quarterly review, v. 60, winter 1984: 1-20

secret military cargo, was a harbinger of the 1980's becoming the decade of American military exploitation of space. The *Columbia* landed gracefully at the center of a carefully staged media event on July 4, 1982, at Edwards Air Force Base in California. Military brass bands blared, and spectators waved thousands of tiny souvenir stars and stripes on cue. President Reagan helicoptered over from his ranch near Santa Barbara for the 9:15 a.m. arrival of the astronauts, who stayed up for an extra orbit so that the chief executive would not have to be awakened early (a president's sleep is worth millions). Reagan used the occasion to deliver an important address on space policy.

Despite the attention showered on the shuttle, information about its flight was sparse. The Air Force refused to reveal the nature of the cargo, even though one suspected that it wasn't all that secret; the Air Force has maintained a policy of refusing comment on all shuttle cargoes, even weather satellites. A live television broadcast of the crew struggling with troublesome cargo-bay doors was not permitted; instead, film had to be recorded and then cleared by military censors. And when the astronauts finished their work, they received their congratulations from an anonymous official voice.

These proceedings contrasted sharply with a quarter century of relatively open operations under the National Aeronautics and Space Administration. Most early NASA missions were broadcast live; real people could be seen talking, and "no comments" were rare. NASA was established in 1958, in preference to a military-run space program, to give peaceful, scientific ventures an institutional home. The National Space Act of 1958 mandated the "widest practicable and appropriate dissemination of information concerning [NASA's] activities and the results thereof." The space program could not be neatly divided into civilian and military spheres, of course; space exploration had emerged from the military missile programs. The Department of Defense continued to play an important role in space but chiefly with "passive" devices such as surveillance satellites rather than weapons systems.

To Reagan, however, the prime use of space technology appears to be military. The keynote of his 1982 speech at Edwards Air Force Base was the use of space for American defense—in other words, preparation for a combat capability beyond the planet Earth. This was an attempt "to minimize the influence of policy statements extending back to the Eisenhower administration about U.S. peaceful uses of space," noted *Aviation Week & Space Technology*, the weekly Bible of the aerospace industry. Reagan, it said, intended to lessen the barriers between NASA and the military to create "two separate, distinct and strongly interacting programs."

The federal budget reflects these priorities. In 1982 military spending on space technology surpassed civilian expenditures for the first time since the early days of the program. For the next several years, the Reagan administration projects, military space spending will increase about 50 percent more than even the overall Defense Department budget. The space program will thus get an outsized chunk of what may prove to be the most critical legacy of Reagan politics: the shift of federal resources from social services to the military sector.

Planetary exploration—indeed, the scientific aspects of the space program in general—merited scant mention in the president's address. Reagan's lukewarm endorsement of planetary missions suggested that they would have to be squeezed out of budgetary leftovers, if any existed. The hemorrhaging in the federal budget, coupled with the hostility toward planetary programs exhibited by David Stockman and his budget office in 1981, raised widespread alarm that Reagan's speech presaged an end to American exploration of the solar system. Eventually a planetary program survived, but in a scaled-down, low-budget version which underscored the shift of resources to military purposes.

The space shuttle, which NASA grasped as a lifeline in the early 1970's, now epitomizes the growing military dominance of the program. The shuttle idea sat inert on the

launching pad until NASA gained support from the Air Force by promising to make significant design modifications to enhance the spacecraft's military utility. As costs spiraled and capabilities declined in the late 1970's, the shuttle faced further trouble. The Air Force again rode to the rescue, but each Pentagon endorsement carried a higher price tag. Military shuttle missions, once virtually nonexistent, grew to 30 percent of total missions. Now, through 1994, such missions stand at about 50 percent of the total and may well climb more. Yet NASA paid most of the shuttle's costs, and it offers the Pentagon a 32 percent discount from the commercial rate, which is already artificially low. NASA and the Air Force are tight-lipped about the military uses of the shuttle, although one activity may be repair and modification of U.S. satellites in orbit. And NASA has acknowledged, perhaps inadvertently, that astronauts wielding fancy wire cutters could disable twelve hostile satellites in seven days. An Air Force general runs the shuttle program; his executive assistant is an Air Force colonel. Thus the shuttle, once billed as a boon to scientific and commercial operations in space, has become a vehicle primarily for military missions.

Augmented by the shuttle, the Air Force stands on the threshold of realizing its longtime goal of controlling most space activities. In June 1982 it established a Space Command, putting space on an equal footing with the Tactical and Strategic Air Commands. This move clearly anticipates a combat capability. Gen. Lew Allen, Air Force chief of staff, expressed the hope that this new organization would absorb Navy and Army space activities in a single "unified command." Personnel in Air Force blue infiltrate today's NASA. The deputy administrator is Hans Mark, a former secretary of the Air Force. More than 150 Air Force officers and civilian employees are sprinkled through the Washington, Houston, and Cape Canaveral offices. Meanwhile, the Air Force is pouring more than $2 billion into its shuttle facilities, possibly in preparation for its takeover of the shuttle. Secretary of the Air Force Verne Orr remarked in 1982: "Most people in

the Air Force think far enough downstream. We will probably be running the shuttle." Even a name change has been tossed about: the Air Force may become the Aerospace Force.

Whatever its name, the Air Force objective is clear: military domination of the space program before the decade is out. Says Lt. Gen. Richard O. Henry, commander of the space division: "Space is revolutionizing warfare." Accordingly, space is seen as today's equivalent of the age-old military objective of the "high ground." For now, the Pentagon emphasizes upgrading "passive" uses—communications, surveillance, navigation, and weather forecasting. The defense satellite communications system, a network of ten orbiting satellites which soon will be augmented with a new generation of satellites at $50 million apiece, handles military and government communications worldwide. An 18-satellite global positioning system about to be deployed will allow receivers anywhere—even on man-carried packs—to tell their location within 1/100th of a mile. The system can also guide ballistic missiles with uncanny precision. The Reagan administration wants to spend nearly $20 billion over the next five years to expand and harden the network—much of it in space—for directing nuclear forces. These communication links assume particular importance for the newly fashionable notion of fighting a protracted nuclear war.

For the future, some politicians and Pentagon planners dream of real-life "Star Wars," with flashing lasers, particle-beam weapons, and the like. The president raised this possibility with his "Darth Vader" speech in March 1983—a technological companion piece to his "evil empire" ideological manifesto delivered a short time earlier. Reagan apparently envisions a network of orbiting satellites equipped with lasers that could destroy Soviet missiles within a few minutes of launch. He presented this scenario in the most hopeful of terms; this deployment would rescue Americans from the scourge of nuclear weapons. The militarization of space presumably would become the path to perpetual peace.

The president was responding to the deep-seated fear of nuclear war. But his prescription feeds the dangerous illusion that there is a defense against nuclear weapons. By focusing on a technological fix, this approach distracts energies from the key problem: dealing with the nuclear weapons themselves. Far from lending stability to the nuclear equation, the Reagan net may heighten the possibility of nuclear war. Once a hostile nation's incoming missiles were destroyed, the United States would have the option of launching its own nuclear strike undeterred by fears of retaliation. The Soviet Union would therefore have every incentive to knock the American lasers out of the sky or develop countermeasures, with all the risks such moves would entail.

But even apart from such considerations, it is doubtful that the Reagan lasers make strategic sense. Except for the Edward Teller coterie, most scientists treated the Reagan speech with skepticism or derision. They point out that the technological problems of crafting a system that would work with the necessary precision are probably insuperable. The logistical demands are formidable; perhaps 2,000 shuttle flights would be required to transport the heavy mirrors and the like into space. What is more, many scientists and arms experts, such as Harold Brown, President Carter's secretary of defense, argue that countermeasures would be easier and cheaper. This new space arms race could fuel a spiral of ever more arcane and dangerous, but inconclusive, technology. And it would entail the expenditure of untold billions. Brown thinks that Defense Department budget limitations will eventually derail any such project. "But it is less clear," he says, "that its enthusiasts can be prevented from spending some billions of dollars in a fruitless attempt."

Like the bomber and missile gaps of yore, the military turn in space is being sold as a response to the Soviet Union's transgressions. Familiar tactics, such as calculated leaks, distorted statistics, and lurid future possibilities, are prominent again. A pattern of the post-World War II arms race is repeating itself. Herbert York, onetime director of the Liver-

more Laboratory and the Defense Department's chief scientist, believes the United States bears a major responsibility for the arms race. In most areas of weapons development, it has long been ahead of the Soviet Union; in those where it has been behind, the scope and pace of the American response has triggered a new round of escalation. John Foster, former director of Pentagon research and engineering, candidly observed that two forces drive American military research and development: "Either we see from the fields of science and technology some new possibilities which we think we ought to exploit, or we see threats on the horizon, possible threats, usually not something the enemy has done, but something we have thought of ourselves that he might do, and we must therefore be prepared for." In short, the role of perception is crucial; rather than simply responding to the Soviet Union, the United States has usually held the initiative.

However alluring space as the complete battlefield may be to some enthusiasts, the United States has much to lose should space become an arena of active combat. America is ahead in military space technology, but it is more dependent on space-based systems than the Russians, who enjoy a geographically central position. The obvious alternative is a treaty that would ban antisatellite (ASAT) weapons. ASAT negotiations were sluggish in the late 1970's and collapsed after the Soviet invasion of Afghanistan. A group of prominent scientists and arms experts have appealed to the Reagan administration to resume negotiations on a treaty banning space weapons. The group includes men such as Lee DuBridge, former head of the California Institute of Technology and presidential science adviser, and William Pickering, the veteran director of the Jet Propulsion Laboratory who played a major role in forging the close relationship between science and the military during the Cold War. They warn that this is "close to the last moment" to keep space free of weapons. Once weapons are deployed there, it may prove all but impossible to remove them. If an ASAT treaty proves unat-

38-036 O - 84 - 72

tainable, Brown suggests at least trying to get two lesser goals: a declaration that "attacks on satellites are a hostile act prohibited in peacetime" and a "limitation—for example, to low altitudes—on development and deployment of anti-satellite capabilities."

The Reagan administration shows little interest, however, and recently reacted to a Soviet proposal for an ASAT treaty with indifference, if not contempt. It believes that massive military buildup is desirable in itself because of the strains such competition places on the Soviet economy. Arms control chief Kenneth Adelman stresses the problem of verification. This is a serious issue, to be sure. But the problem of verification curiously evaporates whenever the Pentagon, campaigning for new weapons systems, presents as gospel its charts and graphs of Soviet current strengths and future possibilities. As a result, in the words of the Center for Defense Information, "the race to militarize space is rapidly outpacing the modest diplomatic efforts to control it."

II

Whatever the future price of military space programs, a major cost already has been a reduction in our ability to explore the solar system. The most notable casualty has been planetary exploration—the brilliant series of missions to the terrestrial planets and beyond whose scientific returns provide perhaps the ultimate rationale for the space program. As the voracious shuttle consumed the NASA budget, important scientific missions wound up on the budget room floor, in particular the once-in-a-lifetime opportunity to intercept Halley's Comet in 1986 and the American spacecraft for the International Solar-Polar Year. At one point it appeared that David Stockman might even pull the plug on the *Voyager* mission enroute to Uranus and leave it to telemeter its path-breaking data back to a deaf Earth. Other nonmilitary programs, including space applications and aircraft research, have been severely cut.

The Jet Propulsion Laboratory in Pasadena, the world leader in planetary exploration, has converted to about 30 percent military funding after two decades of virtually no classified work. After retiring as Air Force chief of staff, Lew Allen became director of JPL on Oct. 1, 1982. Allen, who holds a Ph.D. in nuclear physics from the University of Illinois, is the first director from outside Caltech, JPL's nominal manager. He insists that JPL will retain its planetary and scientific ethos. But the Pentagon has captured a portion of the laboratory's activities permanently, with Caltech promising that JPL will not renege on its military contracts even if there should be a resurgence of civilian funding.

In the uproar over the 1981-82 budget cuts—"a lot of bad vibes and a lot of good dialogue"—modest signs of hope began to surface in late 1982. Planetary scientists and NASA officials mapped plans for new missions. The 1983 NASA budget proposal included the first new start since 1977, the Venus Radar Mapper. This mission is the half-price cousin of the $600-million Venus Orbiting Imaging Radar (VOIR). The arbitrary price cut significantly reduced scientific returns. Instead of 0.1-kilometer resolution over the whole planet, the new project offers 1-kilometer resolution over 70 percent of Venus. If approved during the 1983 budget cycle, Venus Radar Mapper could orbit the mysterious inner sphere by late 1988. "But whatever happens," observed M. Mitchell Waldrop in *Science,* "the mission does seem to represent a good-faith effort to give the Administration what it says it wants: high-payoff science at a minimal cost."

Even on the narrow grounds of national interest, this policy is shortsighted. As Harold Brown has pointed out: "At a time when U.S. technology is one of the few comparative advantages that this nation has, and one of the few instruments of American prestige and morale, it is foolish to let the space science and planetary exploration programs wither." The odds are high. For, if the new cut-rate missions cannot save the scientific and planetary side, in Brown's opinion, "it is

likely that the ability to carry out such programs will be lost for the rest of this decade."

Although the Reagan administration has made the trends to space militarization starkly clear, an historical perspective suggests that this military domination developed during the past 20 years—and is in large part due to NASA itself. The choice that set NASA on a trajectory so damaging to the civilian side was the decision to gamble most of its chips on the shuttle. That choice derived, in turn, from what might be termed the Apollo imperative: the necessity of finding a project big enough and costly enough to absorb at least some of the capacity created for Apollo.

The early years of the space program, under the Eisenhower administration, suggested an alternate approach that might have achieved many of the goals of Apollo but at less cost and with less long-term harm to the civilian space program. Established in 1958, the fledgling NASA embarked on a cautious course that tried to downplay "spectaculars" and keep science in the foreground. Heading the new agency was T. Keith Glennan, president of Case Institute of Technology in Cleveland and a former member of the Atomic Energy Commission. Glennan believed that the United States could not avoid competition with the Soviet Union in space, but he wanted to establish the terms of the competition. No "space cadet," he thought that putting a man on the moon was worthwhile, although not "a matter of prime importance." He favored a program with a budget of $2 billion to $2.5 billion per year that would make possible a manned lunar landing by about 1975. The preoccupation with prestige had little place among his priorities. For Glennan, American leadership involved much more than primacy in space. As he confided to his private diary: "When one starts to talk about the prestige of the United States resting on the question—'When do we get a man on the moon?'—it seems clear that all sense of perspective has gone out the window."

NASA under Glennan started a cautious man-in-space program, known as Mercury. The first astronaut, Alan Shep-

ard, lofted into space for a few minutes on May 5, 1961, became a national hero, although he did little more than go along for the ride. Glennan worried about the "circus" atmosphere surrounding the astronauts. Eisenhower, even more skeptical, was prepared to call for an end to the manned program in his last budget message, in January 1961. He chose less-categorical language, however, and still put science first: "Further testing and experimentation will be necessary to determine whether there are any valid scientific reasons for extending manned spaceflight beyond the Mercury program."

III

In retrospect, the civilian space program established under the Eisenhower administration appears ideal. It put peaceful, scientific goals first; it showed a healthy skepticism about the exaggerated profits of prestige. If putting a man on the moon was worthwhile, surely Glennan's step-by-step approach was preferable to the crash program actually undertaken. His plan allowed for a careful, evolutionary process rather than the exorbitant costs entailed by Apollo's concurrency—the development of new technologies simultaneously rather than in sequence. His plan also avoided the creation of a large extra capacity that would establish a momentum for additional Apollos after it was finished. Above all, it recognized that, as James R. Killian, Eisenhower's first science adviser and the president of MIT said, "the really exciting discoveries in space can better be realized by instruments than by man."

Any loss of prestige in the race to space by the United States was partly self-inflicted. Ironically, the U.S. obsession with getting ahead of the Soviet Union offered its adversary an advantage, as Glennan realized. After leaving office in January 1961, the NASA official suggested what Soviet leader Nikita Khrushchev could do—and, in fact, did: launch "a barrage of propaganda and successful spaceflights until he had the U.S. committed to a costly program"—and "then

withdraw from the 'race.' " Glennan's intuition was shrewd. Although some people believe that, because of its greater resources, the United States can easily outspend the Russians, the opposite may be more accurate. America's bountiful resources can create the illusion that all things are possible and, hence, that difficult choices need not be made. This illusion has come to haunt us since the spending sprees of the 1960's.

The spending spree on space projects began in earnest soon after John F. Kennedy became president in early 1961. To Kennedy, the "space gap" symbolized "the nation's lack of initiative, ingenuity, and vitality under Republican rule," according to his confidant Theodore Sorensen. "The President was more convinced than any of his advisers that a second-rate, second-place space effort was inconsistent with this country's security."

Other New Frontiersmen were more cautious. David E. Bell, the former Marine and Harvard economist who served as budget director, tried to put the space program in perspective. He objected to "full-scale participation in the 'weight lifting' and manned space-flight competitions." These activities impinged on other, more worthwhile parts of the budget. He argued for a strong scientific and technological program, as well as for space applications such as meteorology and communications. These would be at least as effective in building prestige, for they were "a specific token that we are more concerned with the problems of *men on earth* all over the world than we are with placing *men on the moon.*"

Kennedy ignored these balanced assessments, however, when he faced a disastrous week in mid-April 1961. On April 12 Soviet astronaut Yuri Gagarin became the first man to orbit the earth. Then on April 15 the Bay of Pigs invasion of Cuba began, and by April 19 the White House knew the operation was a fiasco. On that day Kennedy called Vice-President Johnson into the Oval Office and told him to find a "space program which promises dramatic results in which we could win." A few days later Johnson came back with the impro-

vised proposal for Apollo—a program to put a man on the moon by the end of the decade at a cost close to $35 billion—a price tag the Eisenhower administration had considered outrageously wasteful. Kennedy presented the Apollo project to a receptive Congress on May 25, 1961. Invoking familiar New Frontier Cold War imagery, he called Apollo essential "if we are to win the battle that is going on around the world between freedom and tyranny."

More than prestige was at stake. An aggressive man-in-space program enhanced American military prowess—one of the major goals of the Kennedy administration. The New Frontier fashioned what Sorensen proudly termed "the most powerful military force in human history—the largest and swiftest buildup in the country's peacetime history." The expansion ranged from counterinsurgency forces, such as the Green Berets, to the huge Minuteman missile fleet. NASA's manned activities not only furthered "the peaceful conquest of space but also helped create the building blocks for the future military missions which may be required," said Gen. Thomas S. Power, commander-in-chief of the Strategic Air Command. NASA estimated that three-fourths of the cost of Apollo went toward development of near-Earth orbital capabilities, which were essential for possible military missions, such as interception of "hostile space vehicles." NASA also financed most of the cost of the development of large launch vehicles and complex ground facilities. All these "building blocks" would be assembled for the shuttle and its military uses in the 1980's.

Although the Apollo program sped through Congress, most scientists were skeptical because Apollo seemed likely to produce relatively little scientific data in comparison to its enormous cost and yet was presented to the public as a scientific undertaking. The elder statesman of American science, Vannevar Bush, who had run the Office of Scientific Research and Development during World War II, pointed out that national prestige was "far more subtle" than NASA's "immature" concepts. He preferred a different Kennedy

innovation, the Peace Corps: "Having large numbers of devoted Americans working unselfishly in undeveloped countries is far more impressive than mere technical excellence," he said. Glennan presciently noted in private that the feverish excitement attached to the Apollo program "in the long run . . . could work strongly to our detriment."

IV

In the short run, Apollo promised a Christmas tree laden with treats. Since the shift from bombers to missiles threatened the stability of the aircraft industry, a big space program was a godsend. A senior engineer at JPL observed that the companies argued that "our country is plagued with being too efficient in its production for its own economic good, and hence that inefficient production such [as] is generated by making planes or missiles that will in all probability never be used is essential to economic stability." He observed sardonically of the space program: "It is certainly possible to spend large sums of money in inefficient production in this area."

Apollo enjoyed an ardent advocate in Kennedy's NASA administrator, James E. Webb. A dynamic capitalist Cold War warrior, Webb epitomized the post-World War II American businessman who shuttled between corporate board room and government suite. He served as President Truman's budget director and under secretary of state, then went on to run one of Oklahoma Senator Robert Kerr's oil companies and sit on the board of McDonnell-Douglas, the giant aerospace contractor. Webb stressed the quasi-military aspects of the space program in relation to the Cold War. He warned that "the population not adequately disciplined to carry out large-scale organized efforts, such as are required in wartime, and which are now manifest in the space program, . . . may be subject to the disintegration" that afflicted Rome. Webb skillfully forged an alliance of Sunbelt politicians and the politically potent aerospace firms. Most of the space business went to the Sunbelt. The Johnson Manned Space Center, for

example, landed in Houston, the home district of Congressman Albert Thomas, who chaired the House committee controlling NASA's budget. Webb wooed industry with a profusion of multi-billion-dollar contracts. "The result," *Fortune* concluded, was "an intimate new sociology of space, a new kind of government-industrial complex in which each penetrates the other so much that sometimes it is hard to tell which is which."

Apollo grew to dominate NASA. It took the lion's share of the budget, and its presence distorted other aspects of the space program, particularly the scientific projects. Ranger and Surveyor, two lunar precursors of Apollo, for instance, had mainly scientific objectives. Yet when the NASA budget got tight, in the mid-1960's, the last blocs of Ranger and Surveyor missions, which would have made possible a complete mapping of the moon, were canceled so as not to jeopardize Apollo.

The project reached its goal when Neil Armstrong took his "giant step for mankind" from the *Eagle* in July 1969. Apollo was an engineering landmark, as $30 billion projects tend to be, and it was not without its benefits for science. Nevertheless, the $30 billion showered on Apollo could have returned immeasurably greater scientific knowledge had it been applied to instrumented space exploration. And, ironically, the United States could not fully savor Apollo's expected dividends for national prestige since some of the same fixations about Communist advancement that had produced Apollo also plunged the United States into Vietnam. Much of the prestige America hoped to gain on the surface of the moon had already been lost in the jungles of Southeast Asia by the summer of 1969.

Now that Apollo had reached home port safely, what next? The public might remember Neil Armstrong, but would it remember the third astronaut on the moon, or the fifth? What would NASA, and the firms it had wooed, do for an encore? The "new sociology of space" had ominous long-term implications. The huge buildup of plant capacity, the throngs of

aerospace engineers who needed jobs, and the bureaucratic drives of a typical federal agency all created a momentum to find a program to fill Apollo's shoes.

One idea was to apply Apollo technology and scale to the planetary program. NASA promoted *Voyager*, a giant orbiter-lander combination larger than any planetary spacecraft designed to date, for a mission to Mars in 1973. The weight of the spacecraft would be almost enough to accommodate a manned mission to the red planet—a not-so-secret wish of some space enthusiasts. The Voyager project would cost at least $2 billion and would allow NASA to boost the cost of the planetary program from the range of $50 million to $500 million annually. That high cost was Voyager's chief recommendation, for it would keep cash flowing through the Apollo political pipeline. Some second-level NASA managers doubted Voyager's technical feasibility. Most scientists disputed its merit. Only one American spacecraft had visited Mars, *Mariner 4* in 1964. Gambling everything on one big Voyager in 1973, NASA wanted to pass up opportunities to launch smaller missions in 1966, 1969, and 1971. NASA had gotten the mission backwards. James Van Allen, chairman of the space science board of the National Academy of Sciences, expressed his panel's opposition in colorful, if sexist, language: we should send "a number of well-equipped scouting parties to the several planets before we send out the wagon train with all of our women and children and a full set of household furnishings." Lacking a make-believe Mars race but facing a real war, NASA could not sell Voyager to Congress.

V

Until now science had been tailored to technology. With the demise of Voyager, it was possible to make technology serve science. When the future of the space agency was being debated in the late 1960's, physicist Ralph E. Lapp proposed a scientifically oriented space program with a budget of $1.5

billion to $2 billion per year. The planetary program that actually emerged, at first under the shadow of the manned side and then on its own in the 1970's, stands as a model of how the space program might be conducted.

The highlights of this program were the planetary missions run by the Jet Propulsion Laboratory, starting with the United States' first successful planetary mission, the Mariner flight to Venus in 1962. JPL launched seven successful *Mariners,* which were designed to make flybys of planets—two to Venus, four to Mars, and one which used a dramatic gravity-assist technique to visit Venus and then Mercury three times. In 1976 the Viking orbiter-lander, much smaller than that proposed for Voyager, carried the eagerly awaited life-detection experiments to the Martian surface. And in 1981 a completely reoriented and scaled down *Voyager* sailed beyond the terrestrial planets to Jupiter and Saturn and then headed for a rendezvous with Uranus in 1986. These missions were augmented by the small Pioneer missions, which made preliminary reconnaissance visits to the planets.

The planetary missions were relatively inexpensive. The *Mariners* actually declined in cost, despite the stiff inflation of the late 1960's and early 1970's. The 1969 *Mariner* cost $127 million, *Mariner* 1971, $133.5 million, but *Mariner* 1973, $98 million. With the *Mariners,* NASA first imposed cost as a discipline. Previously, two senior officials noted, NASA "stressed technical performance and schedule requirements over cost as a discipline." This was, of course, an indirect admission that NASA had been willing to pay pretty much whatever it cost in order to attain high technical standards under tight schedules. *Mariners* had the advantage of being evolutionary; these spacecraft were for the most part developed in sequence instead of concurrently, as in the Apollo program. Each mission also made greater use of designs from previous missions, which greatly reduced costs. Even Viking, which posed new problems because it had both

an orbiter and a lander equipped for complex biological experiments, cost less than $1 billion, despite inflation.

Still, with a relatively small expenditure of money, the planetary program made possible an intellectual revolution in our understanding of the solar system. The planets were realms of mystery before the space age. Now many of the surface and atmospheric features are well known: the multihued rings of Saturn, the volcanoes of Io, turbulent Jupiter, the red deserts of Mars, and the furious temperatures and intense atmospheric pressure which make Venus a "hellhole of a planet."

But perhaps the greatest legacy of the planetary explorations was a more subtle one—a gradually shifting view of the theory of the origins of the planets "from a cold birth to a hot one." Older notions held that the planets had accumulated while cold and that they were homogeneous, becoming differentiated later. Now it is believed that the planets accumulated while hot and that their differentiation occurred during the accretion period. Moreover, Earth's geological history, once studied in isolation, now stands in a new relationship with the other planets of the inner solar system. As scientists Bruce Murray, Michael Malin, and Ronald Greely said: "New insights are developing that link the Earth, including the very atoms that compose its sentient beings, with the origin and evolution of those other four planets . . . in a common planetary environmental history." This intellectual revolution represented the most profound achievement of the space program and provided its most cogent rationale.

This model of NASA—devoted to scientific and planetary missions plus some traditional activities such as aircraft research—probably could have maintained its balanced, relatively low-budget program for some time. The agency's appropriations totaled about $3 billion in the early 1970's, compared to almost $6 billion in fiscal year 1966, the peak of Apollo funding. But NASA, and the depression-ridden aerospace industry, sought a return to large-scale projects. Thom-

as O. Paine, NASA administrator from 1968 to 1970, wanted to "swashbuckle," as he put it to his intimates. NASA faced, though, a crisis of legitimacy with Congress and with Nixon's budget bureau, and Paine's grandiose plans got nowhere.

Paine's successor, James C. Fletcher, who headed NASA from 1971 to 1977, found the key to rebuilding his budget and reinvigorating the alliance with industry and the military through the space shuttle. Besides keeping alive the glamour of man in space, the shuttle was sold on the grounds of economy and practicality. The shuttle was supposed to be economical because it is a reusable vehicle. Its practicality came from its multipurpose nature: not only scientific and military missions could use it but commercial ventures as well for such activities as manufacturing precision objects in the more favorable environment of space. The shuttle's success was contingent on an economical, relatively trouble-free development.

Just the opposite occurred. Its development took longer and cost much more than anticipated; the number of missions that appeared to be feasible declined. The shuttle's turn-around time was slower than anticipated. Whipsawed between high development costs and reduced future prospects, the shuttle is falling far short of its original projections for commercial and scientific use. In their stead military domination looms.

The price for the shuttle was more than money. "NASA mortgaged nearly everything—science, space exploration, the development of new technologies—to build the space shuttle on what was a shoestring budget, as big Government projects go," said John Noble Wilford, the *New York Times* science writer. The planetary budget, adjusted for inflation, was slashed by a factor of four from 1974, when Viking expenditures topped out, to 1977. From then through 1982 the planetary slice floated between $200 million and $300 million annually (in 1982 dollars). That sum had to carry all the planetary activities, including Voyager, the Pioneer Venus mission, Galileo development, and the Deep Space

Network. There were no scraps for new missions. Faced with the Reagan budget cuts of 1981 and 1982, NASA chose what Wilford termed "bureaucratic triage." It saved the shuttle "by killing off most other projects." *Columbia* rose into orbit "from the ruins of the nation's civilian space program."

Some NASA officials argued, to be sure, that the shuttle would eventually benefit planetary exploration. But William Pickering, like most people involved in space science, was dubious. He preferred launching from "a good, solid launching site in Florida" to blasting off from "a moving platform in space." So long as spacecraft continue to weigh about a ton, existing technology is adequate to reach even the comets and asteroids, whose "primitive, undisturbed material" possesses great importance for understanding not only the origins of the solar system but all stars. As JPL scientist Arden Albee put it: planetary science's coexistence with the shuttle is like "being in a lifeboat with an elephant."

Planetary exploration and space science generally face a decade of tenuous existence as the militarization of the American space program gathers force. The emerging space program of the 1980's contrasts sharply with the program's first quarter century. During this classical era, exploration and scientific inquiry predominated over military considerations. Space became a new peaceful theater of intellectual experience as man gained a sense of unity with the solar system in which he lives. But space, once touted as an escape from or sublimation of Earth's quarrels, now looms as an extension of terrestrial hatreds. As 1984 begins, choices are being made that threaten to open a dangerous, expensive, and new phase of the arms race in the once peaceful vastness of space.

Space Weapons Policy

He Who Decides a Case Without Hearing the Other Side . . . Tho He Decide Justly, Cannot Be Considered Just—SENECA

FOREWORD=

MILITARY USAGE HAS LONG BEEN a feature of U.S. space policy. Although the civilian and military space programs are administered separately, there are inherent technological inter-relationships. Launch rockets, for example, boost both civilian satellites and ICBMs.

A vast array of small orbiting communications satellites are launched routinely. Some of these form an integral part of both U.S. and Soviet defense structures. They range from devices for communications with land, sea and air forces to those for the monitoring and verifications of arms control agreements. The satellites are both vital and vulnerable.

The Soviet development of an operational antisatellite (ASAT) capability has led to a U.S. policy that military space systems "be designed, developed and operated to enhance the survivability and endurance of critical mission functions." Since 1977 this policy has included the development of a non-nuclear ASAT capability "to deter threats to space systems of the United States and its allies and threats from space systems supporting hostile military forces."

The U.S. ASAT program has become one of the principal elements in the current controversy over U.S. space weapon policy. The program has technological features which are subject to dispute as to feasibility and cost. The ASAT weapons system also relates to existing treaties concerning space weapons, arms control, and nuclear war prevention.

A series of talks with the Soviet Union on ASAT weaponry, held during the Carter administration, was cancelled following the invasion of Afghanistan. Opponents of U.S. deployment of ASAT weapons take the position that the program should be restrained pending resumption of U.S.-Soviet negotiations, to avoid an "arms race in space."

Proponents take the view that the Soviets have long had an ASAT capability which the U.S. must have also.

Another program that has become a major element of the current controversy over space weaponry involves a system intended to knock down attacking nuclear missiles while in flight. Antiballistic missile weaponry not only has its own technological features, controversial as to cost and feasibility, but its own relationship to treaties and nuclear war prevention strategy.

For some two decades the principle of "mutual assured destruction" has been a feature of U.S. nuclear war deterent policy. This holds that so long as the Soviet Union and the United States each has the capability to destroy each others' population centers neither will do so. Another policy facet involves "theater nuclear forces." Their purpose in Europe has been not just to avoid nuclear war, but to deter any conventional war that might become nuclear. Unable to determine the general geographic location of where or how NATO could defeat the Soviet army with conventional forces, theater nuclear weapons have long been deemed essential by NATO.

The antiballistic missile defense concept would, its proponents maintain, add a new strategy dimension by mitigating the damage potential of Soviet nuclear weapons. Opponents believe that such an ABM system would be destabilizing, in that it would shift the "balance of terror" by denying in whole, or part, the Soviet ability to strike the United States, thus accelerating the arms race, and rendering obsolescent existing arms control concepts.

Complicating policy decisions on space weaponry, as well as strategic, theater, and arms control concepts, are constantly emerging technological factors, such as lasers and others which play an obscure but vital role in weapons systems.

The Congress in reaching such decisions must contend with a complex technology, much of which is being developed outside the military but has a scientific impact upon it.

Current U.S. Space Policy

DIVISION OF THE U.S. SPACE PROGRAM into separate military and civilian components was established by President Eisenhower.

NASA

The National Aeronautics and Space Act of 1958 created the National Aeronautics and Space Administration (NASA) to conduct civilian space activities. It assigned military space programs to the Department of Defense (DOD).

Reagan Policy

On July 4, 1982, President Reagan released his administration's space policy for both military and civilian programs. One goal called for the strengthening of U.S. security. The new policy directive stated that "survivability of space systems will be pursued commensurate with the threat, with the planned use in crisis and conflict, and with the availability of other assets to perform the mission"; and the United States will develop an antisatellite (ASAT) system both to deter threats and, "within such limits imposed by international law, to deny any adversary the use of space-based systems that provide support to hostile military forces." The President stated that military and civilian programs will continue to be separate entities. He outlined guidelines for cooperation between the two.

In August 1982, DOD released a Fact Sheet outlining a new defense space policy. DOD and NASA will continue to cooperate under existing agreements on the terms of the President's space policy message. DOD recognizes the Space Shuttle as the country's primary launch system "and the need for the DOD to continue to cooperate with NASA efforts to develop a fully operational Space Transportation System."

Regarding weapons in space, the Fact Sheet stated that the development of an ASAT capability will continue "within such limits imposed by international law" and added that DOD planning "emphasizes adherence to the existing international legal regime which pertains to space" and that DOD will "consider verifiable and equitable arms control measures that would ban or otherwise be compatible with United States national security." The new policy contains "no new directions in space weaponry," but provides support for continued research.

Missile Defense System

In a televised address to the Nation on defense policy on March 23, 1983, President Reagan stated in part:

"Up until now we have increasingly based our strategy of deterrence upon the threat of retaliation. But what if free people could live secure in the knowledge that their security did not rest upon the threat of instant U.S. retaliation to deter a Soviet attack; that we could intercept and destroy strategic ballistic missiles before they reached our own soil or that of our allies?

"I know this is a formidable technical task, one that may not be accomplished before the end of this century. Yet, current technology has attained a level of sophistication where it is reasonable for us to begin this effort. It will take years, probably decades, of effort on many fronts. There will be failures and setbacks just as there will be successes and breakthroughs. And as we proceed we must remain constant in preserving the nuclear deterrent and maintaining a solid capability for flexible response. But is it not worth every investment necessary to free the world from the threat of nuclear war? We know it is!"

Reagan on ASAT

The Reagan Administration established an Intergovernmental Group to review and study ASAT policy.

President Reagan reaffirmed the U.S. commitment to pursue an operational ASAT system. His July 4, 1982, statement further emphasized U.S. space policy commitment to the ASAT program "with operational deployment as a goal."

The policy statement identified the primary purpose of the ASAT system as deterring threats to space systems and denying "any adversary the use of space-based systems that provide support to hostile military forces."

In August 1982, the Defense Department further released an unclassified fact sheet outlining space policy. The policy directs the continued development of an ASAT "within such limits imposed by international law," adding that DOD planning emphasizes "adherence to the existing international legal regime which pertains to space" and that DOD would "consider verifiable and equitable arms control measures that would ban or otherwise limit the deployment of specific weapons systems should those measures be compatible with United States national security."

38-036 O - 84 - 73

Treaties Involved

A NUMBER OF TREATIES currently affect international military activities in space.

Both the Limited Test Ban Treaty of 1963 and U.N. Outer Space Treaty of 1967 forbid the placing of nuclear weapons in space. In 1972, the Treaty on the Limitation of Anti-Ballistic Missile Systems prohibited interference with "national technical means of verification," referring to reconnaissance satellites. The ABM accord also prohibits development, testing or deployment of space-based Anti-Ballistic Missile systems. Although systems based "on other physical principles" are open to further discussions.

Carter Limitation Talks

President Carter announced during a press conference on March 9, 1977, that he had consulted the Soviet Union about arming satellite bodies and also "to forego the opportunity to destroy observation satellites." Three rounds of ASAT limitation talks were then held but the Soviet invasion of Afghanistan in December 1979 chilled arms control talks.

The United States wanted the discussions to include a treaty to stop ASAT tests. A major U.S. objective was the dismantling of the Soviet Union's ASAT system and to provide for verification.

Soviet Treaty Proposals

On August 11, 1981, the Soviet Union submitted to the United Nations a draft treaty, calling for a ban on the stationing of weapons in space. It was referred to the Committee on Disarmament. No action was taken.

Nine U.S. Senators visiting Moscow met with Soviet Premier Andropov on August 18, 1983. The Premier expressed concern about space weapons. He urged a "complete prohibition of the testing and development of any space-based weapons for hitting targets on Earth, in the air or in outer space." Premier Andropov committed the Soviet Union "not to be the first to put into outer space any type of anti-satellite weapons," as long as other nations "refrain from stationing in outer space antisatellite weapons of any type." Although he did not admit that the U.S.S.R. possesses an ASAT system, he did appear willing to suspend its testing and discuss possible dismantlement, in exchange for American commitments not to station similar weapons in outer space.

A revised Soviet draft U.N. treaty was introduced on August 22, 1983. This differed substantially from their 1981 proposal. The new treaty placed a ban on the use of force in outer space. It also called for dismantlement of all existing ASAT systems, though the Soviet Union denies it has developed such a system. Other provisions prohibit the use of manned spacecraft for military purposes or to launch military satellites. It was referred to the U.N. First Committee and from there to the Committee on Disarmament. On November 25, 1983, the United States was the only nation in the First Committee to vote against a resolution urging negotiations on a treaty to ban space weapons. The vote was 120-1. Only the United Kingdom abstained. The U.S. said it was "not ready to negotiate at this time."

Verification Concerns

Verification is said to be the biggest obstacle to an ASAT accord. The difficulty is over exactly what draft treaties might prohibit: development, testing, possession, deployment, or use; or demands, such as the dismantlement of existing systems. Only the Soviet co-orbital system is presently considered operational. It is likely to become the cornerstone for any future ASAT treaty discussions. In the case of the U.S. F-15 ASAT, the Soviet Union would have difficulty in verifying development and testing, particularly since the American system is small and can be placed on any F-15. While the Soviet ASAT can be launched from only two available launch sites and requires large and relatively easily detectable rockets.

Use of an ASAT system is not always easy to detect. Problems could arise if the Soviets perfect a single-orbit interceptor. Since distinguishing between a malfunctioning satellite, one hit by space debris, or a satellite attacked by an ASAT is extremely difficult.

Verification difficulties could also be encountered if testing is not banned. For example, the SS-9 is used to launch Soviet ASATs and for launches of radar-ocean reconnaissance and electronic-ocean reconnaissance satellites. U.S. ability to verify a payload on an SS-9 is classified. Some measures to assure that an ASAT is not being carried by an SS-9 will have to be made.

Still other difficulties might arise if changes are made to Soviet ASAT test patterns.

Assurances that existing systems will be dismantled and

(Continued on page 96)

Space Weapons Systems

THE PRINCIPAL SPACE WEAPONS SYSTEMS involve antisatellite and ballistic missile defense capabilities.

ASAT

The term "antisatellite" or ASAT, refers to a weapon system used to destroy Earth-orbiting satellites.

Devices can be ground-based, placed on airplanes, or used in outer space. Both ground- and air-based weapon systems include:

(1) direct launchings of missiles carrying nuclear or nonnuclear warheads;

(2) co-orbiting devices with explosive warheads; or

(3) a direct-energy (laser) weapon.

Conventional Weapons

Non-nuclear ASAT systems involve explosive devices or impact vehicles. Here an "interceptor" would maneuver close to its target so that exploding shrapnel from the interceptor would destroy the target. According to one plan, an interceptor could be launched to attack an enemy satellite at a specified time. Or it could be launched into orbit to be activated when needed (known as a "space mine"). Impact vehicles require accurate targeting mechanisms to crash the interceptor directly into the enemy satellite.

Nuclear Devices

Nuclear warheads have a large "kill radius," which is an advantage over conventional weapons. They do not require highly accurate targeting systems. Their disadvantage is that the "kill radius" can affect both friendly and enemy satellites.

Nuclear weapons in space are strictly prohibited by international treaty. The United States did have a nuclear warhead ASAT capability from approximately 1963 to 1975. Western observers believe that the U.S.S.R. has maintained a similar capability since the early 1960's.

Laser and Particle Beams

High-energy directed-weapons, such as lasers and particle-beams, require accurate targeting mechanisms. Research is being conducted in the U.S. and Soviet Union.

The U.S.S.R. is believed to have an operational ground-based laser ASAT system. The United States has conducted several airborne tests of a laser system. Some experts believe that technology for an ASAT system will have to wait until some date in the distant future.

The U.S. Department of Defense states: "Lasers can be used to 'blind' the sensors on a satellite, or if sufficient power is available, to destroy [illegible] satellite through heating.

"Particle-beams (charged or neutral atomic particles—electrons, protons, or neutrons) could destroy a satellite through heating or by disrupting its electronics.

"A major advantage of directed-energy weapons is that their destructive energy travels at the speed of light, denying the target sufficient time for any possible evasive maneuvers. Also, several targets could be engaged consecutively in very short periods of time.

"The major disadvantage is that the systems require great amounts of energy and large associated structures, making them difficult and expensive to construct in space and vulnerable to attack.

"The alternative, basing laser systems on Earth and aiming them up into space, presents difficulties because the Earth's atmosphere tends to disperse the beam, and only a small fraction of energy reaches the target. For particle beam weapons, Earth-basing would present the possibility of the path being deflected by the Earth's magnetic lines."

Tests

Atmospheric testing of laser weapons has occurred. Supporters maintain that space-based ASAT lasers could become available this decade. Critics argue it will take 20-30 years. Particle-beam technology is further behind laser weapon research. Directed-energy weapons could be used for ballistic missile defense.

Ground-based Systems

During the 1960's, ground-based ASAT systems were studied by the United States. An operational system was developed by the U.S. Army using NIKE-ZEUS missiles at Kwajalein Atoll in the Pacific. Tests were conducted from May 1963 until deactivated in 1964. The Air Force tested a system using THOR missiles on Johnston Island, also in the Pacific. Beginning in May 1964, it remained operational until 1975.

Soviet Union

The Soviet Union appears to have several different ASAT systems. A ground-based co-orbital system is "operational" according to the Defense Department. Rumors of a

direct-ascent nuclear ASAT or ground-based laser have not been confirmed. Soviet Premier Nikita Khruschev told American reporters on July 16, 1962, that the Soviet Union could "hit a fly in outer space." This was interpreted to indicate that the Soviets had an ASAT capability using nuclear warheads on GALOSH missiles at the Shagan facility and around Moscow. Such an ASAT system remains unconfirmed.

Soviet Co-orbital

The most favored Soviet ASAT system appears to be a ground-based, explosive ASAT device. An interceptor would be launched by a SCARP launch vehicle (similar to the SS-9).

It is believed that the Soviet Union has conducted some 20 tests of their ASAT system. Exactly how successful the Soviets have been is said to be difficult to determine.

Air-based Systems

The Defense Department is developing a Miniature Homing Vehicle (MHV) which could be launched from a two-stage rocket or carried by an F-15 aircraft. Using sensors, the MHV would locate, track and destroy the target satellite by impact force.

Range of the MHV-ASAT is classified. But Soviet reconnaissance, weather and navigation satellites are believed to be within range. The Soviet Salyut space station and manned and unmanned-resupply vehicles are also within range.

Pentagon experts note that U.S. ASAT systems are more flexible than those being developed by the Soviet Union, since F-15's could be based anywhere in the world. ASAT-carrying F-15's based in the southern hemisphere would make Soviet early-warning and communications satellites vulnerable. Prime targets for U.S. ASAT systems reportedly might include Soviet nuclear reactor-powered ocean reconnaissance satellites. Dr. Robert Cooper, director of the Defense Advanced Research Projects Agency (DARPA) stated in April 1982 that 15 "aircraft would be equipped for the ASAT role." A year later, he stated that six "captive tests of the ASAT had been successfully completed."

Test Launch

A successful launch of an air-based ASAT launched from an F-15 took place in January 1984.

On January 27, 1983, the General Accounting Office (GAO) issued a report on the U.S. ASAT program. GAO said the air-launched ASAT system was selected as a quick and cheap form of ASAT capability, but it has become "a more complex and expensive task than originally envisioned, potentially costing in the tens of billions of dollars." GAO recommended Congress review the program and consider possible alternatives before the vehicle enters production.

Conventional Space-based Systems

From 1960 to 1962, the United States had a program to develop a satellite capable of rendezvous with enemy satellites in earth-orbit. Called SAINT, this project never reached the flight-testing stage.

Little is known about Soviet programs in this area.

Space Shuttle as ASAT

The U.S.S.R. has told the United States it considers the Space Shuttle an ASAT-related vehicle, based on the fact that the shuttle can maneuver close to satellites. The shuttle's Remote Manipulator System (RMS) can be used both to deploy and retrieve satellites in orbit. The Soviets contend the RMS could attach destructive devices to satellites.

The Space Shuttle will test systems having an ASAT application. It could also carry components of space-based weapons into orbit. The National Aeronautics and Space Administration denies that the Space Shuttle is a weapon.

The United States has expressed concern about potential Soviet attack on the Space Shuttle. The Defense Department has raised the possibility of equipping the shuttle with defense laser systems. The Soviets have countered that this would positively make the Space Shuttle an offensive weapon.

Space-based Ballistic Missile Defense

Similar technologies could also be applied to destroy ballistic missiles enroute to their targets. Intercontinental Ballistic Missiles (ICBMs) and Submarine-Launched Ballistic Missiles (SLBMs) must "arc" through space to reach their targets. A space-based defense system could be developed to destroy these missiles before separation of individual warheads.

A group called High Frontier prepared such a plan in 1982, proposing a Global Ballistic Missile Defense System. It recommended placing 432 satellites into Earth-orbit, each armed with 40-50 Miniature Homing Vehicles based on the design for the F-15 ASAT system. The group stated that a space-based BMD system could be established with existing technology.

Laser or particle beams could also be used for space-based ballistic missile defense, according to some analysts.

Particle-beams and Lasers

Currently, the United States is developing the necessary technology for a space-based laser weapons system. This system could have ASAT applications.

The U.S. Air Force has tested an "airborne gas dynamic laser" for use against tactical missiles. As noted by Air Force Secretary Hans Mark in 1981, "These efforts will lead naturally to the solution of problems that will be faced when we are ready to put high-energy lasers in space."

The Defense Advanced Research Projects Agency (DARPA) has been developing a space-based laser technology program "which involves three technologies and is referred to as the 'space-laser triad.' The first technology, for acquisition, pointing and tracking of the target, is code-named TALON GOLD; it will be tested in 1985 aboard the Space Shuttle as part of the Air Force Space Test Program. The TALON GOLD experiment will test a low-power laser against both high-altitude aircraft and space targets. The second technology area, high efficiency infrared chemical lasers, is being developed under the name PROJECT ALPHA; it is a ground-test program to establish the feasibility of a laser suitable for use in space. Chemical lasers are considered better than gas dynamic lasers for space purposes because they are smaller, require low temperatures and a vacuum (the conditions in space), for operation and the toxic wastes would not present a disposal problem. ALPHA was originally designed to produce 5 megawatts of power, but recent developments may enable doubling that power level. New advances in short wavelength lasers may show that these would be preferable to chemical long-wavelength lasers. The third technology, mirror and beam control optics, is being studied under the name LODE (Large Optics Demonstration Experiment). It is designed to establish the feasibility of large aperture beam control in space." Funding for DARPA's high-energy laser program was $129 million in FY83. The FY84 request is $172.6 million.

ASAT Funding

The individual armed services have also developed their own high-energy laser programs. Together with DARPA, they have spent nearly $2 billion on research. Particle-beam research in the United States began in 1958. Then called SEESAW, it was terminated in 1972 by DARPA. In 1974, the Navy Department established CHAIR HERITAGE, its own particle-beam program. It was later transferred to DARPA in 1979.

A little over a year later, in 1980, the Army's particle-beam program, called WHITE HORSE, also became a part of DARPA.

During consideration of the FY83 request, debate emerged over whether to continue existing research programs for developing chemical lasers or proceed with short wavelength laser technology. The FY83 DOD funding bill added $20 million for short wavelength laser technology, as opposed to high-energy laser research in general. It funded $173 million for DARPA and $36 million for the Air Force.

A new Strategic Laser Systems Technology Program was created by the Department of Defense Appropriations Bill. $28 million was provided for space-based laser research. DARPA's Strategic Technology Program of $280.5 million and the Advanced Radiation Technology Program of $52.53 million also received funding.

Estimates on when the United States might be able to launch an operational space-based laser range from 6 to 30 years.

Soviet Laser and Particle-beam Research

For years, experts have speculated that the Soviet Union is developing space-based particle-beam and laser weapons. During congressional hearings in March 1982 portions of a Defense Department classified report on Soviet laser efforts were inadvertently read into the record. That report suggested that the U.S.S.R. would be capable of launching a space-based laser into earth orbit in 1983. Dr. Richard DeLauer, Undersecretary for Research and Engineering, later stated that 1983 was "the bottom range of possibilities" which the Defense Department considered likely. Dr. DeLauer stated that he believed "the Soviets have about a five-year lead in space-based laser technology over the United States, and that since we could place such a weapon in orbit in possibly ten years, then the Soviets may do so five years from now."

He said, "Over the past ten years, the Soviets are also estimated to have taken the lead in the development of directed energy weapons such as high-power lasers and possibly radio frequency devices. They have devoted substantial resources in these areas, and the fact that they are developing very high-power microwave generation also gives rise to suspicions of possible weapon intent. For example, their high energy laser program is three-to-five times that of the U.S. level of effort, and tailored to development of specific laser weapon systems (as opposed to the U.S. work which is largely exploratory). Available information suggests that the Soviet weapon effort is by far the world's largest, and possibly could lead to a demonstrated capability in a wide variety of ground, ship and aerospace application during the latter half of this decade.

"Finally, Soviet spacecraft perform more than a dozen specific military functions, several of which are directly associated with weapon systems. In fact, we believe their space station program engages in military activities and may be the forerunner of a weapons platform. In sum, based on the evidence available to us, it is clear that the Soviets have a massive military space program."

Action in the Current Congress

CONGRESSIONAL INTEREST IN SPACE WEAPONS has risen considerably in the current Congress. One resolution has been reported from committee in the Senate and two are pending in the House. Both call for a resumption of the ASAT limitation talks with the Soviets. One House and one Senate resolution would promote international cooperation in space as an alternative to a space arms race. Conversely, one Senate resolution, one Senate bill and one House bill would accelerate U.S. space weapons programs. Five sets of hearings have been held specifically on this topic. In addition, two amendments were debated on the House floor and two on the Senate floor during consideration of the FY84 DOD Authorization Bill relating to space weapons. Language was added to DOD appropriations bills as well.

Opposition to Space Weapons

Two resolutions in the House are H.J.Res. 87, introduced by Representative Robert W. Kastenmeier, Wisc., Dem., on January 25, 1983; and H.J.Res. 120, introduced by Representative Moakley and 76 co-sponsors on February 2, 1983. The two resolutions are very similar. They call on the President to resume talks with the Soviet Union aimed at banning all weapons from space. The Moakley resolution directs the President to request the United Nations to initiate negotiations aimed at expanding Article IV of the 1967 Outer Space Treaty to include such a ban. Hearings were held by the House Foreign Affairs Committee on November 10, 1983.

In the Senate, S.J.Res. 28 was introduced by Senator Paul E. Tsongas, Mass., Dem., and two co-sponsors on February 3, identical to Rep. Moakley's resolution. On February 2, Senator Pressler and 6 co-sponsors introduced S.Res. 43 calling for negotiations to ban antisatellite weapons as a first step towards banning all weapons from space. Following hearings on April 14 and May 18, 1983, Senators Pressler and Tsongas and others introduced a compromise resolution. S.J.Res. 129 was favorably reported by the Senate Foreign Relations Committee on November 18, 1983.

Senator Matsunaga introduced S.Con.Res. 16 on March 10, 1983. This expressed the sense of the Senate that the President renew the space cooperation agreement with the Soviet Union and explore opportunities for cooperation in space as an alternative to an arms race in space. A similar resolution, H.Con.Res. 140, was introduced by Representative Mel Levine, Calif., Dem., and 6 co-sponsors on June 30, 1983.

Support for Space Weapons

On March 24, 1983, Senators Malcolm Wallop, Wyo., Rep., and Paul Laxalt, Nev., Rep., introduced S.Res. 100, calling for the President to request funding to establish a space-based ballistic missile defense system as soon as possible. The resolution was referred to the Armed Services Committee.

On May 19, 1983, Representative Ken Kramer, Colo., Rep., and 11 co-sponsors introduced H.R. 3073, the People Protection Act. The bill would establish a new agency for accelerating the development of directed-energy technology. It was referred jointly to the Committee on Armed Services, Foreign Affairs, and Science and Technology. Hearings were held by the House Armed Services Committee on November 10. Senator William L. Armstrong, Colo., Rep., introduced S. 2021, an identical bill on October 28.

In addition to the two House hearings noted above, the Senate Foreign Relations Committee held hearings on space weapons and on the President's March 23 speech on April 14 and May 19. The Senate Armed Services Committee held one day of hearings on May 2.

Floor Debate

During House consideration of the FY 84 DOD Authorization Bill, H.R. 2969, Representative George E. Brown, Jr., Calif., Dem., tried to deny procurement funding of $19.4 million for the U.S. ASAT system. Research and development funding would not have been affected. The amendment was debated on May 26 and June 14. It was defeated by a vote of 243-177. On July 21, Representative John F. Seiberling, Ohio, Dem., introduced an amendment to prohibit flight tests of the U.S. ASAT until authorized by Congress. The amendment was defeated 275-142.

In the Senate, on July 18 an amendment introduced by Senator Tsongas was adopted by a vote of 91-0. This provided that no funding be used to test any explosive or inert ASAT against objects in space unless the President certified to Congress that (1) "the U.S. is endeavoring in good faith to negotiate a treaty with the Soviet Union for a mutual and

PRO

Are Administration Initiatives Sound

by Hon. John W. Warner
United States Senator, Virginia, Republican

From an address delivered on the floor of the U.S. Senate on March 24, 1983. Sen. Warner is a member of Senate Committees on Armed Services, Energy & Natural Resources, and Rules & Administration.

PRESIDENT REAGAN ANNOUNCED a comprehensive and intensive effort to define a long-term research and development program to begin to achieve our ultimate goal of eliminating the threat posed by strategic nuclear missiles. This program would capitalize on our technological capacity to develop means by which we could intercept and destroy strategic ballistic missiles before they reached our own soil or that of our allies.

"The potential contribution of directed energy weapons is significant."

The Senate, over the past 3 years, has been taking increased interest in this area. The initiatives of the President will be received and studied with great interest.

The potential contribution of directed energy weapons is significant. For example, they could deny the use of space for collecting and distributing crisis management and targeting information while protecting our space assets that warn against a surprise attack; engage and defeat limited nuclear strikes using ballistic missiles by engaging such missiles in the vulnerable boost phase; provide response options that neutralize or disrupt enemy targets in a measured, selective manner without breaking the nuclear threshold; selectively thin out the attacking missiles and aircraft and disrupt any attempt at a disarming first strike; aid U.S. strategic force retaliatory strikes by suppressing air defenses; and continually attrit reserve strategic forces in a nuclear war and deny targeting information essential to the effective use of such forces.

Directed energy weapons might be used as a stand-alone defense, or more likely, as part of a defense-in-depth concept. Second, considerable research and development is underway on laser and particle beam-related systems with potential for defensive weaponry.

"Laser beams, particularly the chemical laser, will likely be the first deployable beam weapons developed."

Laser beams, particularly the chemical laser, will likely be the first deployable beam weapons developed. A laser is a beam of very intense, single wavelength electromagnetic waves, either of light or high energy X-rays. Such a weapon can be focused very precisely because either the light or X-ray wavelengths all have the same frequency and phase. The five different types of lasers, which can be applied to fusion energy as well as beam weapons, are all being researched at U.S. laboratories.

The chemical laser, which could be developed for military deployment, uses a gaseous medium in which a chemical reaction is induced. The product of the reaction emits laser light.

The gas laser, a burning gas such as a hydrogen and flourine mixture, is suddenly compressed, and the energy distribution that results from the compression is then stimulated to emit single-frequency light waves at very high energy.

An electron discharge laser uses replaceable energy from an electron beam to create the source of laser light. Such a laser would be very efficient for use in space

Space Weapons National Policy?

CON

by Hon. Larry Pressler
United States Senator, South Dakota, Republican

From addresses delivered on the floor of the U.S. Senate on February 17 and April 7, 1983. Sen. Pressler's committee assignments include chairmanship of the Subcommittee on Arms Control of the Senate Committee on Foreign Relations.

WE, FAR MORE THAN THE SOVIETS, would be compromised by a space weapons race because we must, out of necessity, rely upon space-based systems for conducting many functions. The Soviets do have alternatives to space-based systems—alternatives that we do not possess. This is both a product of our open society and our particular geographic situation.

"We, far more than the Soviets, would be compromised by a space weapons race..."

I would like to address another aspect of this issue, and that is the very high cost of a space weapons race and its likely implications for the American taxpayer, who is already heavily burdened by the high cost of keeping America safe. Adding a space dimension to United States and Soviet weaponry is likely to add significantly to this burden. Moreover, we already face major deficiencies in the current constellation of air, land, and sea forces. Aircraft reportedly lack spare parts; we have insufficient ammunition for sustaining any potential lengthy conventional war in Europe; we do not have enough chemical warfare clothing for troops; the list is very long in this area. Given a new burden in the area of space weaponry, we cannot hope to make good on these deficiencies. Indeed, we are likely to exacerbate the problems and we will likely be spreading ourselves even more thinly.

It is for this reason that I support immediate resumption of ASAT talks. If we cannot ban space weaponry at this early stage in the competition, then I believe that it will be increasingly difficult, if not impossible, to avoid ever higher expenditures on space weaponry. We will be like the habitual gambler who has to continually double his bet to stay in the game. Once we enter this game, which is already very expensive even though it is still on the ground, it will be ever more difficult to find a way out.

"..let us consider the U.S. ASAT weapon ... With this money, we could do better things in defense and... serving American taxpayers."

First, let us consider the U.S. ASAT weapon which is soon to be tested and deployed. The current price tag for that system is $3.6 billion. This is already a sevenfold increase over the advertised cost when it was initiated several years ago. With this money, we could do better things in defense and in the area of serving American taxpayers.

That program has not received the close congressional scrutiny it deserves. We have here a system that, in dollar value alone, approaches the MX missile's advertised price tag. I believe that before we move toward testing and deployment of this ASAT system, which will join the F-15 aircraft to a rocket and a satellite interceptor, we must give it the same close examination that has attended the MX system. If we are to have any examination of the strategic implications of this ASAT, as well as its budgetary consequences, the Senate must act quickly, for once the system is tested our ability to influence this program will be very limited.

Beyond ASAT's, there are many additional concepts floating around the defense

(Continued on page 77)

PRO **WARNER,** cont. from page 74

because its energy source is electricity, not an exhaustible chemical fuel.

Two other types of lasers, X-ray lasers and free-electron lasers, yet to be perfected technologically, have greater advantages of energy density and flexibility than those listed above. The X-ray laser has promise for long-range ballistic missile defense, based in space. The X-ray laser, which is just a single pulse, is by far the most energy-dense, delivering thousands of times more energy per pulse than conventional lasers. In addition, the target absorbs the X-rays very efficiently, making this weapon capable of very efficient destruction of missiles.

Particle beams also deliver energy in a highly controlled pulse traveling at near the speed of light. But instead of a pulse of intense electro-magnetic radiation, the particle beam consists of subatomic particles, electrons or protons, neutral atoms, usually hydrogen, or usually magnetized macroscopic particles accelerated to high speeds. A particle beam destroys its target, the triggering mechanism, by creating a very intense shock wave within the mechanism, like a very small, but extremely heavy and powerful hammer striking down on the target.

"The X-ray laser has promise for long-range ballistic missile defense, based in space."

Electron beams can be generated in the range of millions of volts. Scientists researching the electron beam for military or civilian energy use have discovered that the electron beam becomes a complex structure of electrons and a magnetic field. Such structured beams are capable of carrying higher currents and more energy for much longer distances at much greater levels of power output.

Proton beams, which have been researched intensively for the past 30 years, use an electron beam as a seed and then are accelerated in their own right. As protons are 2,000 times heavier than electrons, a proton beam of the same velocity has 2,000 times the energy of an electron beam.

Neutral particles eliminate many of the problems of charged-particle beams, which can degrade both the efficiency and controllability of the beam. U.S. researchers hope to produce a beam of protons at an energy of 2.5 million electron volts, capable of traveling at 99 percent of the speed of light.

Control and targeting of a macroscopic particle beam would be more difficult, but the unparalleled power density of the beam—due to the large mass of the particles—gives it considerable potential as a beam weapon.

"In addition, nonnuclear ballistic missile defense systems are being researched by the Army."

The Department of Defense is pursuing development efforts related to space-based, air-borne, and ground-based laser systems for antisatellite, antiaircraft and possibly antiballistic missile defense missions. Serious work is also being performed on particle beam weapon systems.

In addition, nonnuclear ballistic missile defense systems are being researched by the Army. Such systems could provide a capable point-defense of national assets in the 1990s.

The private sector has also offered proposals—largely drawing upon the technologies under development by the Department of Defense—intended to give the United States an enhanced strategic defense capability. One such proposal, called "High Frontier," would involve three components.

The first system would be a ground-based defense of missile silos that would consist of rapid-fire guns able to launch a cloud of projectiles and destroy incoming warheads before they reach their target.

The second system would be a global ballistic missile defense that would consist of 432 satellites, all hardened to minimize the effect of nuclear explosions outside

(Continued on page 78)

CON **PRESSLER,** cont. from page 75

community calling for lasers and particle beam weapons that could be based on Earth and aimed at satellites in orbit or, alternatively, based in space and targeted at other space systems. The cost of such systems is difficult to predict, for the simple reason that they require several as yet unattained major scientific and technological breakthroughs. However, we can safely say that the cost will greatly exceed the "tens of billions of dollars" that the GAO estimates for the current U.S. ASAT effort which is based upon off-the-shelf technology.

Beyond antisatellite platforms, there are concepts that call for space-based military fortresses which would attack several space systems at once or would provide for an anti-ballistic missile defense in the skies. The most prominent of these concepts to date is the High Frontier concept. High Frontier would be based, we are told, on current technology that would use conventional weapons to attack ballistic missiles in their boost phase. Let me note that this concept is prohibited by the 1972 ABM Treaty to which we and the Soviets are bound. At a minimum, High Frontier would require a renegotiation of that accord and at a maximum we might have to give up what many regard as the most useful arms control accord to date to deploy the High Frontier.

"Should we believe that it is in our security and budgetary interests to accept such a costly new arms race?"

But there is another important question that is raised by High Frontier. Can we afford it? While the proponents claim that it would cost only $40 billion—and that is an astronomical amount of taxpayer money—other estimates, including one offered recently by the Armed Forces Journal, put the price tag at between $200 and $300 billion. That amount rivals the annual U.S. defense budgets for the mid-1980's. Once we begin to talk about other more exotic concepts, that price tag will continue to increase.

Should we believe that it is in our security and budgetary interests to accept such a costly new arms race? Once it begins, it may be impossible to avoid these even more sophisticated and ever more costly weapons in space. Or should we examine the situation closely to consider the possibility that arms control may provide an alternative to such a space weapons race? I believe that we have no alternative to first giving arms control a try.

I agree with the President that the United States has fallen behind in some areas in the development of our military forces. The problem we face is as much a problem of sustainability—that is, the provision of spare parts, sufficient ammunition, pilot training, and such—as it is an issue of strategic forces modernization.

"... the proposed laser BMD would lead to both an increased tax burden and reduced spending in other military areas."

I commend the President for keeping the U.S. laser program option open. Concerning the ground and space deployment alternatives, in the view of many specialists these weapons will be space based. There may be too many problems to overcome in operating a laser through Earth's atmosphere. Laser energy is dispersed and laser beams bend under atmospheric conditions. Moreover, if we are to provide our allies with the protection of a laser-ballistic missile defense (BMD) system, space basing seems the better approach.

Let me note the more obvious problems with a space-based BMD system. At the top of the list are the budgetary and strategic implications of such a weapons program.

Costs would have to come from somewhere and, as I see it, the proposed laser BMD would lead to both an increased tax burden and reduced spending in other military areas. We would not be in a position to modernize and correct existing

(Continued on page 79)

PRO WARNER, cont. from page 76

the Earth's atmosphere. These satellites would be constantly orbiting at about 300 miles altitude, each armed with 40 to 50 intercept devices similar to the air-to-air missiles now carried by U.S. fighter aircraft.

The third system would be a second generation global ballistic missile defense whose specific configuration would depend upon the rate of technological advance. It might simply be an upgrading of GBMD-I, or, depending on the solution to problems of directed-energy beam weaponry, could be an entirely new system.

"..the President is correct in his recognition of the potential offered by American technology for our national security."

Uncertainties exist about the cost, technical feasibility and arms control implications of each of these approaches.

Just as important as the technical capabilities of these approaches are the provisions and goals of existing and future arms control treaties. I can not emphasize too strongly the need to coordinate the technical development of these weapons within the framework of the existing arms control agreements and the future agreements the world hopes and prays for.

I believe that the President is correct in his recognition of the potential offered by American technology for our national security. His assessment that, "years, probably decades, of effort on many fronts is required" is also correct. I believe that his call for increased attention to our technological capability will lend an impetus that may provide positive dividends. The precaution and responsibility that we have is not to raise hopes and expectations too early.

by Hon. Howell Heflin

United States Senator, Alabama, Democrat

From an address delivered on the floor of the U.S. Senate on April 27, 1983. Sen. Heflin in a member of Senate Committees on Agriculture, Nutrition & Forestry; Commerce, Science & Transportation; and the Judiciary; as well as the Select Committee on Ethics.

I SINCERELY BELIEVE THAT AN OBJECTIVE EXAMINATION of President Reagan's recent call for the development of strategic defense systems will disclose that this is a concept whose time has come.

Once past the emotional reactions of those who are tied to the strategic doctrines of the past, this new approach may, indeed, lead to an ultimate reduction in offensive missiles on both sides.

"For too long we have relied on strategic policy based on the threat of retaliation rather than a commitment to self-defense."

For too long we have relied on strategic policy based on the threat of retaliation rather than a commitment to self-defense. I have wondered ever since the signing of the ABM treaty in 1972, what could be more stabilizing than the ability to defend one's homeland against nuclear attack?

Yet, many of those who are most vocal through the media continue to insist that defense would touch off a new arms race by raising fears that one side was preparing to attack and then defend itself against retaliatory attack. Defense, in fact, is not provocative—it is the opposite. If each side neutralizes the other's offensive capability, the threat of aggression must be reduced. The U.S. history discloses proudly that ours is not an aggressor nation. But several times, we have been caught, with almost

(Continued on page 80)

CON **PRESSLER,** cont. from page 77

deficiencies in our current conventional and strategic forces. We are, therefore, likely to be spending more and be doing more militarily, but we are also likely to be doing many things badly rather than a few things well.

Strategically, there would be little to gain from such a space-based BMD system. As the President rightly noted, should we end up adding lasers to the U.S. weapons posture it could be "viewed as fostering an aggressive policy." I might add, this policy could be highly destabilizing. One possible course of action would require that we combine the strategy of building a BMD system together with negotiating very significant arms reductions in strategic forces. There is irony in this situation. If we can reduce our strategic forces to a point where a BMD system would no longer appear "aggressive," then we would also greatly reduce the need for a laser BMD network.

"Strategically, there would be little to gain from such a space-based BMD system."

Let me note again that the actual deployment of a space-based ballistic missile defense is expressly prohibited under Article IV of the 1972 ABM Treaty. This prohibition extends to development, testing and deployment of such a system. The ABM Treaty is perhaps the single most important achievement in arms control to date. It has prevented a costly arms race in defense systems, and it has saved taxpayers a great deal of money. The United States and the Soviet Union have reaffirmed their commitment to this accord in Geneva. Nothing that I have seen to date would seem to warrant abandoning this cost-saving and strategically stabilizing agreement.

For over 2 years now I have urged that the United States and the Soviet Union return to the negotiating table to ban antisatellite weapons as a first step toward banning all weapons in space. If an arms race is to be avoided, we must begin to negotiate soon, since the Soviets presently possess and the United States will soon test and deploy an antisatellite weapon.

As I have frequently noted, the best time to stop an arms race is before it begins. As is evident from this most recent development on BMD, it will become increasingly difficult to reverse the momentum of a space arms competition once it gets under way. We should add to this the verification problems that will emerge that could make space arms control difficult, if not impossible.

"... the best time to stop an arms race is before it begins."

It should be noted that space systems are highly vulnerable to attack and, though we can develop countermeasures to protect our satellites, it can be stated with some degree of certainty that the Soviets will be working to defeat each package of countermeasures with a program of counter-countermeasures. There is nothing to be gained from a space arms race, but ever-increasing costs and ever-increasing instability.

We should not assume that by adopting laser technology we will steal a march on the Soviets. Moscow is said to be 5 or more years ahead of the United States in the development of directed-energy weapons. The Soviets currently spend three to five times as much on military space activities. It is in our interest to avoid an arms race in space with Moscow rather than seek to join them in such a competition.

I would urge Senators to consider Senate Resolution 43 which I have offered with eight cosponsors. This resolution calls on the President to immediately prepare a proposal and invite the Soviet Union to negotiate a verifiable ban on antisatellite weapons as a first step toward prohibiting all space-based and space-directed weaponry.

(Continued on page 81)

PRO **HEFLIN**, cont. from page 78

tragic results, with our guard down.

Still, there are numerous critics who suggest that ballistic missile defense (BMD) is destabilizing. Their arguments should be challenged not only on first principles, but on the grounds that major reductions in offensive weapons are made more feasible if such weapons are protected by BMD.

It is not simply how many strategic weapons are allowed on each side, but how survivable those weapons are. Therefore, we must see to it that a strategic defensive policy that is basically conducive to arms control is not made to appear as the reverse.

I am convinced that it was our technical superiority in strategic areas which induced the Soviets to agree to the ABM treaty, as well as SALT I. When the ABM treaty was negotiated it was assumed major reductions in offensive ballistic missile forces would be shortly forthcoming. Instead, the Soviets stepped up their strategic programs on all fronts and, today, our land-based ICBM force stands vulnerable to a first strike. Vulnerability, I submit, is the most provocative and destabilizing condition of all, encouraging, at the minimum, international adventures backed by the threat of a first strike.

"It is not simply how many strategic weapons are allowed on each side, but how survivable those weapons are."

The ABM Treaty permits limited deployment by both sides, and the Soviets have a system deployed around Moscow. However, Congress decided in 1976 to phase out our deployed site at Grand Forks, S. Dak. Meanwhile, the Soviets have continued with a system-level program, at expenditures three times greater than ours, which we assume could be rapidly deployed in the future. The United States has pursued a modest R&D ballistic missile defense (BMD) program since the early 1970's, progressively developing means to defend our ground-based ICBM force and developing technologies which have provided remarkable advances for future defensive options.

I agree with President Reagan that we need to step up the pace of R&D on advanced long-range BMD concepts which will fully challenge our Nation's creative scientific capabilities for success and breakthroughs as well as our political willingness to seek visionary solutions. In this connection, I was one of the first Members of this body to speak out on the potential use of directed energy technologies, such as high-energy lasers, for future defensive weapons.

"In the future, we should be able to use ground-based or space-based, high energy lasers to destroy ballistic missile targets..."

In the future, we should be able to use ground-based or space-based, high energy lasers to destroy ballistic missile targets, as well as other offensive targets. I have felt for some time that we need to accelerate our efforts in the development of this technology. However, one of my primary concerns has been the fragmentation and lack of coordination among the various Government agencies of the current research and development in the area of directed energy.

This concern was amplified as a result of hearings that I chaired in late 1979. The purpose of these hearings was to provide a broader review of the highly diverse, important, and rapidly developing laser technology. From these hearings, I determined that we did not have the proper environment to focus this technology. Therefore, in the last Congress, I introduced legislation calling for a Laser/Particle Beam Institute to provide a long-range program in this area and serve as a coordinating and managing body for those Government agencies involved in laser/particle beam research and development.

While the President's March 23, 1983, announcement properly emphasized the

(Continued on page 82)

Given the risks and costs of a space arms race, we must give arms control a serious try. Before we embark on this deadly competition, the American people must be convinced that we are engaged in this race because of Soviet insincerity, rather than for lack of serious negotiating efforts on our part. Americans have the right to demand this for they will pay the cost of space weapons and they will suffer the consequences that could follow from a deterioration of global security.

"Given the risks and costs of a space arms race, we must give arms control a serious try."

by Hon. Paul E. Tsongas

United States Senator, Massachusetts, Democrat

From a statement addressed to the Senate Committee on Foreign Relations in the course of hearings on May 18, 1983, to consider pending resolutions calling for a ban on space weaponry. Sen. Tsongas is a member of Senate committees on Energy & Natural Resources, Foreign Relations, and Select Small Business.

THE SUBJECT OF SPACE-BASED WEAPONS is one of the most crucial military and political issues facing the world today.

I would like to comment first about antiballistic missile systems. In my view the Administration's recent and highly publicized emphasis on ABM weapons is based on false strategic premises, and steers the arms control debate in a direction that can only benefit the Soviet Union. I would like to make three points to explain my thinking.

First of all, it is clear that there is no such thing as a perfect safety net to defend against Soviet nuclear weapons. There is no such thing now, nor do the most optimistic technological projections suggest that there ever will be. Only a few nuclear weapons can cause fearsome damage. No safety net can guarantee that at least a few nuclear weapons—carried by ballistic missiles, bombers or some other means—could not slip through our defenses. There is, unfortunately, only one way this country can deter such an attack: by maintaining the ability to inflict unacceptable damage on any potential aggressor.

"... there is no such thing as a perfect safety net to defend against Soviet nuclear weapons."

I wish it were otherwise, but that is the reality.

Second, ABM weapons are not defensive; they are offensive. They only serve to protect the aggressor nation from retaliation. The 1972 ABM Treaty was the result of the American ability to convince the Soviets of this reality. The reason is simple: an ABM system can be countered by launching more missiles than it can handle. But to do this with the missiles remaining after a massive, counter-force first strike would be extremely difficult. That is, it is possible to defeat an ABM system as part of a first strike; it may be impossible to do so in a retaliatory strike. Thus, ABM systems are part of a first strike capability, and provide less deterrence than the ability to retaliate in kind.

Third, all our ABM talk and our lack of action on arms control are fueling the Soviet propaganda machine.

Meanwhile, the popular movement for an end to the arms race grows here and in Europe. This propaganda war for the hearts and minds of the world is not going in our favor. While President Reagan hints at abrogating the ABM Treaty, Yuri

(Continued on page 83)

PRO HEFLIN, cont. from page 80

more advanced, long-term BMD concepts, I would encourage him to seriously consider an evolutionary approach that also would include more mature, nearer term BMD concepts.

I have followed with great interest the progress in Army BMD systems and technology development centered at Huntsville, Ala. This program has made dramatic strides in recent years over a broad spectrum of systems.

"These technology successes provide vast encouragement to the hopes for a successful strategic defense in the future..."

As early as the 1960's, BMD demonstrated essential strategic defensive systems technologies, including phased array radars and Sprint-class interceptors. By the 1970's, the program technologies were developed to enable defense against sophisticated missiles in the terminal stages of attack through the use of complex data processing, and discriminating technologies, and quick-response interceptors. The program evolved in the 1970's with the development of on-board data processing and long-wave infrared sensors for early identification of targets outside the atmosphere. Today, BMD is demonstrating advanced sensors and data processing and smart missiles capable of intercepting incoming missiles with nonnuclear warheads. Programs also are already underway in the nontraditional technology areas of directed energy weapons.

These technology successes provide vast encouragement to the hopes for a successful strategic defense in the future and can be demonstrated, with the option for deployment, on an evolutionary basis while futuristic space-based systems concepts are maturing. Skeptics have dismissed the long-range portion of this thinking as a "Star Wars" fantasy, but I believe history will prove them to be wrong.

Secretary Caspar W. Weinberger recently noted:

"Perhaps one reason for the skepticism with which some have greeted this initiative is due to misunderstanding. Many would have you believe that we seek to develop a single system which can intercept and defend flawlessly against all missiles and all attacks. We know there is no such 'magic bullet'. What we are trying to develop first is a defense network—a series of systems, not necessarily based on the same technology or physical principles—which taken together will provide a reliable defense against nuclear ballistic missiles.

"Skeptics have dismissed the long-range portion of this thinking as a 'Star Wars' fantasy, but I believe history will prove them to be wrong."

"The concept we will need to perfect is not dissimilar to the one we now employ to defend our fleet against tactical missile attack. The layered fleet defense system consists of F-14 fighters and Phoenix Missiles at long ranges, the Aegis Cruiser at medium range, and close-in weapons systems. All are under control of computers which keep track of dozens of incoming missiles, and direct interceptors to destroy them. The ballistic missile defenses we seek to build must do these functions also, not against dozens of targets, but against thousands and at vastly greater ranges."

Secretary Weinberger was referring to a defense network, which I believe to be consistent with BMD's layered defense concept, where defense is possible in various regimes of an attacking missile's trajectory.

My interest in also considering more mature BMD concepts is based on several compelling factors that are consistent with the President's policy initiative. They can be fielded earlier and they can be securely based on our own soil. They would pose no threat for any use other than purely defensive objectives, and they would effectively complement any advanced systems that may be deployed later.

I am convinced that we should carefully and objectively evaluate the President's

(Continued on page 84)

CON TSONGAS, cont. from page 81

Andropov is offering to negotiate a complete ban on weapons in space. As public opinion shifts in Western Europe and elsewhere, the Soviets may conclude that they can obtain U.S. arms concessions without negotiating. We may end up with either no agreements or ones overly favorable to the Soviet Union. We only worsen our position by leaving the high ground to the Kremlin.

If we want to give the Soviets the greatest incentive to stick to the ABM Treaty, we must continue research work on potential ABM technologies. Our research will keep the Soviets honest because they would know that should they develop and deploy an ABM system in violation of the treaty we could match them tit for tat. But we should not make it a top national priority to develop an ABM system, particularly as this may involve violating an arms control accord. The 1972 ABM Treaty expressly forbids development, testing and deployment of ABM systems based in space. Thus, even to test an ABM system is to imperil the arms control efforts that ought to be our highest priority.

"If the United States tests its anti-satellite weapon, as is planned, we will enter a new and more dangerous phase in the arms race."

A second issue concerns anti-satellite weapons. The issue here is no less acute. We are approaching a watershed. If the United States tests its anti-satellite weapon, as is planned, we will enter a new and more dangerous phase in the arms race. The ASAT system we are about to test may not be amenable to verification. The U.S. ASAT consists of a small homing missile launched from a high-flying F-15. An F-15 carrying such a weapon would be undistinguishable from any other F-15. The missile itself kills by directly ascending up to the satellite and colliding with it, and the overall system should be markedly superior to current Soviet systems. To test this system could seriously reduce chances for obtaining a verifiable restriction on anti-satellite weapons. On the other hand, unilateral action on our part can lead to disaster. The Soviets have been testing their crude, co-orbital ASAT since the late 1960's. While the tests have only been partially successful, the Soviets do have an operational ASAT system, and we do not. We cannot expect the Soviets to negotiate a ban on weapons in space if we pursue a course of either stopping our own development of such weapons or pursuing this development willy-nilly, irrespective of the consequences for arms control.

"The ability to destroy Soviet satellites will not deter the Soviets from destroying our vital satellites during time of war."

The lack of such an agreement would seriously imperil our national security. While the Soviet Union can depend upon land lines of communication in a European conflict, we would have to depend upon satellite communications. Already, 70 percent of American military communications travel via satellite. Moreover, our military satellites provide us with communications and intelligence, and are also vital for verifying Soviet arms control treaty compliance. The ability to destroy Soviet satellites will not deter the Soviets from destroying our vital satellites during time of war. Thus, in all respects, obtaining an effective, verifiable ban on weapons in space and weapons to be used against spacecraft is in our national interest.

(Cons, continued-on page 85)

PRO HEFLIN, cont. from page 82

call for the development of strategic defensive systems as a means of making nuclear weapons impotent and obsolete. If we raise ourselves above partisanship, as indeed we must, and look with open minds at what could represent a more stabilizing strategic policy, I believe we will come to agree that this initiative can signal a change in America's strategic policy that is likely to live in history as a dramatic turning point toward world peace. It puts us on a course that is fundamentally more secure and humane.

I believe America's scientists and engineers, who have brought this Nation to preeminence in world technology and to the Moon and back, can succeed in developing the defensive systems to make this peaceful vision a reality.

---

by Hon. Fred C. Ikle

U.S. Under Secretary of Defense for Policy

From a statement accompanying Mr. Ikle's testimony on May 18, 1983, before the Senate Committee on Foreign Relations in the course of hearings on pending resolutions calling for a ban on space weaponry.

THE TECHNOLOGICAL REVOLUTIONS in the possible uses of outer space have opened new opportunities—as well as threats—for national defense. Both United States and Soviet Armed Forces use satellite systems. U.S. military space assets provide support for military operations, such as: communications, command and control, warning, navigation, and weather information. In fact, space systems are used increasingly for command, control and communications. Our launch detection satellites and strategic warning systems contribute to our nuclear deterrence. Space systems also enable us to monitor compliance with arms control agreements.

"...the U.S. military use of space is consistent with international law."

Needless to stress, the U.S. military use of space is consistent with international law.

Our military space programs are not simply a reaction to Soviet space activities but are the result of our continuing evaluation of the best means of achieving our national security objectives. We see space as a region in which supporting military operations may be carried out. While our programs are not a reaction to those of the U.S.S.R., we must, of course, take account of Soviet space activities. As in other areas, the Soviet approach to space differs considerably from our own.

"...the Soviet Union [has] clearly signaled its recognition of space as an arena in which to conduct war."

With the development and employment of an orbital antisatellite weapon over a decade ago, the Soviet Union clearly signaled its recognition of space as an arena in which to conduct war.

In the past 10 years, the U.S.S.R. has been launching more than 75 spacecraft per year, a rate of four-to-five times that of the United States. Over the past few years, the rate has been close to 100 annually. The annual payload weight placed into orbit by the Soviets is even more impressive—660,000 pounds—ten times that of the United States. This level of effort reflects the importance the Soviets attach to their space programs. But it may also reflect some technological weakness in the longevity and flexibility of their spacecraft. Soviet military and military-related space programs range from extended manned missions, to meteorological, communica-

CON Continued from page 83

by Hon. Jim Leach

United States Representative, Iowa, Republican

From an address delivered on the floor of the U.S. House of Representatives on April 7, 1983. Rep. Leach is a member of House Committees on Foreign Affairs and Banking, Finance & Urban Affairs.

PRESIDENT REAGAN HAS CALLED upon the scientific community in our country to turn its great talents to the cause of mankind and world peace by developing space based antiballistic missile systems thereby, in the President's judgment, rendering nuclear weapons "impotent and obsolete."

Military strategists have for centuries stressed the need to occupy the "high ground." In the name of peace, the President asked the American people to lay down the technological gauntlet to the Soviet Union and launch what may prove to be the most exotic, expensive, and dangerous arms race yet, a race to dominate the ultimate "high ground"—outer space.

"If the United States and the Soviet Union do not pull back from the madness of the arms race, the era of space soldiers could be less than a decade away."

The concept of weapons in space has long been a staple of popular entertainment. But Buck Rogers is no longer science fiction. Yesterday's comic book fantasia is today's reality. If the United States and the Soviet Union do not pull back from the madness of the arms race, the era of space soldiers could be less than a decade away.

Security in the nuclear age implies being technologically second to none. But skeptics of the President's proposal point to towering obstacles involved in reliance on space-based deterrence:

First, orbiting battle stations, for instance, would be sitting ducks for counterforce weaponry;

Second, at relatively little cost, decoys and counters could be developed to confuse targeting systems and reduce the reliability of space-based weaponry;

Third, to provide effective deterrence, space based weapons would have to be 100 percent reliable; if only 1 percent of the Soviet Union's current missile force survived a launching, up to four nuclear warheads, each with a destructive power 30 times that of the bomb that destroyed Hiroshima, could be available for targeting on each of the 50 States;

Fourth, even if laser and particle beam technology proves generally effective against missiles, the possibility of developing other relatively invulnerable delivery systems remains; nuclear weapons, after all, can be carried by hand or transported in sail boats; 10 years ago, in fact, an American missile was stolen from a West German defense site and after dismantlement, transferred by mail to the Soviet Union; while the postal service is an unlikely strategic force—nuclear weapons not being as easily delivered as junk mail—the potential remains, without sizeable investment, to clandestinely place a weapon in another country and maintain detonation control from without; and

"...it is unlikely one side would allow the other to develop and put in place a weapons system without the other dedicating similar resources with similar effect."

Fifth, it is unlikely one side would allow the other to develop and put in place a weapons system without the other dedicating similar resources with similar effect.

Finally, and ironically, if one side appeared on the verge of establishing a foolproof defense system, incentives for the other to launch a preemptive strike would increase. Rather than enhancing global stability, the development of an invulnerable antimissile umbrella could precipitate the ultimate in brinkmanship. Strategic break-

(Continued on page 87)

PRO

IKLE, cont. from page 84

tions, navigational, reconnaissance, surveillance, targeting and antisatellite missions.

Since the U.S.S.R.'s successful launch of Sputnik I in 1957, the Soviets have pursued a vigorous and methodical program to exploit space for military purposes. The initial Soviet use of space for military applications occurred in 1961 with the launch of their first photographic reconnaissance satellite. Throughout the 1960's and 1970's, Soviet military space programs expanded in both scope and numbers. By now, these programs had developed into mature, integrated systems for the direct and indirect support of Soviet military forces, and with the capability to threaten low-altitude U.S. and allied satellites.

"On any given day, 70–110 Soviet satellites are in orbit, more than half of which serve primarily military purposes."

On any given day, 70-110 Soviet satellites are in orbit,more than half of which serve primarily military purposes. Some 85 percent of all Soviet space launches are primarily military or joint military/civilian missions.

It appears that the Soviets are developing a re-usable space system, similar to the U.S. space shuttle, and a smaller space plane. Orbital developmental test flights of the smaller vehicle have already occurred. These systems could be in regular use within a decade and will further expand the military flexibility and capability of the Soviet space effort.

Soviet manned space missions are becoming increasingly complex and constitute the single most extensive element of the Soviet space program. After accomplishing many firsts in the early 1960's, including the first man in space, the Soviet manned program was momentarily overshadowed by the U.S. manned program during the late 1960's. Since 1971, the Soviets have placed seven space stations in orbit. The first Salyut I manned space station was launched in 1971. A second type of Salyut station was launched in 1973. Both were capable of conducting military research.

By 1977, the Soviets had developed the capability to resupply and exchange personnel on their Salyut space stations. On three occasions the Soviets have conducted manned missions lasting as long as 6 months. With completion in 1982 of the 211 day mission, the Soviets set a new record.

"The Soviet commitment to their manned space program is growing."

The Soviet commitment to their manned space program is growing. The development of a large manned space station by about 1990 to maintain a military presence in space is, we believe, one of the goals of the new heavy-lift launcher systems now in development. The Soviets also will use the heavy-lift space boosters to orbit even larger space stations and space modules before the end of the century. Such space stations could weigh more than 100 tons and be able to support a large crew for extended periods without replenishment.

The U.S.S.R.'s introduction, application and known future development of space weapon systems point to a coordinated program involving:

The present generation of antisatellite vehicles, now operational and designed to destroy low-orbiting satellites.

A very large, directed energy research program including the development of laser-beam weapons systems which could be based either on the ground, or aboard the next generation of Soviet antisatellite systems or Soviet manned space stations.

The operational Soviet antisatellite system has the capability to destroy U.S. space systems in near-Earth orbit. The Soviets conduct yearly tests to practice satellite interception and to refine the ASAT system. We believe that one of the purposes of the Soviet Union's space weapons program is the development and deployment of a space-based laser. The Soviets could launch the first prototype of a

(Continued on page 88)

CON **LEACH,** cont. from page 85

throughs in an era where weapons themselves are of civilization-destroying proportions destabilize the nuclear balance and thus generate Strangelovean calculations that defy normality and, potentially, morality.

Until Hiroshima, the history of warfare could be characterized as a vacillation between the preeminence of the forces of offense and those of defense.

A maginot line mentality which refuses to recognize that there is no shield mightier than the nuclear sword undercuts any rationalization for arms control. It leads not only to questioning of the desirability of seeking future arms agreements, but to a reappraisal of past ones.

To date, arms control advocates have criticized the President for not pursuing new arms agreements as forthrightly as they would prefer. The President's avowed intention to launch a new arms race in space raises a more alarming specter: the possibility that an American President would renege on the only agreement legally in force between the superpowers.

"The President contends that only if the United States demonstrates a commitment to develop new weapons will the Soviet Union come to the bargaining table..."

The 1972 ABM treaty declares: "Each party undertakes not to develop, test, or deploy ABM systems or components which are sea based, space based, or mobile land based." The administration holds that merely conducting research of the type hinted in the President's speech does not violate SALT I, but clearly fulfillment of the President's loosely described "vision of the future"renders meaningless the terms of the agreement.

The President contends that only if the United States demonstrates a commitment to develop new weapons will the Soviet Union come to the bargaining table, and only by realistically appraising Soviet intent can we fashion appropriate foreign policy initiatives and responses. The President's two principal speeches, however, may prove counterproductive. In his "Star Wars" speech, the President challenged the sanctity of past agreements and implicitly the word of the U.S. Government. In his "Darth Vader" pronouncements to Evangelical Christians in Orlando, he implied agreements might never be possible with the Soviet Union.

Describing the Soviet empire as "the focus of evil in the modern world," President Reagan imbued cold war rhetoric with holy war symbolism. If the Soviet Union is evil incarnate, any President who signs an arms control agreement presumably would put himself in the position of selling his country's soul to the Devil. It would perhaps be too harsh a judgment to conclude, as America's preeminent historian Henry Steele Commager recently did, that the Orlando speech was the worst speech ever delivered by an American President. But the implications for arms control must be considered worrisome.

"Time is running out on our ability to control space-age weapons."

Russians are a proud people. The Soviet system is repressive, but little good would seem to be served by political posturing. Now is the time to deescalate rhetoric and stop the nonsense of name calling. Global survival requires that at a minimum we posit sanity on the Soviet side and recognize that mutual self-interest demands a forthcoming approach to arms control.

Einstein once remarked that unleashing the power of the atom has changed everything except our way of thinking. Time is running out on our ability to control space-age weapons. If "Star Wars" is to remain fiction, statesmanship must catch up to the realities of modern science.

One of the foremost principles of arms control is that it is far easier and more manageable to make agreements prohibiting what has not taken place than to

(Continued on page 89)

PRO IKLE, cont. from page 86

small space-based laser antisatellite weapon in the late 1980's or early 1990's. A system capable of attacking other satellites within a few thousand kilometers range might be possible in the 1990's. Space-based ABM systems could be tested in the 1990's, but probably would not be operational until after the turn of the century.

The Soviets have steadily increased their space photographic and electronic reconnaissance effort since the early 1960's. Each year over 50 of these satellites are launched to support military forces on a daily basis. The Soviet military space program also reflects an ever-increasing use of space for world-wide surveillance and warning. The Soviets have brought a number of United States and allied military forces under surveillance by these space-based systems. The surveillance satellites include an ICBM launch detection system and ocean surveillance systems, such as the two nuclear-powered satellites that caused worldwide alerts during their breakup and reentry into the Earth's atmosphere in 1978 and early 1983. Soviet efforts in the surveillance field are expected to lead to a multi-satellite detection, surveillance and attack-warning system against strategic and non-strategic ballistic missiles and possibly bombers as well.

"The Soviet military space program... reflects an ever-increasing use of space for world-wide surveillance and warning."

The Soviets also are increasing their use of space systems for command, control, and communications. Since the mid-1960's when their first communications satellite was launched, the U.S.S.R. has continued to improve and expand its communications satellite programs to support its political leadership and its military, diplomatic and intelligence mission.

The Soviets have embarked on an ambitious expansion of their communication satellite program that will significantly enhance their global command, control and communications capability. Over the next 10 years, the Soviets will develop and deploy an even more advanced series of communication satellites, some of which might relay transmissions from manned orbital command and control platforms.

Let me now turn to our own activities. In support of our national security, the Department of Defense acquires and operates space systems and pursues space-related research and technology development projects.

"..Soviet development of an operational antisatellite capability presents the potential for space to become a hostile environment."

As noted, Soviet development of an operational antisatellite capability presents the potential for space to become a hostile environment. Therefore, the DOD space policy directs that military space systems, including essential ground elements as well as orbiting spacecraft, be designed, developed and operated to enhance their survivability and endurance.

Since 1977, it has been U.S. policy to pursue the continued development of an operational, non-nuclear antisatellite capability. If we have a credible retaliatory capability, we are better able to deter attacks against our space systems.

We are currently signatories of at least three treaties which affect certain military activities in space: the Outer Space Treaty, the Limited Test Ban Treaty, and the Antiballistic Missile Treaty.

The Outer Space Treaty prohibits, on the Moon and other celestial bodies, the establishment of military bases, installations, and fortifications, the testing of any types of weapons, and the conduct of military maneuvers. This treaty also prohibits the placement in orbit around the Earth, installation on the Moon or other celestial bodies, or stationing in outer space of any objects carrying nuclear weapons or any other "weapons of mass destruction." The testing or orbiting (in outer space proper) of weapons using conventional explosives is not prohibited.

(Continued on page 90)

CON **LEACH,** cont. from page 87

attempt to restrict weapons or troops deployments which have become a standardized part of a particular country's arsenal or which are current de facto military situations. SALT I restrictions on ABM systems were successfully developed precisely because they were agreed upon before, rather than after, significant deployment. The logic that led to the SALT I agreement prevails today. Security is better enhanced by arms control than by arms races. Space should be explored, not exploited.

It has been noted by many that President Reagan has more potential to reach arms control agreements than a President perceived to be more liberal, because he commands the respect of those who might be expected to object to serious arms control. Like Nixon going to China, Ronald Reagan can go the the Moon on arms control. The President's critics must understand that administration initiatives—the proposal of a one-third reduction in nuclear warheads; the zero-option INF position; the recent draft convention on chemical weapons; and, most importantly, the willingness to stay at the bargaining table—represent a first step. The President's supporters, however, must understand that the successful conclusion of any agreement will take greater flexibility and professionalism than has so far been evidenced. Perspective is demanded on all sides, but global patience is wearing thin.

"Security is better enhanced by arms control than by arms races. Space should be explored, not exploited."

Swords can no longer be blunted by shields. They must, as Scripture implores, be beaten into plowshares.

---

by Daniel Deudney

Senior Researcher, Worldwatch Institute

From testimony presented on April 14, 1983, before the Senate Committee on Foreign Relations in the course of hearings on pending resolutions calling for a ban on space weaponry.

BUFFETED by the MAD (mutually assured destruction) men telling him to perpetually assure our destruction and the NUTS (nuclear utilization theorists) telling him to prepare to fight nuclear wars, President Reagan looked to the heavens in hope of finding salvation from our deepening peril.

He looked in the right direction. Space technology can be the cornerstone of an alternative security system, the foundation of an international order that does not rely upon evermore massive arsenals of nuclear weapons.

If we can avoid using space as another arena for conflict and instead use it as a medium for mutual benefit, we will have taken a giant step toward enduring peace.

"If we can avoid using space as another arena for conflict... we will have taken a giant step toward enduring peace."

Space technology is at the core of the present superpower standoff. The first military space technology, ballistic missiles, used space as a corridor for high speed unobstructable attack, thus enabling the Soviets to outflank American dominance of air power and directly threaten the United States. The second use of space technology for military purposes, reconnaissance satellites, enabled the United States to roll back the veil of Soviet secrecy and monitor in detail the Soviet military machine.

The ominous movement over the last decade toward fighting a nuclear war is in large part the consequence of the satellite "force multipliers": geodetic satellites to

(Continued on page 91)

PRO **IKLE**, cont. from page 88

The 1972 ABM Treaty prohibits the development, testing, and deployment of space-based ABM systems and components (article V). Should future technology bring forth new ABM systems "based on other physical principles" such as lasers and particle beams, as opposed to those employed in current systems, it was agreed that limiting such systems would be discussed before deployment in accordance with the treaty's provisions for amendment.

In conclusion, let me say a few words about the President's initiative on strategic defense. The President decided that we embark on a program to counter the Soviet missile threat with measures that are defensive. He directed a comprehensive and intensive effort to define a long-term research and development program toward the goal of eliminating the threat posed by nuclear missiles. This development could be—indeed should be—complemented by arms control measures.

"The President decided that we embark on a program to counter the Soviet missile threat with measures that are defensive."

In accordance with the President's decision, the Defense Department, in cooperation with other agencies, has initiated a two-pronged effort: one to explore and prioritize the technologies, and the other to develop and define the policy and strategy options. We are not envisioning a single system to intercept and defend against all missile attacks. Our research is designed to explore a defense network—a series of systems not necessarily based on the same technology or physical principles—which taken together will provide an effective defense against nuclear ballistic missiles for us and our allies. We recognize full well that this is a long-term effort whose fruits may not be available until the next century.

Because this is a long-term effort we need to be clear, as the President explained, that we must continue for the interim to rely on deterrence to preserve the peace. We also must—and will—continue to pursue agreed reductions in nuclear arms that are balanced, and verifiable. Because our search for defensive technologies has the goal to reduce the threat of ballistic missiles, it is fully consistent with the arms reduction effort we are pursuing today in the START negotiations. It supports those efforts by offering the prospect that the effectiveness and role of ballistic missiles may be reduced sharply in the future. The President's initiative is, of course, also fully consistent with existing arms control agreements. While the ABM Treaty prohibits the development, testing or deployment of ABM systems, it does permit research.

"The essence of the President's decision on strategic defense... is that it opens up alternative avenues to preserve the peace in the nuclear age."

The essence of the President's decision on strategic defense, in my view, is that it opens up alternative avenues to preserve the peace in the nuclear age. President Reagan's successors—in the next decade, or in the first decade of the next century—need not have their options limited by the strategic notions that were fashionable in the 1970's. Our strategic planning has been restricted far too much by the idea that defensive systems are bad and that we can and must, indefinitely, remain locked into a confrontation of all-powerful, offensive missile forces. We owe it to the next generation to make a determined search for better alternatives.

(Pros, continued on page 92)

CON **DEUDNEY,** cont. from page 89

improve the accuracy of missiles; communication satellites to coordinate strikes or retaliation; and navigation satellites (such as the NAVSTAR GPS) to make submarine launched missiles as accurate as land-based ones. The present effort to upgrade U.S. surveillance satellites by giving them "real time" data links through relay satellites will turn an arms control monitoring system into a war-fighter for targeting mobile forces and performing postattack damage assessment.

Regulating these war-fighting information services without constraining important civilian and arms control verification treaties would be difficult, if not impossible. This makes it all the more imperative that agreements limiting long-range ballistic missiles be signed in the near future.

"..the next move in this deadly game of leap-frog may well be a Soviet laser orbital battle station intended to cripple satellites."

We are now at a major turning point in the military use of outer space—the beginning of a race to put weapons into space.

The first antisatellite weapon, ASAT, an American system, employing nuclear warheads, was tested and deployed. It was dismantled because it was too indiscriminate in its destructiveness and, with the Limited Test Ban, could no longer be tested.

The second ASAT, a Soviet orbital rendevous system using conventional explosives, has been tested some two dozen times with about a 50 percent rate of success. This system, which cannot reach most U.S. military satellites, is launched from a large, distinctly configured Soviet rocket requiring extensive support facilities, and providing plenty of warning time.

The United States is about to begin testing an air-launched direct ascent system that will destroy through high speed collision. The U.S. system will be capable of striking a high percentage of Soviet military satellites, is small and hard to distinguish from other air launched missiles, and will give little warning time.

If history is any guide, the next move in this deadly game of leap-frog may well be a Soviet laser orbital battle station intended to cripple satellites. Given the Soviet tendency to deploy much earlier in the development cycle than the United States, and the immense technical problems associated with such a system, it will probably have negligible capability—except to reduce warning time. But as with Sputnik the psychological impact will probably be traumatic, leading the United States to embark upon an ambitious crash program to put battle stations into orbit. The result will be a full scale arms race in space.

"With weapons in space every satellite malfunction could be the harbinger of a surprise attack."

What are these weapons for and what strategic purpose will they accomplish? How will our security be affected?

The antisatellite capabilities will be important components of a first strike against early warning satellites. Far less plausible is their use in a protracted nuclear war—their official justification.

ASATs will, however, increase the chances for accidental nuclear war. The eyes and central nervous system of our already far flung nuclear strike forces are in space. With weapons in space every satellite malfunction could be the harbinger of a surprise attack. The Archduke Francis Ferdinand of World War III may well be a critical U.S. or Soviet reconnaissance satellite hit by a piece of space junk in a crisis situation.

Predicting how the more speculative larger scale systems would be used hinges on many unknowables. But it seems improbable that they would be capable of stopping a full-scale pre-planned first strike. Far more plausible is their use as part of a first strike to "mop up" those missiles that escape destruction on the ground.

PRO Continued from page 90

by Lieutenant General Daniel O. Graham

United States Army, Retired

From testimony presented on April 14, 1983, before the Senate Committee on Foreign Relations in the course of hearings on pending resolutions calling for a ban on space-based and space-directed weapons. Gen. Graham is Director of High Frontier, an organization concerned with the U.S. defense posture relative to space weapons systems.

I BELIEVE IT WOULD BE A TRAGEDY INDEED for the United States to follow the Soviet lead in banning all weapons in space. Two weeks after the first flight of the U.S. space shuttle Columbia, Premier Breshnev of the Soviet Union came forward with a public announcement that a treaty should be signed banning all military weapons in space.

"...it would be a tragedy indeed for the United States to follow the Soviet lead in banning all weapons in space."

From the Soviet point of view, this was a smart move, and indeed it was followed up later by the Soviet proposal for a U.N. treaty to that effect. It was good strategy for the Soviets because they recognize the fact that the United States had reached a position in space technology where the Soviet advantage in nuclear first strike capability residing in their superior force of long-range ballistic missiles could be nullified. The Soviets knew that the shuttle represented a transportation system to space over which the United States could move the men and material necessary to protect the free world from Soviet nuclear first strike or nuclear blackmail.

To follow the Soviet lead by banning all weapons in space, as opposed to banning nuclear weapons in space which has previously been agreed to, would be to deny to the United States our only chance to deliver ourselves and our posterity from the brooding menace of the balance of terror doctrines of mutual assured destruction. By putting into space a nonnuclear defensive system, we can deny to the Soviet Union any hope of an effective first strike with their huge intercontinental ballistic missiles.

A system such as that proposed by High Frontier would have no capability whatever of killing a single Russian, but could deny to the Soviet Union its first strike capability, not an effective retaliatory capability. Such a system could be deployed quickly and at reasonable cost if we use the technology currently available to us, already paid for by the taxpayers.

"By putting into space a non-nuclear defensive system, we can deny to the Soviet Union any hope of an effective first strike..."

Once in place, we can discard the awesome doctrine of mutual assured destruction and base our deterrence on a new strategy of assured survival. As President Reagan has said, we will then be able to save lives, rather than merely threaten to avenge them.

The historic opportunity will surely be lost if the Senate of the United States persuades the Government to adopt the policy of banning even such patently defensive nonnuclear systems in space. Indeed, such a policy will perpetuate the mutual assured destruction doctrine and force us for the foreseeable future to live as hostages in the balance of terror strategic situation in which we find ourselves today.

For those who are most interested in arms control, I should point out that our arms control negotiations to date have been based on the attempt to maintain a balance within the balance of terror. If indeed we go to space-borne defense, it is perfectly logical to approach the Soviet Union this way, to say Ivan, you have said

(Continued on page 94)

CON **DEUDNEY,** cont. from page 91

Large-scale space weapons would be an example of what I call a destruction entrusted automatic device (DEAD). Space weapons could never be commanded and controlled by humans. A space laser, for example, would have about five minutes to detect, target and engage an ICBM in the boost phase. One Department of Defense analyst put it this way. "We would have to delegate the decision-making to the weapon system itself and we have had no experience in that type of operational system." To start a nuclear war in the MAD era would have required a major political misjudgment; with space weapons a machine malfunction would be sufficient.

Large-scale space weapons would be but one example of our potentially fatal drift to adopt DEAD strategies. Perhaps the most widely discussed strategem involving DEAD is "launch on warning." As attacks against even the most hardened missile silos grow in probable success, there is a strong temptation to prepare to launch the vulnerable missiles before the barrage of attacking warheads arrive. With somewhere between 15 and 30 minutes warning and response time for intercontinental ballistic missiles the civilian leadership is, as they say in Pentagonese, "out of the decision loop." In simple terms, the military would have the authority as well as the ability to fire a salvo of nuclear missiles in response to radar and computer images of attack. Thus far neither the United States nor the Soviet Union has adopted—at least publicly—a launch on warning strategy, although U.S. military planners speak of such a posture to make the MX "survivable." And the Soviet leaders have said they will be forced to place its forces on such hair-trigger alert, if the NATO deploys the Pershing II missile, capable of striking hardened targets deep within the Soviet Union in 5-8 minutes. "Speed" observes U.S. Defense official Fred Ikle, "is the tightening noose around our neck."

"Space weapons could never be commanded and controlled by humans."

The construction of an anti-ballistic missile (ABM) system capable of shooting down on-coming nuclear missiles would also require the delegation of control to machines. During the late 1960s when the United States, after acrimonious international debate, decided to build a limited anti-ballistic missile system, a major objection leveled by critics of the plan was that the nuclear anti-missiles would have to be fired without Presidential authorization and, in the case of close-range "terminal defense," without human intervention. Fortunately, the superpowers agreed in the ABM Treaty of 1972 not to deploy missile defenses, sparing the world another step toward self-destruction.

"...space weapons promise to bring humanity to the edge of cybernetically-initiated annihilation."

The accidental triggering of a "defensive" system seems at first glance to be far less ominous than the accidental launch of a nuclear missile. Yet with space weapons this distinction largely disappears. Since both sides would have hundreds of very large automatically controlled battlestations in orbit, the likely target of a malfunctioning satellite would be another such satellite (perhaps even one of its colleagues). Since any first strike would require as a first step the attack on the other side's "defensive" satellite system, the inadvertant destruction of such satellites would be indistinguishable from a first strike. Thus a space-based ABM or ballistic missile "defense" system would be far worse than a terrestrial-based one because a malfunctioning earth-based unit would not destroy a potential antagonist's critical military systems. Instead of offering an escape from the tightening nuclear noose, space weapons promise to bring humanity to the edge of cybernetically-initiated annihilation.

(Continued on page 95)

PRO GRAHAM, cont. from page 92

that you do not wish to first strike the United States. You will excuse us if we worry about that since many of your weapons systems seem to be designed to do just that.

We are therefore going to put into space a defensive system which will deny any country the capability of first-striking the United States with nuclear ballistic missiles. Since you have no intention of doing that, you won't mind, of course, will you?

"...High Frontier uses kinetic energy kill; that is, a kill of the Soviet weapons with pellets, like buckshot."

Further, you may not believe the United States when we say we have no intention of first-striking the Soviet Union. But if you Soviets don't believe us, then we invite you to put a similar system in space yourself.

I should point out that the High Frontier system that I have spoken of does not employ lasers and does not employ particle beam weapons or any futuristic Buck Rogers system. In fact, High Frontier uses kinetic energy kill; that is, a kill of the Soviet weapons with pellets, like buckshot.

If you worry that this is not technically feasible, I would like to call your attention and the attention of your staffs to a document recently declassified by the Department of Defense which was Project Defender. In Project Defender, in 1962, 20 of the best scientists within the Department of Defense, backed by a staff of 5,000 technicians and administrative personnel, came to the conclusion that a defense such as High Frontier's could have been deployed by 1968.

So we are not talking Buck Rogers when we back the President's call for a defense in space. We do not have to have lasers or particle beam weapons, although High Frontier has no objections to such weapons and a second generation may include them. The fact of the matter is that within 5 or 6 years, at a cost not of many billions but of $15 billion, a strategic defense can be had by this country. If President Reagan runs again, he may see a space-borne defense against the long-range Soviet ballistic missiles during the period of his Presidency.

"...within 5 or 6 years, at a cost of...$15 billion, a strategic defense can be had by this country."

Now we have had contests that what we say will cost much more. As a matter of fact, we had correspondence from the Deputy Secretary of Defense, who said that we were wrong, that in fact it would cost $50 billion.

Well, we don't agree with the Department of Defense. We think it will cost far less. But even if it did cost $50 billion, this is less than it would have cost us to deploy the racetrack deployment scheme for MX. And all that would have done is to add 200 more missiles to our inventory.

We offer to this country once again what the country should be able to expect from its government, which is protection against the worst threat that the United States of America has ever faced, and that is the threat of destruction within 35 minutes of a Soviet decision to fire its long-range ballistic missiles.

That this is technically feasible was proved 20 years ago. All that is required today is the political will to do so. But also required is a realization that this new arena of human activity called space must be used to its utmost by the United States for the defense of this country and of its allies and for the promotion of industry in space and this should be done as quickly as technology will allow.

CON **DEUDNEY,** cont. from page 93

Space war will also largely preclude the peaceful use of outer space. We rightly think of space as infinitely vast, but in doing so we forget that the earth's orbital space is limited and subject to the same problems of crowding and resource degradation we face on earth. Already space junk—small bits of debris flying about in various odd orbits— is a growing problem. Further ASAT tests involving explosions and collisions will add greatly to this problem. Testing the X-ray laser system would damage important civilian satellites with electromagnetic pulse (EMP). By the late 1980s over 100 communication satellites in geosynchronous orbit, worth between five and ten billion dollars, will be in jeopardy. In a very real sense we face an either/or choice: science, information services, and earth monitoring from space—or weapons in space.

"Space war will also largely preclude the peaceful use of outer space."

The present arms control regime for space weapons—the *Limited Test Ban Treaty,* the *ABM Treaty* and the *Outer Space Treaty* has worked remarkably well, but contains important loopholes through which space weapons can pass. To abandon these treaties because of their loopholes would be like dynamiting a leaky dike at high flood rather than plugging the leaks.

Fortunately, we are at a stage where weapons in space can be stopped before they are ever extensively tested and deployed. Space weapon development is no further along than air war was when World War I biplane reconnaissance pilots carried hand guns. Most importantly, because so little has been tested, truly comprehensive controls are relatively easy to construct and verify.

The control of weapons in space simply clears the stage for the use of space technology to improve both arms control verification, and our relations with the Soviets. This positive space security agenda emphasizes the unique role of space technology in providing *mutual assured security* and mutual benefits.

First, *expand the use of space for crisis monitoring.* The recently proposed establishment of an orbital joint U.S.-Soviet command center should be a priority.

Second, *establish an International Satellite Monitoring Agency (ISMA).* An ISMA would permit the Security Council to monitor crises and border disputes and would lay the groundwork for monitoring compliance with the treaties banning chemical and biological warfare and environmental modification.

"Either we move now to comprehensively ban weapons from space or we will have a major new arms race on our hands."

Third, *conduct joint missions with the Soviets.* A U.S. Administration, looking for a bold, high visibility, quick pay-off way to cut through gathering clouds of suspicion and war, would find a joint U.S.-Soviet manned space mission particularly appealing.

Unlike in 1976 when the Apollo-Soyuz rendezvous was a meeting of two parallel systems, the space shuttle and the Salyut stations are perfect complements for each other. What better way to find out what's going on in Soviet space stations or to allay Soviets' suspicions about the shuttle than to take each other for a ride? More routine cooperation in space and the consequent commingling of space scientists would make much harder concealed weapons work.

The world is at a critical juncture. Either we move now to comprehensively ban weapons from space or we will have a major new arms race on our hands. Space technology can be the foundation of an alternative security system—if we ban weapons now.

Treaties Involved

From page 69

not reconstructed, are said to require an on-site inspection agreement. According to analysts, the Soviet SS-9 will probably continue in production for use as a satellite launcher. Small ASAT payloads could be hidden from on-site investigators or moved off-base until after they had left.

U.S. defense planners are concerned that only a relatively few American satellites would have to be "neutralized" to have a serious effect on our strategic posture. Even if only a few Soviet ASATs escape the verification process, the result would be a severe impact on national security.

Action in the Current Congress

From page 73

verifiable ban on ASATs; and (2) that pending such an agreement, such tests are necessary for the national security."

Separately, on July 21, Senator Wallop introduced an amendment to increase funding for space-based laser programs by $125 million. He also sought to transfer the program from the Defense Advanced Research Projects Agency to the Army's Ballistic Missile Defense Office. The amendment was defeated 65-27.

DOD Appropriations Bills

During mark-up of the DOD Appropriations Bill, H.R. 4185, the House Appropriations Committee deleted $19.4 million for procurement of the U.S. ASAT pending a report on the President's policies regarding arms control in space.

The Senate disagreed. During conference a compromise was reached. Money will be withheld until a report is submitted, after which it may be spent. The report must be submitted by March 31, 1984. The bill passed both Houses and was signed into law on December 8, 1983.

FY84 Funding

For Fiscal Year 1984, DOD requested $9.9 billion for space-related activities. Congress appropriated that amount, although funding within some categories was redirected.

The DOD Authorization Bill was signed into law on September 24, 1983 (Public Law 98-94). The Military Construction Authorization Bill was signed into law on October 11, 1983 (Public Law 98-115) and the Military Construction Appropriations Bill became law on the same day (public Law 98-116).

Congress denied $2.75 million requested by the Air Force for advanced military manned space systems, such as "space cruisers." Congress also approved $559 million requested for the Space Shuttle in the DOD Authorization and Appropriations measures—$337.4 million for research and development; $195.3 million for procurement; and $26.84 million for activation of the Vandenberg shuttle launch site.

In the Military Construction Bill, however, there was disagreement over funding for items relating to Space Shuttle facilities. In considering the Military Construction Appropriations Bill, the House deleted $6.6 million for construction of a shuttle external-tank area icing protection facility at Vandenberg, and $700 million for security modifications at NASA's Johnson Space Center. The Senate approved the funding and the conference report approved the icing protection facility, but adopted the House position on denying funding for security modifications at the Johnson Space Center; and denying $6 million of the $14 million requested for Vandenberg security modifications.

Other Space Programs

Congress approved virtually all requested funding for space-related items in the DOD budget, including $335 million for NAVSTAR; $220 million for AFSATCIM; $158 million for the Defense Satellite Communications System (adding language to permit multi-year procurement for this system); $61 million for meteorological satellites; $123 million for FLTSATCOM; and $150 million for MILSTAR. Funding for the Integrated Tactical Surveillance System, including space-based radars to track ships, was reduced from $30.2 million to $12 million, mainly because of congressional concern that projects within the ITSS category had been separated out and require review.

FY85 Funding

Funding levels for FY85 have not been determined. Two approaches to funding the ballistic missle defense development program have been suggested. The first is "fiscally constrained," with recommended levels of $1.3 billion in FY84; $1.9 billion in FY85; $2.5 billion in FY86; $3.1 billion in FY87; $3.7 billion in FY88; and $4.3 billion in FY89. The second is "technology limited," with recommended levels of $1.3 billion in FY84; $2.3 billion in FY85; $3.4 billion in FY86; $4.3 billion in FY87; $4.6 billion in FY88; and $4.9 billion in FY89.

FOREWORD

This document was prepared by a panel organized under the auspices of the Union of Concerned Scientists. The participants were:*

Kurt Gottfried, **Panel Chairman**, Member, Board of Directors, Union of Concerned Scientists; Professor of Physics and Nuclear Studies, Cornell University.

Hans A. Bethe, Professor of Physics Emeritus, Cornell University; Nobel Laureate in Physics; Chief, Theoretical Division, Manhattan Project; Member, President's Scientific Advisory Committee (1957-60); Strategic Military Panel (1957-69).

Richard L. Garwin, IBM Fellow at the Thomas J. Watson Research Center; Member, President's Science Advisory Committee (1962-65) and (1969-72); member, Defense Science Board (1966-69).

Noel Gayler (Admiral, USN, Ret.), former Director, National Security Agency; former Commander-in-Chief, U.S. Forces in the Pacific; former Deputy Chief of Naval Operations (Research and Development).

Henry W. Kendall, Chairman, Board of Directors, Union of Concerned Scientists; Professor of Physics, Massachusetts Institute of Technology.

Franklin A. Long, Professor Chemistry Emeritus, Cornell University; former Associate Director, U.S. Arms Control and Disarmament Agency.

Leonard C. Meeker, member, Board of Directors, Union of Concerned Scientists; U.S. Ambassador to Romania (1969-73); Legal Advisor to the Department of State (1965-69).

Carl Sagan, Professor of Astronomy and Space Sciences and Director, Laboratory for Planetary Studies, Cornell University.

Herbert Scoville, Jr., Deputy Director, Research, Central Intelligence Agency (1955-1963); President, Arms Control Association.

John Steinbruner, Director of Foreign Policy Studies, Brookings Institution, 1978-present; Associate Professor of Organization and Management, Yale University, 1976-1978.

* The affiliations listed are for purposes of identification only.

TABLE OF CONTENTS

Foreword
(1) Summary
(2) Current U.S. and Soviet Space Assets and ASAT Systems
(3) A Treaty Limiting ASAT Weapons
(4) The Relationship Between ASAT and ABM
(5) The ASAT Threat With and Without a Treaty
(6) Verification and Residual Risks
(7) Comparison with the 1981 Soviet Draft Treaty
Notes
Appendix I: A Treaty Limiting Anti-Satellite Weapons.
Appendix II: Answers to Questions Posed by Senate Foreign Relations Committee.
Appendix III: U.S. and Soviet Military Satellite Systems (Tables 1 and 2)

Richard L. Garwin, Noel Gayler and Kurt Gottfried presented a summary of this report at a hearing, called for this purpose, before the Senate Foreign Relations Committee on May 18, 1983. The position of the Reagan Administration was presented by Kenneth Adelman, Director of the Arms Control and Disarmament Agency, and by Fred C. Iklé, Under Secretary of Defense for Policy. The printed record of the hearing includes a somewhat briefer version of this document. Responses to the written questions posed by Senators Claiborne Pell and Larry Pressler are reprinted here as Appendix II.

The panel has benefitted from suggestions or criticisms by Robert W. Buchheim, Abraham Chayes, Daniel Deudney, William J. Durch, Donald L. Hafner, Spurgeon Keeny, Walter Slocombe, and Herbert F. York. The panel would also like to express its gratitude to Peter Didisheim, Kathleen Gilroy, Charles Monfort, John Pike, Howard C. Ris, Jr., Joshua Sarnoff, Irene Silverman, Nancy Stockford, and John Tirman.

38-036 O - 84 - 75

1. SUMMARY

Satellites give the United States prompt, precise, and irreplaceable intelligence about Soviet strategic forces. They provide an invaluable view of many other aspects of Soviet military capabilities and activities. In a crisis, they would allow each side to watch the movements of the other, to gauge its objectives and apprehensions. If hostilities were ever to break out between the superpowers, whatever hope there would be for controlling nuclear conflict and bringing it to an early end would largely rest on satellite surveillance, on the command of strategic forces via satellites, and on satellite communication between the adversaries.

But satellites are two-edged swords. They have a beneficial role in arms control, confidence building, and conflict resolution, but their unique ability to see, to hear, and to communicate greatly amplifies the effectiveness of the military forces that they serve. As a result, they become exceptionally tempting targets as soon as hostilities are about to begin.

In the 1960s, both the U.S. and the Soviet Union fielded systems having anti-satellite (ASAT) capabilities. The United States eventually dismantled its ASAT systems and adopted the position that its national security would be best served by abstaining from competition in ASAT weaponry. The Soviet Union, on the other hand, continued sporadic testing of a rather primitive device that can attack objects in low earth orbits.

By the latter part of the 1970s, the United States altered its approach, though a weapon-free space environment continued to be its goal.[1] The new tactics had both a military and a diplomatic component: a program to develop a satellite interceptor, and simultaneous negotiations towards a treaty that would ban the testing and deployment of ASAT weapons. These negotiations did not reach fruition during the Carter Administration,[2] and have not been pursued since then.[3] In the interim, both superpowers' ASAT programs have continued apace.[4]

In August 1981 the Soviet Union submitted to the United Nations a draft treaty calling for a "prohibition on the stationing of weapons of any kind in outer space." The United States has not responded to this initiative, nor has it offered any rationale for its failure to respond. If the United States continues to forego negotiations, it will have adopted a new strategy of ongoing confrontation for protecting its space assets. An era of strenuous competition in space weaponry will have begun, and even if one competitor does, on occasion, enjoy a fleeting advantage, the national security of both rivals will inexorably erode. Any threat to satellites, whether real or potential, will undermine confidence in the ability to deter attack. By the same token, an awareness that satellites are at risk will tend to destabilize a crisis. Even in times of peace, a keen rivalry in the development and testing of ASAT weapons is certain to cause friction, increase suspicions, undermine confidence in the ability to deter attack, and, perhaps, inadvertently spark a conflict.

Finally, the absence of any limitations on ASATs could allow an Anti-Ballistic Missile development program to masquerade as an ASAT program, in order to evade the ban on space-based ABMs of Article V of the ABM Treaty. As stated in that treaty, ballistic missile defense (BMD) undermines the deterrent value of an opponent's ICBM force. Therefore, even a minimal and ineffective BMD capability or an ASAT system that was not intended to have a BMD role, could be misperceived as a serious threat and trigger buildups of offensive missiles.

It does not take great powers of prophesy to predict such an erosion of security, for the analogy with the history of MIRV technology is both instructive and disturbing. In that case, the Soviet Union failed to foresee that the United States would develop MIRVs as a sophisticated response to a primitive ballistic missile defense of Moscow. Neither did the United States anticipate that the strategic benefit that it achieved with MIRVs would eventually boomerang—once the USSR had MIRVed its ICBMs—by putting at risk U.S. silo-based missiles. Today, finally, there is a broad consensus that strategic stability and the cohesion of the Western Alliance would have fared better had the United States abstained from introducing MIRVs. Nevertheless, there is a strange reluctance to recognize that this painful lesson applies directly to current trends in the arms competition in space.

It is in the long-term interest of both superpowers to minimize the likelihood of conflict in space. This is especially true for the United States. Some Soviet satellites do pose a direct threat to certain U.S. military forces, but these threats can be countered without ASATs. The United States, with its forces dispersed around the globe, is more dependent on military satellites than is the Soviet Union. The bulk of Soviet military forces are on or close to the Eurasian land mass, and the Soviets therefore rely primarily on ground-based and airborne communication facilities. Hence, the United States cannot protect its space assets by threatening retaliation against Soviet satellites. The U.S. should, instead, seek to constrain the further evolution of Soviet ASAT capabilities. Such constraints can only be achieved by negotiations that build on the established body of international law represented by the Test Ban Treaty, which forbids nuclear explosions in outer space, the Outer Space Treaty, which bans space-based nuclear weapons and weapons of mass destruction, and the ABM Treaty, which forbids the development, testing, and deployment of space-based ABM systems and protects satellites serving as "national means of verification."

Aside from these considerations that arise from a strictly military conception of national security, political factors of considerable weight also provide a strong incentive for negotiations. In the United Nations General Assembly, the allies of the United States proposed a resolution requesting the U.N. Committee on Disarmament to "consider as a matter of priority the question of negotiating an effective and verifiable agreement to prohibit anti-satellite systems." There is every indication that the Western allies of the United States will, in the U.N. General Assembly, propose that matters move from "considering the question of negotiating" to actual negotiations.

The United States, through its silence on the Soviet proposal, has in effect allowed the Soviet draft treaty to set the agenda for the international discussion of this issue. This is hardly a sound posture for the leader of the Western Alliance, and the world's preeminent military and civilian space power.

Whether the diplomatic and military objectives of the United States are being furthered by current policy has also been questioned by resolutions introduced in the U.S. Senate and House of Representatives calling for negotiations to prohibit the deployment of weapons that can damage or destroy objects in space, and for a moratorium on space testing of such weapons.[5] The recognition that space may become a hazardous no-man's land has also caused apprehension among the commercial users of American satellites.

It is the purpose of this report to examine the feasibility of negotiated limits on anti-satellite weapons. To this end, we shall compare the current status and potential capabilities of the U.S. and Soviet ASAT systems, and assess the military significance of the threat posed by these weapons. We shall find that:

1. The tested Soviet ground-based ASAT presents a rather unreliable, inflexible and ponderous threat to a small number of U.S. satellites in low orbits, but does not threaten high-orbit early warning, navigation and communication satellites essential to the strategic forces;

2. The U.S. ASAT, which is launched by an F-15 aircraft, if it performs according to specifications in impending flight tests, will present a prompt and flexible threat to the majority of Soviet satellites which are in low orbits, and a limited threat to Soviet early warning and communication satellites in highly elliptical orbits;

3. The U.S. ASAT could be modified to threaten satellites in high orbits, whereas the much heavier Soviet ASAT does not appear to be suitable for this purpose.

We therefore conclude that the existing ASAT capabilities do not yet present a serious threat to either superpower at this moment; that it is essential for the security of the United States to restrict the further growth of those capabilities; that negotiations towards that objective are feasible; and that it is urgent to begin such negotiations promptly.

To focus attention on issues that are likely to arise in such negotiations, we put forward an explicit treaty text. In view of our assessment of the current situation and its implications for the future, our draft treaty is, first and foremost, a ban on the testing of ASAT weapons. In essence, THE DRAFT TREATY REQUIRES THAT NO WEAPON THAT CAN DESTROY, DAMAGE, OR CHANGE THE FLIGHT TRAJECTORY OF SPACE OBJECTS, CAN BE TESTED IN SPACE,

OR AGAINST SPACE OBJECTS. Furthermore, the treaty obligates the parties to begin negotiations towards a prohibition on possession of ASATs as soon as the test ban is in place. The proposed text is for a bilateral treaty, because the accession of the Soviet Union and the United States is a prerequisite to a multilateral accord, and because U.S. security depends primarily on constraining Soviet capabilities.

We examine the problem of verifying compliance with such an ASAT test ban, and conclude that the hazards of a totally uninhibited competition in space weaponry are far greater than the potential threat posed by the tightly constrained evolution of ASAT capability that may be possible because of ambiguities in verification. Furthermore, we show that these residual risks can be reduced to an acceptable level by satellite defense measures (such as decoy satellites, maneuverability, etc.) that would cost much less than the program necessary if there were no negotiated constraints. These conclusions show that it is, on the whole, easier to detect violations of the treaty than to determine, in the absence of a treaty, which of an enormous array of permitted space activities pose a security threat.

Finally, on the basis of our findings, we argue that it would be advantageous for the United States to agree to an immediate moratorium on further ASAT space tests, and that the security of the United States would not be in jeopardy should such negotiations fail, or should a treaty be abrogated or circumvented by the Soviet Union.

2. CURRENT U.S. AND SOVIET SPACE ASSETS AND ASAT SYSTEMS

Negotiations towards restraints on further ASAT development must take into account the existing balance in U.S. and Soviet space assets and military capabilities.

SATELLITES

Since U.S. forces are spread across the globe, secure long-range communications are essential to U.S. security. For that reason, more than 60 percent of long-haul military communications are now transmitted via satellites, and that percentage is growing. There are no facilities on the earth's surface that provide a satisfactory replacement for this satellite system.

The Soviet Union's military forces are mainly on or near to the Eurasian land mass, and can readily communicate by using a large variety of ground-based and airborne facilities, in addition to satellites. Indeed, one can say that the Soviet Union uses its satellites as a back-up for its ground-based and airborne communications and intelligence gathering systems, while the converse is true of the United States.

The vulnerability of a satellite to attack is largely determined by the nature of its orbit. These fall into several categories: geosynchronous orbits, in which the satellite is stationary above a point on the the earth's equator at an altitude of about 22,000 miles; semi-synchronous orbits, with altitudes of about 12,000 miles; and low-earth orbits, at altitudes up to about 1000 miles. Satellites can also be in highly elliptical orbits that dip as low as several hundred miles and rise as high as geosynchronous orbits. Some U.S. satellites are in orbits that are considerably higher than geosynchronous orbits.

Tables 1 and 2 (Appendix III) provide an overview of the orbital characteristics, endurance, and missions of the major U.S. and Soviet satellite networks.[6-15]

U.S. satellites are considerably more sophisticated, more reliable, and far more long-lived than Soviet satellites. For example, the Soviet Union has only recently begun to retrieve high resolution film capsules without returning the satellite to ground, a technique that the U.S. has been using since the early 1960s. It is only within the last few years that the Soviets have been able to bring their early warning satellites to operational status.[7,15] Despite a large commitment to ocean surveillance from space, malfunctions reportedly prevented Soviet satellites from monitoring the Falkland war.[7]

U.S. Defense Department publications[16] claim that the Soviets have a much larger space program than the U.S., and cite the far larger number of Soviet launches and the payload placed into orbit as evidence for this claim. But the disparity in launch frequency is entirely accounted for by the much shorter life span of Soviet satellites, or by the need to retrieve the satellite itself.[6] Of the 101 Soviet satellites launched during 1982, over 50 percent were no longer in orbit or were out of operation by year's end.[7] Figure 1 documents this assertion in detail for the case of photo reconnaisance,[9] where Soviet satellites typically stay aloft for two weeks, while U.S. KH-11 satellites stay up for more than two years. Furthermore, a comparison of gross weight placed into orbit should not include the weight of the Shuttle orbiter; two Shuttle flights exceed the 660,000 lbs. annually put into orbit by the U.S.S.R.

The notion that the scope of the Soviet space program can be gauged by estimates of the Soviet space budget should also be treated with caution; if such a comparison were made in agriculture, it would lead to the conclusion that the Soviet Union has a more potent food-producing industry than the United States.

ASATs

The existing Soviet ASAT interceptor weighs three tons (See Fig.2). It is launched by the ground-based SS-9 booster (the very large predecessor of the current SS-18 ICBM booster) into an orbit close to that of its target. The interceptor then crosses the path of its target after one or two orbital revolutions, whereupon its non-nuclear warhead explodes, and the resultant shrapnel destroys the target satellite. All Soviet tests have used launchers at Tyuratam in Kazakhstan, and orbits within a very narrow range of inclinations (62 to 65 degrees).

The highest altitude reached thus far by the Soviet interceptor is reported to be about 1400 miles. Since the Soviet ASAT is ground-based, any particular weapon must wait up to 24 hours until the earth turns to bring the prey's orbit above the launch site.

It would appear to be very difficult to modify the Soviet system in order to threaten targets in high orbits. If it were to reach a satellite in geosynchronous orbit, it would have to be given an additional velocity of four kilometers per second, which would require an additional stage of propulsion about four times larger than the enormous booster that it already uses to reach low orbits. Therefore, the current Soviet system only threatens low-orbit space objects. About a third of all U.S. satellites fall into this category, and their most important national security functions are photographic and electronic surveillance of the earth's surface. U.S. satellites responsible for early warning, nuclear attack assessment, additional electronic intelligence, and military communications are in very high orbits, and are not vulnerable to the current Soviet ASAT.

NOTE: THE F-1M BOOSTER HAS NOT BEEN DISPLAYED. DETAILED BOOSTER CONFIGURATION IS CONCEPTUAL ONLY.

The U.S. ASAT system is based on quite different principles: it is not designed to go into orbit, but to intercept its quarry by "direct ascent," a far more difficult approach requiring extreme accuracy in position and time. The interceptor is the so-called Miniature Homing Vehicle (MHV), which is carried into space on a two-stage rocket that in turn is launched from a high altitude F-15 fighter plane (Figure 3). The MHV is a small cylinder with a diameter of about one foot that seeks its target by a combination of infrared telescopes, a laser gyroscope, and a set of small jets that can alter its trajectory (Figure 4). It destroys by direct impact at very high velocity.

Because it is plane-borne, the U.S. ASAT is, in principle, able to operate from any airbase that has adequate communication facilities. Interception of satellites in low orbits could take place within an hour if enough F-15s were suitably dispersed. The U.S. ASAT could not, however, be used to destroy the Soviet ASAT itself. Tethered decoys could readily be attached to the Soviet ASAT for the duration of its flight. In its present form the MHV cannot reach geosynchronous satellites, but this is not of great consequence at this time, because almost all Soviet satellites are in low or highly elliptical orbits.

By using a three stage booster, the U.S. ASAT should be able to reach geosynchronous targets. The whole system would weigh some 16,000 lbs., and could still be carried on an F-15.

The Soviet ASAT has been tested some twenty times since 1968. In the first test series (1968-1971), radar homing was used to approach the target, and the success rate was quite high (approximately 70 percent). Later tests used either a more sophisticated homing device, or a "pop-up" maneuver intended to provide a quick approach to the target. Both aspects of these tests were almost uniformly unsuccessful.[7]

Launches of the U.S. interceptor from an F-15 to a point in space are scheduled for later this summer, but tests against space targets are not scheduled until late in 1983 or early 1984.

These facts allow us to draw up a current balance sheet:

• The Soviet ASAT system is deemed to be operational by the U.S. Department of Defense on the basis of the 1968-71 tests, whereas the U.S. system is now ready for flight testing.

• The Soviet Union has most of its space-based assets in low earth (LEO) orbits, while the U.S. has many of its most important satellites in geosynchronous (GEO) orbits.

• The Soviet ASAT can only attack targets in low-earth orbits, and would require a very large booster to carry it up to geosynchronous targets (see Section 5

below). The U.S. interceptor could, with a three-stage booster, reach geosynchronous targets.

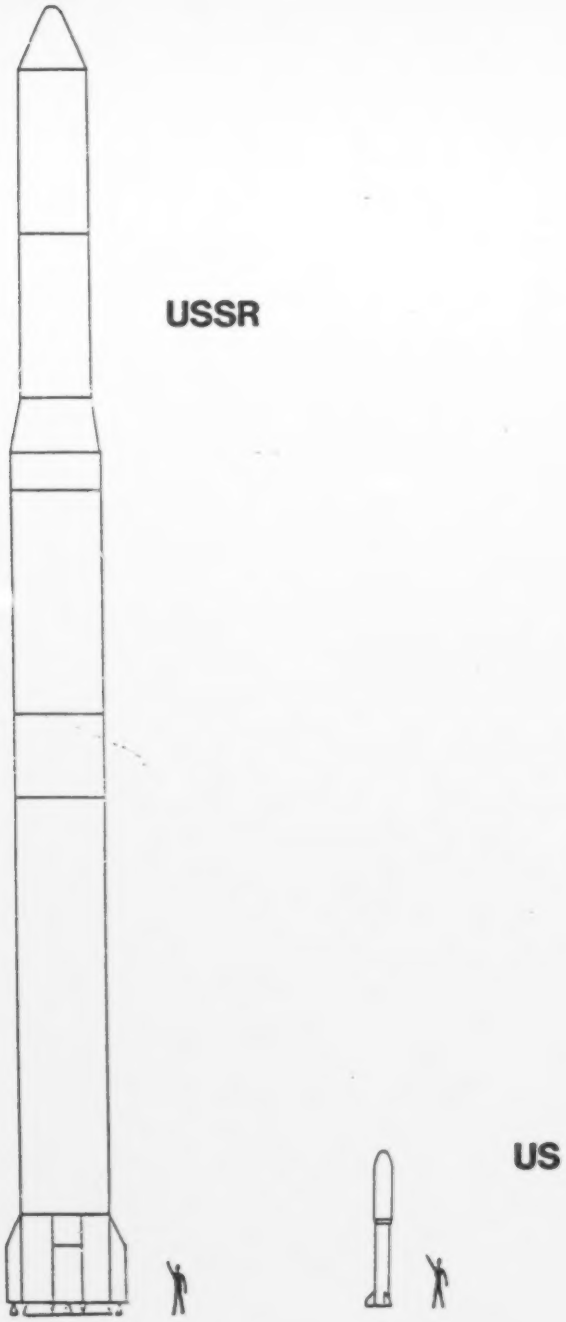
• The Soviet ASAT, which uses fixed launch sites, is a cumbersome and inflexible system in comparison to the mobile, F-15 based U.S. system.

These comparisons lie behind our contention that the United States risks little if both nations' ASAT development programs were to be suspended at this time, while negotiations take place. If, for one reason or another, the United States would find it necessary to resume its development program, it could begin space tests promptly to bring its ASAT system up to operational standards. The Soviet ASAT system, though it is deemed to be operational, only poses a rather clumsy threat to a portion of U.S. space systems, and it has little potential for attacking the warning, communication, and navigation satellites on which U.S. strategic forces depend.

In short, if negotiations fail, or arms control in space were to break down, the United States would not find itself in a disadvantageous position.

FIGURE 5

COMPARISON OF U.S. AND SOVIET ASATS



3. A TREATY LIMITING ASAT WEAPONS

The full text of the treaty put forward here is to be found in Appendix I. Here we shall summarize the goals this treaty sets out to achieve. The differences between our proposal and the 1981 Soviet draft treaty are discussed briefly here, and are analyzed more fully in Section 7.

The proposed treaty has three essential ingredients:

• The signatories would undertake not to destroy, damage, render inoperable or change the flight trajectories of space objects.[17]

• The signatories would undertake not to test in space or against space objects weapons for destroying, damaging, rendering inoperable, or changing the flight trajectories of space objects. Furthermore, the signatories would undertake not to place such weapons in orbit or to station them on celestial bodies or in outer space in any other manner.

• Compliance would be verified by national technical means, enhanced by cooperative measures and buttressed by collateral constraints on other space activities to prevent circumvention of the treaty's provisions.

The treaty proposed here formulates restrictions and prohibitions in general terms. Excessive detail in an arms control accord may inadvertently leave loopholes and convey the impression that activities and weapons not explicitly prohibited are therefore permitted. A treaty weighted down with excessive detail may also prove inflexible in coping with new circumstances, and unanticipated technological developments. Our purpose in presenting general treaty provisions here is to provide a focus for discussion of feasible and desirable restrictions on ASAT weapons. In actual bilateral negotiations, the U.S. and the Soviet Union could incorporate more detailed language into the final treaty text that reflects the best advice and wisdom that consultations within each government would provide.

The text put forward here is for a bilateral treaty. However, once agreement between the U.S. and Soviet Union is reached, a multilateral accord open to all nations would be desirable.

We note that our proposal is not the most comprehensive limitation on space weapons possible, for a treaty could also forbid any possession of such weapons, and require that those already constructed be dismantled or destroyed. Such a comprehensive ban is what the United States evidently sought in the negotiations of 1978-1979.

There is much to be said in favor of such a comprehensive ban, but it also

poses formidable verification problems that could only be resolved by protracted negotiations. The major difficulty in a ban on possession would probably come from the U.S. F-15/ASAT, which is small (see Fig. 3). Intrusive on-site inspection would be required to verify that it is not deployed unless the Soviet Union were to be satisfied that they could acquire this knowledge by other means. While the large size (see Fig. 2) of the Soviet ASAT would make the dismantling of the launchers used in past tests readily observable, it is not clear whether other launchers used in the Soviet space program could substitute for this purpose.

To avert further arms competition in outer space as promptly as possible, a ban on further tests in space of ASAT weapons must take priority, and the proposed treaty addresses itself to this urgent objective. Subsequent negotiations that face the knotty problems of verifying a more comprehensive ASAT ban could then be pursued in an atmosphere free of the tensions that would be created by a simultaneous competition in space weaponry. For that reason, the draft treaty obligates the parties (Article V) to begin active negotiations towards more comprehensive restrictions on space weapons as soon as the test ban is in place.

In contrast to the 1981 Soviet draft treaty, which only speaks of weapons in orbit, the treaty proposed here does not allow the use or testing of ASAT weapons whether they are ground- or space-based. Furthermore, our proposed treaty forbids the parties from destroying any space objects (including one's own), whereas the Soviet draft only forbids attacks on space objects of other states. Indeed, the Soviet draft treaty does not appear to limit further testing or development of the current Soviet or U.S. ASAT systems. In space tests, the Soviet interceptor goes into earth orbit before attacking its target. But it may well be able to attack satellites by direct ascent from the ground, or after only a partial earth orbit, and thus it may elude a ban on weapons "placed in orbit." The U.S. ASAT system uses a direct-ascent interceptor and never goes into earth orbit.

A ban on the use and testing in space of ASAT weapons cannot by itself protect satellites. Nevertheless, the ban on testing would provide a severe impediment to the further development of ever more capable ASAT weapons. For the foreseeable future the military and civilian branches of the United States government are likely to remain at least as vitally dependent on satellites as they are already. It is therefore in the long-term security interest of the United States to enhance the survival of its space assets as much as possible, and to achieve this goal with as little friction and cost as it can.

4. THE RELATIONSHIP BETWEEN ASAT AND ABM

Two aspects of the relationship between anti-satellite weapons and ballistic missile defense are of relevance here. First, what restrictions does the SALT I ABM Treaty of 1972 impose on the evolution of technologies that have an ASAT or ABM potential? Second, what is the relationship between the technologies themselves?

It has always been the position of the United States that the ABM Treaty forbids the development, testing and deployment of ABM systems, or their components, except for one system with specified equipment deployed at each nation's capital, and one system deployed in the vicinity of one ICBM field in each country. (The 1974 Protocol reduced this to one system for each side.) The most recent enunciation of this position is to be found in the President's 1984 Fiscal Year Arms Control Impact Statement,[18] which appeared in April 1983, and contains the following statements:

(a) "The ABM Treaty bans the development, testing and deployment of all ABM systems and components that are sea-based, air-based, space-based, or mobile land-based."

(b) "The ABM Treaty prohibition on development, testing and deployment of space-based ABM systems, or components for such systems, applies to directed energy [lasers and particle beams] technology (or any technology) used for this purpose. Thus, when such directed energy programs enter the field testing phase they become constrained by these ABM Treaty obligations."

(c) "The ballistic missile defense potential of future directed energy weapons could eventually create a conflict with the obligations assumed by the U.S. under the provisions of the ABM Treaty."

(d) "With regard to directed energy systems in an ASAT role, only the actual use of systems to interfere with national technical means used to verify compliance with strategic arms control agreements—as opposed to development, testing, or deployment of systems that could be used in such roles—is prohibited under the provisions of the ABM Treaty and the SALT I Interim Agreement and Article XV of the unratified SALT II Agreement."

In short, the ABM Treaty places severe restrictions on any weapons program that is considered to have an ABM role, whatever its physical principles or technology. On the other hand, the treaty has only a minimal impact on ASAT programs, because it only forbids interference with satellites that are used to verify strategic arms control accords.

The lack of stronger restrictions on ASATs provides a possible loophole in the ABM Treaty, since it allows claims that a weapons system under development is intended to be an ASAT when the real objective is ballistic missile defense. Satellites are much more fragile than missiles, and since their time in space is measured in months or years, instead of minutes, they are also far easier to target. As a result, virtually any putative BMD system will be an effective ASAT long before it achieves any significant ABM capability, and the claim that it is really only an ASAT may be difficult to refute for many years. By the same token, a program that really is intended only to achieve an ASAT capability may be perceived as a nascent BMD by the other side.

That these are not just academic concerns is illustrated by the U.S. ASAT. The Miniature Homing Vehicle exploits a technology first developed by the U.S. Army for its Homing Overlay project, which explores the feasibility of intercepting ICBMs in mid-course as the second tier of a comprehensive BMD system.[19]

To summarize, the deployment of ASATs could trigger buildups of offensive missiles, which is precisely what the ABM Treaty was designed to prevent.

5. THE ASAT THREAT WITH AND WITHOUT A TREATY

The value of a ban on ASAT space tests is best measured by looking ahead to the variety of ASAT threats that can be expected in the next five to ten years if there are no further restraints on weapons competition in outer space. In that period the total number of American satellites will increase to about 100, with approximately one-third of these in low earth orbits, about one-fifth in semi-synchronous orbits, and about one-third in geosynchronous orbits. The others will be in highly-elliptical orbits that may dip as low as several hundred miles, but may also rise as high as geosynchronous orbits.

If the Soviets are free to continue ASAT development, we may anticipate the following course of space weapons competition. The first Soviet move might be to improve their current interceptor to reach higher altitudes and defeat potential U.S. satellite defense measures, such as radar jammers, decoys, and evasion. Tests of the current Soviet interceptor up to geosynchronous orbits might be feasible within relatively few years, if the Soviets set themselves to it. This would mean matching the interceptor to a new booster, such as the liquid-fueled PROTON or A-2 rockets used to place the Salyut and Soyuz space vehicles into orbit. The whole system would require testing against space targets to confirm that it worked, and the long launch preparations needed for such massive boosters would make this a very cumbersome ASAT.

Alternatively, the Soviets could pursue a more promising ASAT development program along one or more of at least three paths: a more agile miniature ASAT interceptor, such as the U.S. is developing, which could reach all altitudes with smaller boosters; a more exotic orbiting laser ASAT; or space mines. A space mine is a small satellite that carries an explosive charge and is placed in an orbit that closely follows its potential target. It could then be commanded to destroy instantly the satellite it has accompanied for weeks or months. Unless negotiated restrictions are placed on ASATs, it is very likely that space mines will soon pose a critical threat to satellite systems in conventional war or at the outbreak of nuclear war.

Debate persists over the feasibility and cost of space-based lasers, but there is no question that both sides are vigorously developing them. According to Air Force Chief of Research and Development, General Kelley Burke, the Soviets are believed capable of launching a laser ASAT of limited effectiveness within five years, and a more effective system perhaps in the 1990s. In keeping with their accustomed practice, the Soviets may well develop and deploy a mix of ASAT weapons, each posing a different threat to U.S. satellites: improved ground-based interceptors and lasers for lower orbit attacks, space-based lasers for higher orbits, and space mines for geosynchronous attacks. Along the way, the number of launch sites would be increased, inventories of ready-to-fire ASAT weapons

38-036 O - 84 - 76

would multiply, and all U.S. satellites would become progressively more vulnerable to attack.

The U.S. has already mapped out its initial moves in this competition. In the beginning, it will incorporate defenses on satellites, and deploy the sophisticated F-15 ASAT MHV interceptor described in Section 2. Ground- and air-based lasers would provide additional ASAT capability against low-orbit satellites while helping to solve technical problems in the development of space-based lasers. A "defensive" space-based laser weapon would be the next step—an ASAT deployed to attack Soviet ASATs. At this stage, the scene might recall the battleship competitions of an earlier era, as each side strives for the competitive edge of just a bit more firepower, longer range, thicker armor, and larger fleets.

Under such unrestrained ASAT competition, the advantage will almost certainly go to the offense. A duel between a sophisticated ASAT weapon devised for the sole task of killing, and a satellite built for other purposes and only incidentally equipped to defend itself, will always be a mismatch. Moreover, U.S. satellites are designed for lifetimes of five to ten years, so the defenses they carry with them into space on the day of launch stand a good chance of being nullified by a rapidly-changing ASAT environment. Soviet satellites have much shorter lifetimes, are therefore more frequently replaced, and could be more readily modified to counter U.S. ASAT developments.

In confrontations in a world filled with ASATs, fear of a preemptive strike will run high, and the very process of unlimbering ASATs for possible use would drive tensions higher. Since attacks on satellites would be a possible opening step in war, even inadvertent events in space may be mistaken as a signal that war has begun. The sheer multiplicity of ASATs would also raise the likelihood of such an inadvertent occurrence. Such events have happened. For example, in 1975 there was concern that U.S. early-warning satellites had been attacked by Soviet infrared lasers; later it was established that these satellites had only observed infrared radiation from a Soviet natural gas pipeline fire.

Were a satisfactory ASAT arms control agreement in force, the future would look quite different. As matters stand now, only a fraction of U.S. satellites are exposed to the rudimentary Soviet ASAT system. Under a general ban on tests of ASAT systems in space, Soviet efforts to improve their current interceptor or to devise a new one should be blunted. Tests or use of lasers or high-powered transmitters to damage satellite sensors or to burn out satellite receivers would be banned. In contrast, under unrestrained ASAT competition, protecting American satellites through hardening, maneuvering, deception, and so forth, against ever more sophisticated and nimble Soviet ASATs, will become untenable. Exotic laser ASATs may well prove infeasible in the near future, but the Soviets would still be free to duplicate the U.S. miniature ASAT interceptor and threaten American satellites at all altitudes. Five to ten years from now, after successive rounds of unrestrained competition, the security of U.S. satellites, and thereby of the

United States, will have been seriously impaired, despite greatly increased expenditures. In sum, the contrast between a future with ASAT arms control, and one without, is stark.

It is to be hoped that an initial ban on ASAT tests could soon be augmented by a wider agreement to dismantle ASATs. Until such time as a comprehensive ban on possession of ASAT systems could be negotiated, there would still be a limited Soviet ASAT threat to those U.S. satellites within reach of the current Soviet interceptor. It would be doing arms control a disservice to claim that ASAT arms control alone could protect all space assets. (By the same token, extravagant claims that acquiring ASAT weapons will solve all our problems are equally mistaken.) What ASAT limitations could do is to make the task of protecting satellites less difficult, more reliable, and thus enhance confidence in the survival of satellites vital to U.S. security. ASAT arms control, then, serves American security interests by being an indispensable adjunct to, and not a replacement for, U.S. programs to diversify its satellite functions and harden its satellites against attacks.

Under a general ban on space tests of ASATs, the U.S. would also have to forego tests in space of the ASAT interceptor it is now developing. The U.S. reportedly is set to begin tests of its interceptor in space and against space targets within the year. If an ASAT accord were reached promptly, or if the U.S. offered to improve the prospects for successful negotiations by a voluntary test moratorium, the outcome might be that the U.S. would have no test experience with its ASAT in space, while the Soviets would have conducted some twenty tests over the past fifteen years. But there are compensations that must be weighed. The Soviet's ASAT test program has not been a great success (see Section 3). The U.S. has already accumulated a body of test and engineering experience just short of tests in space, so it would not be left with a blank slate. Furthermore, unless the U.S. closes off further ASAT testing soon, it risks exposing all its vital satellites to possible improvements in the Soviet ASAT system, improvements that might require years of American effort and billions of dollars to then offset.

In agreeing not to use ASATs, the U.S. would also forego one of the stated purposes for buying its ASAT system: attacking Soviet satellites that can be used to target U.S. military forces. The principal satellites of concern are the Soviet Radar Ocean Reconnaissance Satellites (RORSATs) and Electronic Ocean Reconnaissance Satellites (EORSATs) that can locate ships at sea. It is important to weigh whether this limitation would significantly compromise American security.

To begin with, giving up ASATs does not mean giving up all means of countering Soviet satellite capability. Nothing in the treaty proposed here would prevent U.S. forces from using other countermeasures to deceive or confuse Soviet satellites, such as spoofings, decoys, camouflage, electronic countermeasures, etc.

Secondly, ASATs may not in fact provide much protection for U.S. military forces. The Soviets have a variety of sea-based and airborne reconnaissance and targeting systems, so shooting down Soviet satellites would not eliminate the threat. Any U.S. forces designed to operate along the periphery of the Soviet Union, where U.S. alliance obligations are, must be equipped with an array of countermeasures and defenses in any case. Thirdly, if the Soviets are the ones to initiate hostilities, they will have been able to gather and pass along satellite information needed to target U.S. forces before conflict starts. The U.S. would be unlikely to shoot down Soviet satellites preemptively just on suspicion of Soviet intentions; doing so would certainly provoke hostilities. And for some time after hostilities break out, the Soviets may also be able to launch new satellites to replace those destroyed by a U.S. ASAT; American military forces would again have to be prepared to fend for themselves in the face of threatening Soviet satellites.

Finally, U.S. military forces (with the exception of submarines) cannot count indefinitely upon concealment for their survival. They must be prepared sooner or later to withstand the brunt of Soviet forces. A U.S. ASAT system cannot protect an aircraft carrier, once it is discovered, by shooting down Soviet anti-ship missiles or intercepting torpedoes. But the U.S. ASAT program diverts resources and funds from other defense programs vital to our forces. According to the General Accounting Office, the U.S. ASAT program is already slated to cost $3.6 billion; the GAO argues that the cost could well rise to "tens of billions." Even at $3.6 billion, the "opportunity cost" of the ASAT system already equals one Nimitz-class nuclear-powered aircraft carrier. Where such trade-offs are involved, an ASAT system is not an incidental option, but potentially a major drain upon overall U.S. military preparedness.

The most important concern for the U.S. is to ensure that its satellites can carry out their tasks, even in crisis or conflict. Using an ASAT to shoot down Soviet satellites would not protect or restore U.S. satellites. It is occasionally argued, as justification for the U.S. ASAT program, that our own ASAT can deter Soviet ASAT attacks by the threat of a tit-for-tat response. Given the greater American dependence upon satellites, the U.S. might in fact only make its situation worse by such tit-for-tat exchange. The best "deterrent" to Soviet ASAT attacks is Soviet awareness that U.S. satellite functions are diversified and hardened, and adequately supplemented by non-satellite systems, so that an attack on satellites would not succeed in crippling the overall U.S. military capability. An American ASAT system contributes nothing to this "deterrent"; it promises only to divert funds from the countermeasures that would genuinely provide such security.

6. VERIFICATION AND RESIDUAL RISKS

It has been argued that ASAT arms control poses daunting, perhaps even insuperable, verification problems, more so than any other area of arms control. One reason offered for this is that space satellites are so few in number, and their unique capabilities so difficult to duplicate with ground-based alternatives, that even a few ASAT weapons covertly acquired in violation of an agreement could reward the cheater with significant military advantage in a conflict. It is additionally argued that any limitations upon weapons or space programs that would be comprehensive enough to close off such cheating would necessarily be so stringent that they would preclude many civilian uses of outer space. As an illustration, the Soviet Progrez resupply vehicles, used with the Salyut program, obviously have features in common with ASAT interceptors: they can be launched to the vicinity of an orbiting satellite, maneuvered alongside, and brought into contact. Yet banning them, or limiting all such maneuvering space vehicles to prevent them from being configured as ASAT weapons would impair not only the Salyut program but the U.S. Space Shuttle as well. The problems are multiplied if we also consider the ASAT potential of other weapons not specifically designed as ASATs, such as ground-based ABM interceptor missiles, or nuclear-tipped ICBMs, or exotic directed-energy air defenses.

These arguments point to genuine concerns the U.S. ought to have about the survivability of its satellites. At the same time, these arguments assume that the future is dictated by past errors. In the past, the U.S. coped with limited budgets and high launching costs (hundreds, even thousands of dollars per pound to place objects in orbit) by relying on relatively few, long-lived, equipment-crammed satellites to perform vital military tasks. Little effort was made to incorporate survivability measures or to diversify functions. Because of their design and budgeting constraints, U.S. satellites are even vulnerable to primitive ASAT weapons.

But with or without ASAT arms control, the U.S. cannot go on like this. Nor does it intend to. A Presidential Directive in May 1978 ordered that all future U.S. military satellites be equipped with survivability measures and devices for detecting ASAT attacks. Some satellites probably cannot be protected from attacks at any affordable cost (e.g., large and fragile low-orbit satellites); and some attacks may work against almost any satellite (e.g., nuclear warheads detonated near a satellite). The best approach to reducing the risk is to move to a larger number of simpler, more easily replaced satellites that are more readily confused with decoys. Yet even this technique will succeed only if the Soviets are prevented from developing a cheap, nimble ASAT system capable of promptly attacking great numbers of satellites. It is precisely this sort of development that an ASAT arms control agreement should prevent.

There are several verification tasks that must be tackled under a general ban

on ASAT weapons tests and use. The U.S. would have to confirm that the existing Soviet ASAT interceptor was not being tested in space; that no new ASAT weapons were being devised and tested in space or against space targets, including such new exotic ASATs as ground- or air-based lasers that could be aimed at low-orbit satellites; that weapons originally designed and deployed for other missions were not being tested in an ASAT mode and that non-weapon space vehicles and programs were not posing significant ASAT threats.

The U.S. already has a diverse array of intelligence and space surveillance facilities for keeping track of Soviet activities, and this array is being expanded. NORAD's Space Object Catalogue is constantly being updated to record the identity and current orbits of all space objects (several thousand in all, of which several hundred are active or defunct satellites). NORAD's space tracking radar network has recently been upgraded to provide greater tracking accuracy, and gaps in the network have been closed by installing and improving radars in the Pacific. The GEODSS (Ground-based Electro-Optical Deep Space Surveillance) system, when completed in 1987, will augment ground radars and provide precise, highly-detailed optical and orbital signature data on man-made objects approximately 3000 miles from earth and beyond. Upgraded radars in the United States, Turkey, and Kwajalein will provide additional tracking of objects in geosynchronous orbits.

Other electronic and optical sensors deployed around and over the Soviet Union add to U.S. ability to detect and classify Soviet missile and space launches. The potential for monitoring activities **in** outer space **from** space must also be considered. The recent demonstration of what is possible, in inspecting damaged and missing thermal tiles on the first Space Shuttle flight in April 1981, hints at what might be routinely feasible. On occasion, critiques of space verification capabilities tend to match only **current** monitoring capacities against **future** conceivable but nonexistent ASAT weapons, and not surprisingly, these comparisons come to pessimistic conclusions. More imaginative evaluations should consider what we could now do but have not funded, as well as potential innovations in monitoring capabilities. In particular, under a treaty-restricted regime it would become worthwhile to make specialized observation systems to monitor the infrared emission from Soviet satellites in order to determine whether they were being heated by ground-based or airborne lasers, to provide close-in photographs of maneuverable space objects, and the like.

The effectiveness of all the monitoring facilities would be enhanced under an arms control agreement by provisions, such as those included in prior accords, prohibiting interference with national technical means of verification and deliberate concealment that impedes verification. Since the Soviets have already agreed in principle that arms control accords may include cooperative measures contributing to the effectiveness of verification by national technical means (in the SALT II Joint Statement of Principles), these too should be exploited to improve confidence in verification.

on ASAT weapons tests and use. The U.S. would have to confirm that the existing Soviet ASAT interceptor was not being tested in space; that no new ASAT weapons were being devised and tested in space or against space targets, including such new exotic ASATs as ground- or air-based lasers that could be aimed at low-orbit satellites; that weapons originally designed and deployed for other missions were not being tested in an ASAT mode and that non-weapon space vehicles and programs were not posing significant ASAT threats.

The U.S. already has a diverse array of intelligence and space surveillance facilities for keeping track of Soviet activities, and this array is being expanded. NORAD's Space Object Catalogue is constantly being updated to record the identity and current orbits of all space objects (several thousand in all, of which several hundred are active or defunct satellites). NORAD's space tracking radar network has recently been upgraded to provide greater tracking accuracy, and gaps in the network have been closed by installing and improving radars in the Pacific. The GEODSS (Ground-based Electro-Optical Deep Space Surveillance) system, when completed in 1987, will augment ground radars and provide precise, highly-detailed optical and orbital signature data on man-made objects approximately 3000 miles from earth and beyond. Upgraded radars in the United States, Turkey, and Kwajalein will provide additional tracking of objects in geosynchronous orbits.

Other electronic and optical sensors deployed around and over the Soviet Union add to U.S. ability to detect and classify Soviet missile and space launches. The potential for monitoring activities **in** outer space **from** space must also be considered. The recent demonstration of what is possible, in inspecting damaged and missing thermal tiles on the first Space Shuttle flight in April 1981, hints at what might be routinely feasible. On occasion, critiques of space verification capabilities tend to match only **current** monitoring capacities against **future** conceivable but nonexistent ASAT weapons, and not surprisingly, these comparisons come to pessimistic conclusions. More imaginative evaluations should consider what we could now do but have not funded, as well as potential innovations in monitoring capabilities. In particular, under a treaty-restricted regime it would become worthwhile to make specialized observation systems to monitor the infrared emission from Soviet satellites in order to determine whether they were being heated by ground-based or airborne lasers, to provide close-in photographs of maneuverable space objects, and the like.

The effectiveness of all the monitoring facilities would be enhanced under an arms control agreement by provisions, such as those included in prior accords, prohibiting interference with national technical means of verification and deliberate concealment that impedes verification. Since the Soviets have already agreed in principle that arms control accords may include cooperative measures contributing to the effectiveness of verification by national technical means (in the SALT II Joint Statement of Principles), these too should be exploited to improve confidence in verification.

The U.S. already has long monitoring experience with tests of the current Soviet ASAT interceptor, going back 15 years. Covert tests of that weapon would be rather risky for the Soviets. Conceivably, the Soviets might try to test their current ASAT covertly in some radically different manner that expanded its capabilities, e.g., on a new booster capable of intercepts significantly higher than its present ceiling. This would not be a "nimble" threat, even in the unlikely event that cheating succeeded. The booster required to loft the Soviet's bulky ASAT up to geosynchronous altitudes would have to be comparable to the large U.S. Saturn IB or the Soviet PROTON booster, massive rockets with long preparation times, whose launches would be unmistakable.

More likely, if the Soviets hoped to expand their ASAT capability covertly, they would attempt an entirely new weapon, such as a miniature homing ASAT, or a more exotic laser ASAT, or space mines. Until such time as ASATs are banned altogether, neither side would be violating the limitations if they devised such systems on the ground; they would be banned from testing them in space or against space objects.

But the technological challenges in building an effective space-based laser ASAT are formidable, even if unrestricted testing in space were permitted, and doing it all covertly would certainly be a protracted, highly risky task. To prevent the Soviets from testing ASATs in space under the pretense of developing, for instance, a space-based laser anti-aircraft defense system, our draft treaty also bans space weapons for damaging or destroying objects in the atmosphere or on the ground. This prohibition would also reinforce existing limitations on space weapons in the 1967 Outer Space Treaty and the 1972 ABM Treaty.

Ground- or air-based laser ASATs are far easier to construct than space-based lasers, but it is not clear that they offer any advantages over current ASATs. Such lasers could impair unprotected satellite sensors at high altitudes, but could only destroy satellites in low orbits. Whether Soviet technology is sufficiently far advanced to make a miniature homing ASAT feasible in the near term is not clear. In all these new ASATs, however, very high accuracies in homing or aiming would be necessary, and these would be difficult to confirm without actual tests against space targets. Such tests would leave a host of telltale signs: launch of the ASAT itself; a large flow of data from the test vehicles that the Soviets would have to transmit; damage to the target that causes it to fragment or tumble; intense heating that can be detected by infrared sensors; and displacement of the target's orbit. While the Soviets were pressing ahead with such innovations, there would, of course, be a parallel expansion and evolution of U.S. monitoring facilities, which would further facilitate the detection of cheating.

Space mines placed in orbit near targets and detonated only when conflict begins are another problem. They seem ingeniously simple. The technology could perhaps be fairly primitive, and if the only tests required were triggering the explosive upon command, they could be amply tested on earth. Nevertheless, if

covertly deployed they might give themselves away or pose only a manageable threat. The orbital paths of satellites are not necessarily stable, especially those of satellites in lower orbits that are subject to atmospheric drag, or that maneuver to perform their missions. Space mines dogging along behind such maneuvering satellites would be bound to raise suspicions, and the mine ceases to be such a simple device if it must be equipped with homing and maneuvering capabilities to keep track of its potential target or be able to close in rapidly on command. At geosynchronous altitudes, where all orbits are more stable, a space mine skulking near its target could still arouse suspicions, since all legitimate satellites are supposed to be registered (under the 1975 Convention on Registration of Objects Launched into Outer Space) and are to maintain minimum separation distances in geosynchronous orbits. Again, a space mine becomes a complex device if it must pretend to be something benign when far away from its target to avoid suspicions, yet can swiftly seek its target upon command.

When it comes to verifying that non-ASAT weapons are not being put to ASAT purposes, long U.S. experience at monitoring the characteristic patterns of Soviet ICBM and ABM tests would also make it risky for the Soviets to test these weapons in an ASAT mode. Of course, even in the absence of tests such weapons would still have to be taken into account as an ASAT threat, since the great kill-distance of nuclear explosions in space could compensate for deficiencies in guidance systems or test experience. But it is also true that present ABM interceptors can reach satellites only in the lowest orbits, and any nuclear explosion in space carries a grave risk of escalation, of damage to "friendly" satellites as well as to the target, and of uncertain Electro-Magnetic Pulse (EMP) effects upon other military and civilian systems on earth. While such residual ASAT threats are less awesome than what unrestricted ASAT competition would produce, they would persist, even if the ability to verify a test ban were perfect. They call for continuing satellite survivability programs as an adjunct to ASAT arms control.

Some non-weapon space vehicles may also have inherent ASAT capability (e.g., resupply vehicles that can home in on other satellites), and the U.S. would want to verify that such vehicles were not being tested in an ASAT mode. The overlap of non-weapon space technology with ASAT missions should not be exaggerated, however. The continuing high cost of launching anything into space will certainly force designers to optimize space vehicles for their specific non-weapon missions, and the result is not likely to be a very agile or capable ASAT. The Soviet's Progrez resupply vehicle, for instance, is obviously designed to deliver the maximum amount of provisions in few trips. Its takeoff weight, fully loaded, is perhaps three times that of the Soviet's own bulky ASAT, and consequently it uses an enormous booster just to reach altitudes of a few hundred miles. Such jury-rigged ASATs are not very good foundations for a weapon system to "sweep the skies," and making vital U.S. satellite functions survivable against such residual threats should be manageable.

Nevertheless, an ASAT arms control agreement could incorporate collateral

constraints on the characteristics and use of non-weapon space technologies. These constraints might include, for instance, limits upon speed of approach in rendezvous maneuvers, or upon power/aperture characteristics of lasers in space. However, it would be premature now to propose a long list to govern future changes in space technology. The treaty proposed here would accomodate such collateral constraints in several ways. Cases that the parties find of immediate concern could be addressed in treaty negotiations and incorporated as additional articles, or perhaps as cooperative measures in test or space-use procedures that aid verification. Limits on future cases involving new technologies would best be addressed on a case-by-case basis in the Standing Consultative Commission, as the specific dimensions of problems and remedies become clear. This approach would raise our confidence that such space vehicles were not being readied as ASATs, while minimizing the impact upon non-weapon space exploration.

A final verification concern is that of "breakout," that is, the possibility that the Soviet Union could assemble a significant ASAT capability by abruptly running a quick set of space tests (and thus abrogating the treaty). At issue here is how close to operational status an ASAT weapon could be brought, if assembled and tested only on the ground or covertly in space as dismantled components—e.g., testing homing sensors for ASAT interceptors on some ostensibly non-weapon space mission. Inconsistencies occasionally crop up in arguments on this matter. On the one hand, it is claimed the Soviets could readily concoct an ASAT system even though space tests were banned; on the other, it is asserted the U.S. could not accept a ban on testing because it would then be unable to confirm that its own ASAT system works. A more balanced viewpoint is in order here.

The U.S. has already conducted enough engineering tests of its own ASAT interceptor to be ready for immediate space tests, so even if a moratorium on tests were agreed upon now, the U.S. would not be without experience. If the ASAT accord banned tests but allowed both sides to keep their present ASAT weapons, then clearly both would have some "breakout" potential. Though the existing Soviet ASAT is a much more tractable problem than what unrestrained ASAT competition would bring, this "breakout" potential would be of some concern for the U.S. A combination of reasonable survivability measures, eroding Soviet confidence in their ASAT in the absence of tests, and further negotiations leading toward complete dismantling of ASATs would address our concerns.

"Breakout" using an entirely new ASAT weapon that had been tested only on the ground or covertly—component by component—in space would be quite risky, technically and politically. In ASAT weapons as in modern weaponry in general, capability and complexity are linked—the more capable a weapon is in coping with a variety of combat requirements, the more complicated it is likely to be, and the more in need of tests that simulate actual engagements. Soviet attempts to conduct realistic full-system ASAT tests in space covertly would confront the whole battery of U.S. intelligence sensors. On the other hand, breaking the ASAT system down into component parts for covert testing, in order

to minimize the chance of detection, entails a risk that the whole system will not work as well operationally as the parts. The Soviets have clearly experienced gaps between plans and performance in space and weapon systems, and even catastrophic shortcomings. Without tests, the Soviets could not confidently predict how soon a new device could be made to work after "breakout" —if at all. An ASAT test ban could serve U.S. interests by exploiting Soviet uncertainties and fear of detection, while leaving the U.S. free to complicate the Soviet's "breakout" task through a variety of satellite defensive measures.

In sum, there are no obvious reasons why an arms control agreement banning space tests and use of ASAT weapons could not be adequately verifiable. There may be some areas of uncertainty, but not so great as to permit the Soviets to pose a significant, unanticipated threat to U.S. security if we take prudent steps towards improving intelligence capabilities and diversifying and protecting vital satellite functions.

7. COMPARISON WITH THE 1981 SOVIET DRAFT TREATY

There are several important contrasts between the treaty proposed here and the provisions of the Soviet Union's draft treaty placed before the U.N.

The first contrast is in comprehensiveness. Article 1 of the Soviet treaty addresses weapons placed in orbit around the earth. Strictly speaking, the Soviet formulation does not appear to limit further tests and development of either the Soviet or U.S. ASAT systems. In space tests, the current Soviet interceptor goes into orbit before attacking its target, but it may well be able to attack satellites by direct ascent or after partial orbit. The U.S. ASAT is a direct-ascent interceptor that does not go into orbit. Hence, both seem to elude a ban on weapons "placed in orbit." Ground-based laser ASATs also elude the Soviet formulation. In contrast, the treaty proposed here prohibits all testing of ASAT weapons in space or against objects in space, whether the ASAT weapon is ground- or space-based. This includes tests against one's own space objects, not (as the Soviet text reads) just those of other parties.

A second contrast concerns Article I of the Soviet draft treaty, which reads, in part, "the parties undertake not to station such weapons in outer space . . . , including on reusable manned space vehicles." Because the U.S. Space Shuttle is the only such vehicle now in use, such specific mention in the Soviet proposal must raise suspicions that the Soviets intend to somehow impair the Shuttle program. This impression was compounded by the fact that the English text of the treaty used by some nations in the U.N. left out the crucial word "on." The draft was therefore understood to include "reusable manned vehicles" among the weapons banned from space. Specific mention of reusable manned vehicles is in fact superfluous and is dropped from our proposed treaty text. Any general obligation not to test or place anti-satellite weapons in space would apply, no matter what launch vehicle happened to be used. The Soviets would be banned from using their current space vehicles, such as Salyut or Progrez, or any future Soviet shuttle, for such purposes. The same constraints would of course apply to the U.S. Space Shuttle.

A third contrast concerns Article 3 of the Soviet draft treaty, which contains a general ban on the use of weapons in outer space. The Soviet version, however, adds a reservation: the satellites of the other side would enjoy protection if they did not violate other restraints in the treaty. Here, and in Article 2, the Soviet draft seems to attempt a general limitation on satellites, rather than upon anti-satellite weapons. Indeed, the Soviet formulation gives an impression of legitimizing attacks upon satellites engaged in certain acts, rather than forbiding such attacks.

There are two underlying issues here: first, what rights would one side retain if the other tested or used an anti-satellite weapon in violation of the treaty; and

second, what would the sides be permitted if a third nation tested or used an ASAT weapon in space? On the first point, obviously any violation of ASAT limits by the U.S. or the Soviet Union would be a grave act, and the other side would be justified in exercising rights of withdrawal from the treaty. Such provisions for withdrawal, customary in previous arms control treaties, are adequate to cope with this issue when buttressed by prudent satellite survivability measures.

The second point underscores the importance of eventually transforming a bilateral ASAT treaty into a multilateral accord. It would be regrettable indeed if some third nation undercut superpower limitations upon space arms competition by launching its own ASAT. Still, a bilateral ASAT treaty between the superpowers should not contain provisions that appear to sanction attacks upon the space objects of third nations. If third parties disrupt the agreement reached by the superpowers, the first recourse for the U.S. and Soviet Union should be consultation, as is provided for in the attached treaty. The final recourse would be inherent right of withdrawal where extraordinary events jeopardize supreme national interests.

Finally, the introduction of the Soviet draft proposal in the U.N. General Assembly raises the question of whether the best prospect for space arms control is through multilateral or bilateral negotiations. A superpower arms competition in space would certainly be a matter of global concern. Objects circling the earth in outer space can come within a hundred miles or so of every point on the globe, of every nation on earth. Outer space can be used in a host of ways to yield security and prosperity for all nations. It is therefore desirable that any arms control restraints on weapons in outer space be broadly affirmed and respected by all nations.

At the moment, however, only the Soviet Union and the U.S. have ASAT programs. Since their accession is indispensable to any meaningful limitations on space weapons, and since their ASAT programs are proceeding apace, it is most important that the superpowers begin direct negotiations, unimpeded by the delays that unavoidably arise in wider multilateral forums.

The best course, therefore, would be for the U.S. and the Soviet Union to begin direct negotiations on bilateral restraints, keeping in mind the desirability of eventually incorporating their accord into a multilateral treaty appropriate for signature by all nations.

17. The term "space objects" would correspond to "objects launched into outer space" in the Outer Space Treaty of 1967. Such objects include not only all functioning objects commonly called "satellites," but also all objects on interplanetary flights as well as all man-made pieces of debris. The term does **not** include nuclear missile warheads on ballistic trajectories, even though these pass through space. Hence, an ASAT treaty along these lines would not alter the rights or obligations of the 1972 ABM Treaty which covers weapons used against ballistic missiles.

Appendix I

A TREATY LIMITING ANTI-SATELLITE WEAPONS

Preamble

ARTICLE I

Each Party undertakes not to destroy, damage, render inoperable or change the flight trajectory of space objects of other States.

ARTICLE II

1. Each Party undertakes not to place in orbit around the earth weapons for destroying, damaging, rendering inoperable, or changing the flight trajectory of space objects, or for damaging objects in the atmosphere or on the ground.

2. Each Party undertakes not to install such weapons on celestial bodies, or station such weapons in outer space in any other manner.

3. Each Party undertakes not to test such weapons in space or against space objects.

ARTICLE III

1. For the purpose of providing assurance of compliance with the provisions of this treaty, each Party shall use national technical means of verification at its disposal in a manner consistent with generally recognized principles of international law.

2. Verification by national technical means shall be supplemented, as appropriate, by such cooperative measures for contributing to the effectiveness of verification by national technical means as the Parties shall agree upon in the Standing Consultative Commission.

3. Each Party undertakes not to interfere with the national technical means of verification of the other Party operating in accordance with paragraph 1 of this Article.

4. Each Party undertakes not to use deliberate concealment measures which impede verification by national technical means of compliance with this treaty.

ARTICLE VII

Each party undertakes not to assume any international obligation which would conflict with this treaty.

ARTICLE VIII

1. Each Party may propose amendments to this treaty.

2. Agreed amendments shall enter into force in accordance with the procedures governing the entry into force of this treaty.

ARTICLE IX

This treaty shall be of unlimited duration.

ARTICLE X

Each Party shall, in exercising its national sovereignty, have the right to withdraw from this treaty if it decides that extraordinary events related to the subject matter of this treaty have jeopardized its supreme interests. It shall give notice of its decisions to the other Party six months prior to withdrawal from the treaty. Such notice shall include a statement of the extraordinary events the notifying Party regards as having jeopardized its supreme interests.

ARTICLE XI

1. This treaty shall be subject to ratification in accordance with the constitutional procedures of each Party.

2. This treaty shall enter into force on the day of the exchange of instruments of ratification.

ARTICLE XII

1. Done in two copies, each in the English and Russian languages, both texts being equally authentic.

2. This treaty shall be registered pursuant to Article 102 of the Charter of the United Nations.

38-036 O - 84 - 77

ARTICLE IV

1. To promote the objectives and implementation of the provisions of this treaty, the Parties shall use the Standing Consultative Commission, established by the Memorandum of Understanding Between the Government of the United States of America and the Government of the Union of Soviet Socialist Republics regarding the Establishment of a Standing Consultative Commission of December 21, 1972.

2. Within the framework of the Standing Consultative Commission, with respect to this treaty, the Parties will:

a) consider questions concerning compliance with the obligations assumed and related situations which may be considered ambiguous;

b) provide on a voluntary basis such information as either Party considers necessary to assure confidence in compliance with the obligations assumed;

c) consider questions involving unintended interference with national technical means of verification, and questions involving unintended impeding of verification by national technical means of compliance with the provisions of this treaty;

d) consider, as appropriate, cooperative measures contributing to the effectiveness of verification by national technical means;

e) consider possible changes in the strategic situation which have a bearing on the provisions of this treaty, including the activities of other States;

f) consider, as appropriate, possible proposals for further increasing the viability of this treaty, including proposals for amendments in accordance with the provisions of this treaty.

ARTICLE V

The Parties undertake to begin, promptly after the entry into force of this treaty, active negotiations with the objective of achieving, as soon as possible, agreement on further measures for the limitation and reduction of weapons subject to limitation in Article II of this treaty.

ARTICLE VI

In order to ensure the viability and effectiveness of this treaty, each Party undertakes not to circumvent the provisions of this treaty, through any other State or States, in any other manner.

Appendix II

ANSWERS TO WRITTEN QUESTIONS POSED BY SENATE FOREIGN RELATIONS COMMITTEE TO RICHARD GARWIN, NOEL GAYLER, AND KURT GOTTFRIED ON May 18, 1983

June 3, 1983

QUESTION 1: What do you regard as the most destabilizing developments in current and future space programs?

Response: In our view the most destabilizing aspects of current and future US and Soviet space programs are:

a) The continuing testing of the Soviet ASAT;
b) the upcoming tests of the US F-15 ASAT;
c) the absence of any negotiations to limit the further growth of ASAT capabilities; and
d) President Reagan's speech of March 23, 1983, setting a US course towards a perfect defense against all nuclear-armed missiles (as interpreted on national television by Secretary of Defense Weinberger on March 27, 1983).

Taken together, these actions and policies are:

i) planting the seeds for a capacity that will, if allowed to grow, threaten our space-borne warning systems with preemptive attack; and

ii) seriously imperil the ABM treaty, and with it our confidence that our retaliatory forces continue to retain the ability to penetrate Soviet defenses.

Even though there is no scientific justification for holding out hope for a leak-proof space-based defense against nuclear weapons, the quest for such a defense will, even if futile, have destabilizing consequences. In particular, the prospect of a space-based BMD system is certain to spawn the development of space mines by the adversary, which will hound the BMD platforms to assure penetration of ICBMs. Space mines will be developed even if, as is most probable, no BMD capability is ever achieved, and these mines will then threaten all objects in space, whether they carry weapons or not. This could lead to war in space as a prelude to war on earth.

QUESTION 2: In his March 23 speech, President Reagan stated that if laser defense was "paired with offensive systems, they can be viewed as fostering an aggressive policy."

a) Do you agree with this assessment?
b) If so why? If not, why not?
c) Some have argued that if we can reduce offensive weapons to the point that they no longer appear offensive then there would be no need for a space-based BMD system. Do you agree?

Response:

a) We agree that an effective defense against nuclear weapons, when paired

with the existence of offensive systems, would "support an aggressive policy." But as we make clear in our responses to Questions 9 & 10, we do not accept the underlying assumption in the President's statement, to wit, that an effective defense against missile-borne nuclear warheads can be built.

b) It can support a coercive policy. In fact, held by one side, such capabilities would allow world domination. Paradoxically, if offensive and perfect defensive weapons were available to both sides (leaving aside the rest of the world for the moment), there would be no feeling of serenity, since it would be quite obvious that the effectiveness of a defense might be destroyed catastrophically by sabotage, deception, or the like.

c) We doubt that either the Soviet Union or the United States is likely to give up offensive weapons and the insurance of deterrence by threat of retaliation. Yes, we suspect that it would be easier to negotiate away offensive weapons than to build an effective space-based BMD system.

QUESTION 3: Some government officials contend that any Soviet missile can serve as an ASAT launcher. Accordingly, it is argued, verification of an ASAT ban could be difficult, if not impossible. Do you agree with this view?

Response: In all 20 reported tests of their ASAT interceptor over the past 15 years, the Soviets have used only one launch booster, a missile based on the old SS-9 "heavy" ICBM. Therefore, the Soviets lack ASAT experience with any other missile. Anyone who imagines that "any Soviet missile can serve as an ASAT launcher" displays a lack of awareness of the difficulties that habitually plague space hardware programs, and the Soviet ASAT program in particular. If the Soviets sought to use a different booster, they would confront several obstacles. First, if the interceptor itself has been specially designed to fit onto the SS-9 missile, it would have to be redesigned to fit a new booster, and the new configuration would require space tests to confirm that the entire system worked properly in its new form. Such tests would be visible to U.S. surveillance systems. Secondly, the bulk of Soviet space launch boosters and operational ICBMs have launch- and payload-weights no greater than the SS-9, and the Soviets would gain little by putting their ASAT on a different missile that was only comparable or inferior to the current booster. Thirdly, the SS-9 itself has been phased out and replaced by the SS-18. If the Soviets sought to put their ASAT interceptor on a silo-based SS-18, then the silo too must be designed to accommodate the extra length and special launch-preparation requirements of the interceptor. Major modifications to operational silos, if they were required, would be monitored by U.S. intelligence systems, as could space test of the new SS-18/ASAT configuration.

Finally, there are Soviet boosters that are larger than the SS-9, such as those used for the Soyuz and Salyut programs, and these in principle could carry the Soviet ASAT to higher altitudes. However, attacking satellites at higher altitudes places greater demands upon an interceptor, e.g., greater homing range, greater guidance accuracy, greater maneuvering power. Such improvements in an interceptor would also require space tests to confirm. So, even if the Soviet interceptor could be mounted on a different booster, that alone could not increase the threat it

poses, as long as further space tests are banned.

A prompt ban on further ASAT space tests would serve U.S. interests by inhibiting any such improvements to the current Soviet ASAT system.

QUESTION 4: The Soviets have tabled a draft treaty that would ban all weapons from space. This treaty would apparently allow the Soviet Union to retain its current ASAT. How does your proposal differ with the Soviet proposal? Do you see the Soviet draft treaty as a realistic basis for negotiations?

Response: The Soviet Draft Treaty placed before the U.N. in 1981 suggests a serious interest in reaching an arms control agreement in space weaponry. The Soviet draft contains some elements that are worthy of serious consideration, even though the treaty draft is not acceptable as it stands. The degree to which it is unacceptable can be gauged from the remainder of this response.

The most important differences between the Soviet draft and the one put forward by us are that our draft forbids:

a) Tests against space objects in one's possession;

b) Tests from weapons on the ground;

c) Tests against objects on the ground or in the atmosphere from weapons in space.

Furthermore, our draft does not permit attacks against space objects that are in violation of the treaty's provisions; it addresses this problem in the traditional manner, by providing for withdrawal from the obligations of the treaty after due notice. Finally, our draft is bilateral.

QUESTION 5: Your proposal bans ASAT testing but not ground-based ASAT deployments. Given the fact that the Soviets have tested their ASAT, would your proposal be in effect a one-sided ban directed against the United States? If your proposal were in force, what incentives would the Soviet Union have for agreeing to dismantle their ASAT?

Response: Our discussion shows that our proposed treaty would not be to the "one-sided" disadvantage of the United States. If our treaty were to come into force, the USSR will have a tested ASAT, but one which has shown itself to be very unreliable, while the US would have under advanced development a more flexible and potent ASAT that had not yet been tested. Under the treaty regime we propose, the US would probably be closer to a prompt, flexible, all-altitude ASAT system than the USSR, while neither existing capability would pose much of a threat to those satellites on either side that are vital if nuclear war should break out.

In striking a balance of advantage versus disadvantage, one must consider factors other than the capabilities of the two ASAT systems. Since the United States is, on balance, more dependent on satellites for its security, anything that inhibits the evolution of the Soviet ASAT threat could be viewed as a "one-sided" advantage for the US.

The main incentive the Soviets would have for agreeing to dismantle their ASAT, would be their awareness that their current ASAT system would become progressively obsolete anyway. In the absence of space tests, the Soviets would

be left with an unreliable interceptor based upon 1960s technology, while the U.S. remained free to adopt sophisticated measures for protecting and diversifying its satellite functions.

QUESTION 6: Even if the Soviet ASAT capability is viewed as limited, does it not amount to a significant threat, given the high level of U.S. dependence upon a relatively small number of satellites?

Response: The Soviet ASAT, as presently constituted, could, over a period of several days, destroy a significant portion of our space-based capability for photo reconnaissance, which is of greatest importance in peacetime. It has quite limited capability against the remainder of our space-based command, control, communications, and intelligence systems; in particular, it has virtually no capability against that portion of the system that would be employed by the strategic forces in wartime. Nevertheless, the US should consider the desirability of various measures for protecting its satellites, or, for example, of providing ground-based back-up C systems for satellites important to theater conflicts.

QUESTION 7: We have previously used national technical means of verification to observe the dismantling of launchers.

a) Did you consider an ASAT ban involving the dismantling of Soviet ASAT launchers?

b) If yes, why did you not adopt this as your proposal?

Response: a) We have considered an ASAT ban involving the dismantling of Soviet ASAT launchers.

b) We did not adopt this as our proposal because we see no way in which the Soviets could verify that the United States had destroyed its F-15 ASAT system, and the difficulty of negotiating a non-symmetric treaty far exceeds the additional benefit we would obtain by destruction of the existing Soviet ASAT. Furthermore, dismantling of the known Soviet launch sites would not guarantee that the Soviet Union did not retain some ASAT capability.

Our draft treaty does include a provision (Article V) requiring the sides to begin negotiations on this issue immediately after a ban on space tests of ASATs is reached. However, we also recognized that provisions for dismantling ASAT systems could be quite complicated, and would, at best, require long negotiations. Hence, we view our proposed ban on further ASAT space tests as an urgent and indispensable first step toward any wider ASAT arms control measures. (For other closely related remarks, see our response to Question 12).

QUESTION 8: Senator Matsunaga and I [Senator Pell] are cosponsoring a concurrent resolution, S. Con. Res. 16, expressing the sense of the Congress that the President should initiate talks with the Soviet Union and other governments to explore opportunities for cooperative East-West ventures in space, as an alternative to an arms race. Do you support such a resolution?

Response: We support the Resolution sponsored by Senators Matsunaga and Pell. We agree that cooperation in space would be an important ingredient in creating an atmosphere that would inhibit confrontation. But we do not think that

such cooperation, by itself, would preclude an arms race in space. Cooperation should be viewed as one component in a diplomacy that seeks to avert such a race; the other, indispensable component, is a treaty that restricts the evolution of space-based weapons.

QUESTION 9: Do you believe that a space-based ABM system of even limited capacity could ever be built?

Response: A spaced-based ABM system of **very** limited capacity could be built **provided** the enemy abstained from taking rather simple and relatively cheap countermeasures.

QUESTION 10: Do you believe that such a system could ever effectively protect the United States from nuclear attacks?

Response: We are persuaded that such a system could never effectively protect the United States from an intentional large-scale missile attack from the Soviet Union, and even less could it protect against the systems the Soviets would develop in order to penetrate, circumvent, and destroy such a defensive system.

QUESTION 11: If we do not institute effective controls on weapons in space, what do you think will be the result?

Response: Without an effective ban on weapons in space, and a ban on antisatellite tests and activities, we are persuaded that the striving for ASAT and ABM capabilities could lead to war in space during what would otherwise have been peacetime, which would almost certainly lead to war on earth. This is so because it is very much simpler to achieve an ASAT capability than an ABM capability. Satellites are intrinsically more vulnerable than ballistic missiles; furthermore, the nature of the satellite's trajectory allows ample time for target acquisition, and for repeated attacks. Any space-based BMD capability, therefore, has an inherent ASAT capability, even if its potency against ICBMs is actually minimal. In particular, such a nascent ABM system can preemptively destroy an imagined ABM system belonging to the other side. Furthermore, either side can, at an early stage, station space mines that have the capacity for preemptive destruction of any satellites carrying ABM systems deployed by the other.

QUESTION 12: Why doesn't your draft treaty ban land-based ASATs? Would you favor such a ban if effective verification could be worked out?

Response: Our treaty bans all **tests** of land-based ASATs in space or against objects in space. Effective verification of a provision that also bans **possession** of land-based ASATs would require very intrusive verification measures, including extensive on-site inspection. For example, the U.S. ASAT interceptor and its launch booster are fairly small and could readily be hidden in many places at U.S. military facilities. Even the U.S. might find such intrusive on-site inspection at military bases unacceptable. As for the Soviet ASAT, even though it is large it could be launched some of the boosters used in the Soviet space program (see response to Question 3, however). Therefore dismantling of the launchers that have been used for Soviet ASAT test shots would not, by itself, guarantee that

there was no remnant Soviet ASAT capability.

One must bear in mind that the existing Soviet ASAT is intrinsically of rather limited capability. The prevention of any significant enhancement of that capability should therefore be the **primary** objective of U.S. policy, not the elimination of a relatively minor threat.

We recognize that a comprehensive ban on ASAT possession would be desirable, and for that reason our draft treaty, through Article V, obligates the parties to promptly begin negotiations towards that end as soon as the ASAT test ban is in place. If a treaty that would adequately verify lack of possession could be formulated, we certainly would support it. But given the limited political capital and human resources available for any negotiation, and the urgent need for a viable restriction on the growth of ASAT capabilities, we do not favor a negotiation position that may sacrifice the attainment of an ASAT test ban to the search for a ban on possession.

G = Geosynchronous orbit: Satellite moves with same period as the Earth at an altitude of approximately 35,600 km.
♦♦ = Statistic uncertain or unavailable using unclassified literature.
* = DSCS III is follow-on to DSCS II; same complement is planned.
** = NOVA satellites are being incorporated into the Transit network.
*** = AFSATCOM equipment is housed on "host" SDS, FLTSATCOM, LES, and DSCS III satellites.
@ = NAVSTAR plans call for a network of 18 operational satellites and three spares by 1988.
Apogee = Highest known point of orbit above the earth, given in km.
° = Other nuclear explosion detection sensors are aboard DSP and SDS satellites. The NAVSTAR system will house an advanced nuclear explosion detection system called IONDS beginning with NAVSTAR-8. Soviet nuclear detection sensors are most likely on their early warning and/or Molniya communication satellites.
Complement = Indicates the nominal number of satellites in a given network; + designates spares in orbit; ( ) = uncertain complement.
Inclination = Highest latitude reached N and S, given in degrees.
Period = Time it takes to complete one orbit, given in minutes.
Perigee = Lowest altitude of same orbit as apogee, also given in km.

SPACE WEAPONS, THE KEY TO ASSURED SURVIVAL

INTRODUCTION

As a result of congressional efforts to ban U.S. testing of weapons in space[1] and the recent testing of an anti-satellite (ASAT) weapon by the United States, increased attention is being directed to the question of whether the United States should have a space weapons[2] capability. Given the Soviet space weapons and treaty compliance record, along with the benefits to U.S. military security, the continued development of space weapons is in the U.S. national interest. Perhaps more important, a ban on space weapons would prevent the U.S. from deploying defensive space weapons as part of the strategic defense system envisioned by President Reagan. Such a strategic defense system would help protect the U.S. homeland from nuclear attack, reinforce deterrence, protect U.S. conventional forces and satellites from Soviet threats, and help stabilize crisis situations.

The control of space weapons through a negotiated agreement with the Soviets is a flawed idea. First and foremost, an ASAT ban would deny the U.S. the opportunity to develop and deploy the most essential feature of a strategic defense system--a ballistic missile defense (BMD) system. A BMD system would inevitably have ASAT capabilities and would be banned also. The U.S. thus would be locked into reliance on offensive nuclear forces to deter attack, and the threat of almost total societal destruction in a nuclear conflict would remain.

Second, an ASAT ban would not even accomplish what its proponents claim it would, that is, the protection of U.S. space assets. Such a ban would be virtually impossible to verify, and the Soviets' compliance with past arms control agreements is poor enough to suggest that, given the opportunity, they would find ways to circumvent an ASAT ban.

Note: Nothing written here is to be construed as necessarily reflecting the views of The Heritage Foundation or as an attempt to aid or hinder the passage of any bill before Congress.

There are, of course, many technological barriers left to cross before the U.S. achieves an effective strategic defense. But the potential benefits of space weapons are far too great--and the present dangers far too real--to bargain away a chance for real security.

BACKGROUND

Soviet long-range, nuclear-tipped ballistic missiles could destroy the U.S. as a viable society in hours, if not minutes. Early in the missile age U.S. scientists recognized the potential of space weapons to shoot down Soviet missiles as they travelled through space in high arcs to targets in the United States. The Eisenhower Administration in 1959 initiated a crash research and development effort, called Project Defender, to develop a multi-tiered ballistic missile defense force with space weapons in the first layer.[3] Although early studies were optimistic about technical feasibility, Project Defender was cancelled in part because the Soviet ICBM threat did not materialize as soon as expected and because the Kennedy Administration wanted to build up U.S. strategic offensive and conventional forces for deterrence.

Since the mid-1960s, the U.S. has based its security against nuclear attack solely on deterrence through retaliation. U.S. thinking about strategic nuclear affairs has been dominated by the view that defending populations against missile attack is not cost-effective. Many opponents of strategic defense also have subscribed to the doctrine of "mutual assured destruction" (MAD), which holds that to deter nuclear war the U.S. and the Soviet Union must have the capability to inflict "assured destruction" (massive civilian casualties and economic devastation) on each other. According to MAD, defending populations is bad, because it would upset the "balance of terror" and be perceived as a threatening bid for nuclear superiority by the other side. The result: a futile arms race and increased tensions between the superpowers. Under the sway of MAD, the U.S. government abandoned plans for a nationwide anti-ballistic missile (ABM) system in the mid-1960s, virtually dismantled U.S. civil and air defenses, and in 1972 signed a treaty with the Soviet Union limiting deployment of ABM systems to two sites (later reduced to one), thereby foreclosing the option of population defense.

Changes in the decade and a half since anti-missile defenses were rejected, however, are sufficient to warrant a reappraisal of strategic defense. Science has made tremendous breakthroughs on many fronts. A 1983 study by a group of top scientific experts (the Defense Technologies Study Team) concluded that technological advances of the last 25 years and those anticipated in the next 10 years make space-based ballistic missile defense feasible even against sophisticated Soviet countermeasures.[4] Advances in ground-based missile defense technology and anti-bomber/anti-cruise missile technology also have been considerable.

The strategic need for population defenses is far greater today than in the mid-1960s. The Soviet Union has never accepted U.S. views of deterrence, which stress the need for mutually secure second-strike forces. In accordance with its explicit nuclear war-winning strategic doctrine,[5] the Soviet Union has deployed a large force of very powerful land- and sea-based ballistic missiles. Using less than one-half of its total force, the USSR could destroy in a first strike up to 90 percent of America's silo-based ICBMs, 70 percent of the U.S. strategic bomber force, 40 percent of U.S. missile firing submarines, and key components of the U.S. command and control structure essential for effective retaliation.[6]

Soviet Strategic Defense

The Soviets also have invested heavily in strategic defenses to protect vital Soviet military, economic, and political assets from whatever retaliation the U.S. could muster after a Soviet first strike. Soviet air defenses, for example, comprise 2,500 interceptor aircraft, 10,000 surface-to-air missiles (SAMs), and 5,000 radars--which are being upgraded with new interceptors with look-down/shoot-down radars and missiles, new SAMs, and airborne warning and control aircraft (AWACs) to defend against low flying U.S. bombers and cruise missiles.[7] The Soviets spend about $3 billion a year on civil defense programs, which are capable of reducing Soviet civilian casualties to World War II levels under certain conditions.[8] (Congress appropriated $169 million for U.S. civil defense in FY 1984.)

The Soviet Union signed the 1972 ABM treaty not because Soviet leaders agreed that populations should remain defenseless but, more likely, because they wanted to prevent the U.S. from protecting its ICBMs and other strategic assets from a Soviet attack.[9] Since 1972, the Soviet Union has energetically pursued ABM research and development--the U.S. dismantled its one ABM site in 1976--and is currently upgrading its ABM system around Moscow with new radars and interceptors.[10] Some of the upgrades violate the 1972 ABM Treaty. Reportedly, the Soviet Union has built facilities for mass production of ABM system components that would give the USSR the capability for rapid deployment of a nationwide ABM system.[11]

The Soviet Union is also developing ground- and space-based directed energy weapons (lasers and particle beams)[12] for destroying U.S. ballistic missile warheads. According to the Defense Department, the USSR is spending three to five times more than the U.S. on research and development of laser weapons and could deploy the world's first orbiting laser weapon satellite in the next five years,[13] thus providing valuable operational experience for a multi-platform space missile defense system that could be deployed around the turn of the century.[14] The Soviets are already conducting tests of pointing and tracking mechanisms for laser weapons[15] (similar U.S. experiments are not scheduled until 1987) and apparently have test fired an experimental ground laser weapon located at Sary Shagan against Soviet reentry vehicles.[16]

Thus, it is clear that the unrelenting offensive buildup by the Soviets jeopardizes the survival of American nuclear deterrent forces. The Soviets' defensive measures have further degraded the effectiveness of the U.S. deterrent and their continued research, development, and production confront the U.S. with the disconcerting possibility of a rapid expansion of Soviet defensive capabilities and a potentially decisive Soviet strategic superiority.

BENEFITS OF U.S. SPACE WEAPONS

Why Strategic Defense?

To offset Soviet advantages in the strategic nuclear balance, the U.S. must enhance the survivability of its offensive nuclear forces and improve their capability to threaten important Soviet military targets. To maintain U.S. security in the long run, however, requires a fundamental change in the U.S. force posture: deployment of defense systems to protect the U.S. homeland from nuclear attack.

There are at least four strong arguments for the development of a strategic defense capability:[17]

1) Strategic defense would bolster deterrence by denying the Soviets the ability to destroy U.S. retaliatory nuclear forces and other U.S. economic and military assets. With less certainty of success, the Soviets would be less inclined to attack, even in crisis situations.

2) Strategic defense would more effectively deter the Soviets from limited nuclear aggression against U.S. allies. By defending the U.S., the credibility of an extended U.S. nuclear umbrella could be improved. The confidence of U.S. allies in U.S. ability and will to assist in their defense would also be restored.

3) Strategic defense would limit the danger of accidental nuclear war. Additional reaction time for leaders would be provided. Accidental launches, rather than detonating on U.S. soil, would be destroyed, thus lessening the chances of escalation.

4) Strategic defense is specifically intended to save lives and limit damage. Given the potentially catastrophic consequences should deterrence fail, such an approach is eminently practical and profoundly more moral than current strategic doctrine which relies heavily on mutual assured destruction.

Space weapons would play a critical role in a strategy of U.S. homeland defense, the key to which is to deploy multiple layers of defense. As Soviet missiles passed through each defense layer, fewer and fewer would survive, thus making the task of defense easier and more effective for each successive layer. It is important to attack Soviet missiles as soon as possible to allow

for multiple defense engagements and to destroy missiles before they disperse their multiple warheads. An effective strategic defense force posture, then, should include space-based anti-ballistic missile weapons capable of destroying Soviet missiles in their vulnerable boost phase (the first few minutes of flight) and space- or ground-based weapons capable of destroying missiles during their gliding stage in space.

The Soviet ASAT Threat

In addition to their contribution to strategic defense, space weapons could help protect U.S. satellites from a growing Soviet ASAT threat. The U.S. depends heavily on satellites for a number of military functions--communications (over 70 percent of U.S. overseas military communication travels by satellite), surveillance, reconnaissance, navigation, and meteorology. This dependency is increasing. Of particular importance to U.S. security are those satellites supporting the U.S. nuclear deterrent forces by providing command, control, and communications channels, early warning of Soviet missile launches, tracking of missile flight paths, damage assessment, and post-attack reconnaissance. These functions are critical for planning and executing controlled retaliatory nuclear strikes against strategically vital Soviet targets (such as nuclear missile silos, command bunkers, and centers of political control). As the Scowcroft Commission and nuclear strategists in both Democratic and Republican administrations have recognized, the capability to reply in kind in a controlled war to the full spectrum of possible Soviet nuclear attacks is essential for stable deterrence.[18]

Destruction of U.S. command, control, and intelligence satellites in a surprise first strike to paralyze U.S. strategic nuclear retaliatory forces seems to be a high priority in Soviet war plans.[19] A large-scale 1982 Soviet nuclear war exercise,[20] for example, commenced with a simulated attack on a U.S. strategic satellite by a Soviet ASAT system--the only ASAT system currently operational.[21] This system consists of a "killer satellite" launched from a variant of the SS-9 Scarp ICBM into a co-planar, intersecting or near orbit to the target.[22]

Two versions of the Soviet ASAT system have been tested: a radar guided satellite that explodes on command near the target; and an infrared guided system that fires pellets at the target. The capability of the Soviet orbiting ASAT system is limited but not insignificant. Although the infrared system has not yet been tested successfully, the success rate of the radar system is 70 percent. Only a few launch pads are dedicated to the ASAT mission, and the Soviet ASAT system is effective only against U.S. satellites orbiting below 900 miles, primarily reconnaissance satellites. On the other hand, the Soviets are modifying their huge SL-12 booster to launch "killer satellites" against U.S. early warning and communications satellites in high orbit,[23] and they may be able to modify their ASAT weapon to perform multiple kills and to function as a space mine.

The USSR is also developing and testing ground- and space-based directed energy and conventional weapons for attacking U.S. satellites in all orbits. Launch of a Soviet prototype orbiting laser ASAT weapon is expected within the next five years, with perhaps six orbiting laser ASAT platforms deployed by 1990.[24] In April 1981, the Soviets launched a large 15-ton maneuvering spacecraft, Cosmos 1267, which reportedly "carried ejection ports for small infrared homing torpedoes capable of destroying military satellites on impact."[25]

U.S. Space Weapons and the Defense of U.S. Satellites

Ensuring survivability of U.S. satellites against Soviet ASAT weapons poses a major challenge to U.S. defense planners. Four methods of enhancing the survivability of U.S. satellites have been discussed: (1) a treaty banning the testing and deployment of ASAT weapons; (2) use of passive survival aids; (3) deployment of U.S. ASAT weapons to deter Soviet ASAT attacks; and (4) deployment of a space defense system to defend U.S. satellites.

An ASAT weapons ban is not the solution to the problem. Because ASAT weapons tend to be small, easy to hide, and easy to disguise, verification of such a treaty would be most difficult.[26] And lack of Soviet compliance with existing arms control treaties raises serious doubts about their compliance with an ASAT treaty.

There are a number of "passive" measures by which the U.S. could enhance satellite survivability, some of which the U.S. government is already funding.[27] Using a wide variety of such measures, the U.S. could probably ensure a high degree of survivability for its satellites against current Soviet ASAT capabilities. The effectiveness of passive measures against later generation ASAT weapons, however, is uncertain.[28]

Trying to deter a Soviet attack on U.S. satellites by deploying a U.S. ASAT system to threaten Soviet satellites (survivability through deterrence) is probably not the solution to U.S. satellite vulnerability. The Soviets are less dependent on satellites for military operations than is the U.S. and, hence, might find it militarily worthwhile to sacrifice their satellites for those of the United States.[29]

In the absence of an ASAT ban, the U.S. could use space missile defense weapons to help protect U.S. satellites against Soviet ASAT attacks. U.S. laser missile defense weapons, for example, or even the new unsophisticated U.S. ASAT weapons just tested could be used to shoot down Soviet space mines. A ballistic missile defense would also improve the survivability of the vulnerable ground installations, which control many U.S. satellites.

In the final analysis, if the U.S. cannot ensure an adequate level of survivability for its satellites at an affordable cost, it may have to rely on more survivable atmospheric systems to perform those functions now performed by satellites. As John

Pike, space analyst for the Federation of American Scientists, has pointed out:

> Surrogate satellites offer a very attractive survivability option. Indeed, the most survivable "satellite" may be an airplane. High Altitude Remotely Piloted Vehicles can provide excellent in-theater weather and reconnaissance information, and a network of these drones could provide theater and transoceanic communications links.[30]

In short, even if U.S. satellites cannot be adequately protected by passive and active measures, there remain ways to ensure that U.S. armed forces can still successfully perform their military missions.

Space Weapons and U.S. Nuclear Force Survivability

Under current conditions, even more than satellites, many ground- and air-based elements of the U.S. strategic deterrent force--satellite tracking and control facilities, airborne and underground command posts, ground-based communications receivers and transmitters, radars, strategic bomber bases, and land-based ICBMs--would suffer extensive damage from a Soviet first strike. U.S. nuclear forces probably would be left blind, paralyzed, and seriously weakened, significantly impairing U.S. ability to implement its nuclear strategy of controlled limited nuclear counterstrikes against Soviet strategic forces. To some extent, passive measures could increase the survival chances of the U.S. nuclear force. Examples: ICBMs could be redeployed in a mobile or multiple protective shelter mode; communication systems could be hardened against nuclear effects, made mobile, or supported with redundant systems. Yet passive measures might not offer enough protection.[31] Active defenses, including weapons to intercept Soviet missiles in space, could substantially enhance strategic force survivability against present and future Soviet first-strike threats. At the minimum, space weapons would complicate Soviet planning for a first strike. The Soviets would not be able to foresee which of their missiles would be destroyed and which of their targets would consequently escape destruction. Adding to Soviet uncertainties clearly enhances deterrence.

Space Weapons and Conventional Force Survivability

The Soviets deploy spacecraft that pose serious threats to U.S. military forces. These include:

- radar and electronic ocean reconnaissance satellites (RORSATs and EORSATs), which track U.S. aircraft carrier battle groups and provide targeting data for Soviet air- and sea-launched cruise missiles and Soviet anti-carrier ballistic missiles;[32]

- manned orbiting space stations, which could provide extremely valuable reconnaissance information about U.S. force deployments;[33]

- navigation, communications, and reconnaissance satellites;
- unmanned "space plane" weapons now being developed, which could deliver nuclear weapons against U.S. carrier task forces.[34]

In some limited way, a U.S. ASAT capability might deter Soviet aggression. Despite the fact that the USSR is less dependent on satellites than the U.S. for important military functions, Soviet satellites contribute significantly to their military potential and that dependence is growing. Should conflict occur, there are passive measures, such as electronic jamming, that U.S. conventional forces could use to counter Soviet space systems. Their effectiveness is uncertain, if only because "counter-countermeasures" are closely guarded Soviet military secrets. Given the current asymmetry of this significance, for the U.S. to attack Soviet satellites first during a conflict makes little sense. If, however, the Soviets were to initiate a war in space by attacking U.S. satellites, a U.S. ASAT capability would be useful in defending U.S. forces. While ideally U.S. forces should be able to fulfill their missions facing threats enhanced by Soviet spacecraft, there can be no argument that reduction of the threat would be desirable.

As noted previously, if the Soviet ASAT threat grows, the utility of U.S. ASAT capability also will grow because of its ability to provide active defense for U.S. space assets. This will make U.S. ASAT capabilities even more essential in the future.

U.S. SPACE WEAPONS PROGRAMS

Technological Options

The U.S. at last is developing and testing a variety of space weapons. In response to the Soviet ASAT threat, the Carter Administration in 1977 approved development of a U.S. ASAT weapon and supported research and development of directed energy weapons (DEWs) for possible use in a variety of space missions, including defense of U.S. satellites (DSAT). In March 1983 President Reagan endorsed the development of space weapons for missile defense of the U.S. population.

The Air Force has just begun testing the booster stage of its ASAT weapon.[35] This system consists of an "impact kill" infrared guided miniature homing vehicle (MHV) launched from a two-stage rocket carried to high altitudes by an F-15 supersonic fighter. As currently configured, the MHV can destroy only Soviet satellites orbiting below 250 miles, but it could be effective against high altitude Soviet spacecraft and "killersats" if mounted on an earth launched booster.

Like the Soviet Union, the U.S. is developing directed energy weapons. The laser development effort, managed by the Pentagon's Defense Advanced Research Projects Agency (DARPA), has focused so

far on a 5-megawatt chemical laser suitable for limited ASAT missions. The Administration's Defense Technologies Study Team, however, has recommended parallel development of more powerful laser weapons, including ground-based "excimer" lasers and nuclear powered X-ray systems, for use against Soviet ballistic missiles.[36] A restructuring of the laser program is in progress to reflect the new mission of ballistic missile defense. Other laser technology programs include development of target acquisition, laser pointing, and tracking mechanisms (Project Talon Gold) and development of large mirrors for laser beam focusing and control. The development timetable of laser weapons is contingent on funding levels, but some experts believe that a U.S. prototype orbiting space defense laser weapon could be ready for operational testing in the early 1990s.

Because of their high energy density, neutral particle beam weapons would be more effective than lasers against Soviet ballistic missiles, but their development lags considerably behind that of lasers.[37] As an alternative to directed energy weapons, some scientists have urged the Defense Department to look at conventional off-the-shelf technology for a rapidly deployable space missile defense system. The "High Frontier" study, for example, recommends deployment of a multi-tiered BMD system with the first line of defense held by 432 orbiting platforms each armed with about 45 infrared rockets for intercept of Soviet missiles in their "hot" boost phase.[38] If effective, such a system could be cheaper and quicker to deploy than a laser system.

OTHER ISSUES

Military Effectiveness

Obviously, space weapons will not be cheap. There are no reliable cost estimates yet, but a baseline space defense missile force, capable of destroying a high number of Soviet missiles, could cost from $100-$200 billion. Even if space weapons could be overcome, deployment would still be desirable, if the cost to the Soviets of defeating them were roughly equivalent to, or greater than, the cost of deployment to the U.S. Such a system would presumably offer some benefit by retaining at least a degree of effectiveness and would, at the very least, divert Soviet military resources from more directly threatening programs.

Although space weapons present serious technological challenges, almost all scientists agree that they are technically feasible in the sense that the U.S. (and the Soviet Union) can build beam weapons powerful and accurate enough to destroy ballistic missiles. Critics claim, however, that space weapons have two fatal defects. First, the Soviets can cheaply counter U.S. space weapons by: using ablative coatings or fluids to shield Soviet missiles from lasers; spinning missiles to prevent laser heat buildup; polishing missile skins to reflect laser beams; jamming laser wavelengths; and shielding booster rocket plumes, deploying flares, or modifying boosters for shorter rocket burns to confuse infrared sensors. Second, they claim that U.S. space

weapons would be vulnerable to attack by Soviet space mines, nuclear weapons, amd laser weapons.[39]

These countermeasures pose significant challenges to U.S. space weapons. It is not clear, however, that Soviet countermeasures would be cheap or that the U.S. could not successfully deal with them at an affordable cost. For example, the Soviets spent massive sums of money to develop and procure their current force of multiple and single warhead ICBMs and submarine launched ballistic missiles. To ensure adequate penetration of a U.S. space missile defense force, the Soviets would have to rebuild missiles with hardened skins or deploy more missiles--at considerable cost.

There are also potential U.S. countermeasures to protect U.S. space weapons against Soviet attack. For example, U.S. space weapons could be hardened against nuclear effects, such as electromagnetic pulse. It is a long way from the "back of the envelope" design of countermeasures to deployment of a cheap effective capability. There are, for example, countermeasures to tanks such as anti-tank guns, missiles, mines, and other weapons (many much cheaper than tanks), yet tank forces still win battles. The Defense Technologies Study Team reviewed a wide range of possible Soviet counters to U.S. space defense weapons. It concluded that an effective space anti-missile defense is still achievable and affordable. While the DTST may be wrong, it is too early in the development of space weapons for confident assessments that space weapons are not cost-effective. The history of military technology is replete with false predictions about the lack of feasibility and ineffectiveness of various weapons systems. Certainly, the military potential of space weapons justifies a well-funded program of research, development, and testing.

Space Weapons and Stability

Many critics of space weapons worry that U.S. deployment of such systems would be "destabilizing," that is, it would make war more likely. More specifically, these critics argue that:

- U.S. deployment of space weapons would create a hair-trigger situation in which each side would be tempted to attack the other side's satellites and space weapons first in time of crisis to prevent the destruction its own valuable satellites and space weapons;[40]

- Soviet leaders are likely to see U.S. space missile defense weapons as giving the U.S. a war winning capability and decide to destroy U.S. space weapons before they become fully operational;

- U.S. deployment of space weapons would intensify the arms race, as each side deployed weapons to prevent the other side from achieving military superiority. The result is increased superpower tension

Stability is a proper concern of U.S. defense planners, but these arguments are based on some questionable assumptions.

It is, of course, quite possible that the U.S. can protect its satellites and space weapons from Soviet attack. As long as U.S. defensive systems were reasonably secure, the Soviets would be less certain of military success and thus less likely to strike in a crisis situation. However, even if the U.S. deployed space weapons with a reasonable degree of confidence in their effectiveness and survivability, there would be a possibility that the Soviets could develop unforeseen countermeasures that would place those space weapons in jeopardy. Even this development would not necessarily be destabilizing.

First, space defense weapons complement strategic nuclear offensive forces but do not replace them. The U.S. should maintain retaliatory forces that are survivable in their own right. Thus even if the Soviets could overcome U.S. defenses, they would still face a retaliation in kind to the full spectrum of attacks they might launch.

Second, given the direction of recent Soviet research and development and the significance of strategic defense in Soviet doctrine, it is likely that the Soviets will attempt to deploy a force of space-based missile defense weapons, particularly if the U.S. does so. If both sides' space weapons are vulnerable, the result is not destabilizing. Mutual vulnerability of offensive nuclear weapons is destabilizing. The existence of defensive systems (vulnerable or not) means that, if war should come, the first shots would inevitably be fired in space, thereby providing an additional threshold to be crossed prior to the use of nuclear weapons. This threshold would provide additional time to communicate with the Soviets to try to stabilize a crisis. Chances for successful U.S. retaliation would also increase by providing additional reaction time for time sensitive U.S. strategic offensive forces, such as bombers. Deterrence should thus be strengthened as well. Provided the U.S. maintains a sufficient offensive deterrent, the USSR should have no incentive to attack U.S. defense systems, even if they were vulnerable.

The argument has also been made that ASAT weapons would destabilize a crisis situation because the destruction of communications and intelligence satellites would diminish the intelligence, command, and communication capabilities necessary to control escalation. Even with the advent of more capable ASAT weapons, this argument is flawed. An attack on U.S. satellites would be an act of extreme provocation that would make sense only in the context of a larger conflict. In a lower level crisis there would be little or no incentive to attack satellites, thus leaving U.S. crisis control assets intact. Even if the Soviets should attack U.S. satellites in a lower level crisis, there would be little chance of unjustified U.S. nuclear escalation. Current U.S. policy is not to retaliate with strategic nuclear forces until there is absolute confirmation of nuclear attack, that is, nuclear

explosions in the U.S. The destruction of U.S. satellites, however provocative, should not trigger U.S. nuclear retaliation.

Futhermore, deployment of new ASAT weapons will not take place in a vacuum; U.S. countermeasures (such as passive survival aids, active defenses, and more reliance on high altitude remotely piloted vehicles) can help ensure an adequate flow of information. It also seems odd that those arguing against ASAT weapons on the grounds of their effect on crisis stability are often opposed to strategic defense (which is designed to control escalation and limit damage) and wedded to MAD, a strategy that, in the event of a deterrence failure, logically ends in the deliberate execution of millions of people--hardly a model of escalation control.

The truly extraordinary suggestion has been made that the mere prospect of deployment of ballistic missile defense systems might trigger World War III.[41] The odds that the Soviets would strike preemptively if faced with U.S. deployment of space defense weapons are, fortunately, extremely low. U.S. deployment of space weapons does not directly threaten the Soviet Union. It would tilt the strategic balance in favor of the U.S. only if the Soviets did nothing. A balance would be maintained, however, if the Soviets deployed a comparable defense capability. For any rational Soviet leaders, mutual survivability of the superpowers through space defense should be preferable to nuclear war.

The argument that U.S. deployment of space weapons would fuel the arms race assumes falsely that the current Soviet military activity buildup is in reaction to U.S. weapons programs. But as Jimmy Carter's Secretary of Defense Harold Brown has pointed out, "When we build, the Soviets build. When we don't build, the Soviets build."[42] Twenty years ago, the Soviet Union embarked on a defense buildup, evidently aimed at achieving overall military superiority. This has proceeded at a steady pace, undeterred by a decade of detente, SALT, and a voluntary near-freeze of its arsenal by the U.S.

What U.S. deployment of space weapons can do is redirect Soviet efforts into more stabilizing and less threatening defensive systems. Mutual deployment of strategic defenses would create a new stable order in which the Soviet Union would have no incentive to launch a nuclear attack against the U.S.

Space Weapons and Arms Control

Many critics of space weapons look to arms control as the primary means to deal with the Soviet military threat. Arms control, however, has failed to reduce that threat signficantly. Indeed, since the onset of strategic nuclear arms control negotiations in 1969, the balance has shifted dangerously in the direction of Soviet nuclear superiority. The U.S., therefore, must rely on its own defenses for its security. In particular, Washington should not sign an arms control agreement with the Soviet Union banning space weapons. Such an action would deprive the

U.S. of its most important means of defending the American people against Soviet missile attack.[43]

U.S. experience with the Soviets regarding earlier arms control efforts suggests that arms control would be inadequate to deal with the threat of Soviet space weapons. The Soviets consistently resist tightly worded treaty provisions. As with SALT I, the result invariably is that Moscow fully exploits treaty loopholes to continue developing weapons of strategic importance. Even within the distressingly loose constraints of flawed treaties, Soviet compliance has been poor. Specifically, the Soviets have tested SAMs in an ABM mode for upgrading air defenses for anti-ballistic missile missions, developed and tested mobile radars and missile launchers, deployed battle management radars for a nationwide ABM system, and tested rapid reload launchers--all in violation of the ABM Treaty. The Reagan Administration has just issued a report further detailing Soviet arms control violations.

Crucial to any arms treaty with the USSR is the U.S. ability to verify Soviet compliance. A U.S. State Department assessment,[44] however, finds that the arms control agreement banning the testing and deployment of space weapons recently proposed by the Soviet Union (and similar to that proposed by U.S. space arms control proponents) would not be verifiable by U.S. surveillance satellites or ground-, sea-, and air-based listening posts operating on the periphery of the USSR. These so-called national technical means of verification are the only verification instruments Moscow has approved.

Arms control advocates argue that passive measures could protect U.S. satellites against any ASAT capabilities the Soviets could develop and deploy covertly in violation of an ASAT ban. Because an ASAT ban is so difficult to verify, it would seem that the Soviets could covertly deploy space mines and ASAT missiles on manned and unmanned spacecraft, in addition to their current orbiting killer satellite. The Soviets might not be able to covertly test new generation weapons sufficiently to warrant high confidence in their capability, but such weapons might still be effective if war broke out. The effectiveness of passive measures against covert deployment of these more sophisticated ASAT weapons is very uncertain. The signing of an ASAT ban with the Soviet Union is thus very risky.

In any case, space arms control advocates overestimate the determination of the U.S. to react promptly and forcefully to Soviet treaty violations. Although the U.S. government has substantial evidence of Soviet violations of SALT agreements, Washington has failed to adjust its arms control policy and defense programs. Pressure by U.S. arms control enthusiasts, who seem intent on preserving the arms control process despite Soviet treaty violations, has made it extremely difficult for the Administration to gain congressional support for a strong U.S. response to these violations.[45]

Arms control is not an end in itself. Proposals for limiting weapons deployments must be evaluated in terms of their effect on U.S. national security and their contribution to preserving world peace. A ban on space weapons would deprive the U.S. of the means to defend itself against nuclear attack even as the Soviets continued to build up their nuclear warfighting offensive and defensive capabilities.

CONCLUSION

Security sometimes is enhanced by new kinds of weapons. Example: the U.S. deployment of missile firing submarines, which gives the U.S. a survivable force that could retaliate if the Soviets attacked U.S. cities. Likewise, space weapons would enhance U.S. security by helping protect the U.S. population and U.S. military forces from Soviet nuclear attack.

Critics of space weapons are rightly concerned about the implications of space weapons deployment for the security of U.S. satellites. Their solution--an ASAT weapons ban--however, would foreclose the option of effective strategic defense. The U.S. must do much more to protect its satellites from new Soviet ASAT weapons. A full program of passive survival aids is needed, including deployment of spare satellites in space, design of satellites with a maneuvering capability, and hardening of satellites against nuclear effects. Deployment of space laser weapons in the 1990s would provide substantial additional protection. Ultimately, in wartime, the U.S. might have to reduce reliance on satellites for military support functions.

The Defense Department currently is constructing a detailed "road map" for the development of advanced space weapons. Congress should adequately fund a research and development effort leading to testing a prototype orbiting space laser weapon by 1990 and rigorous operational testing of a space missile defense system in the 1990s. At the same time, the U.S. should proceed with the testing and deployment of the miniature homing vehicle (MHV) anti-satellite weapon. It probably has some limited value in deterring Soviet attacks on U.S. satellites, and it could be used to defend U.S. satellites against Soviet killer satellites and to deny the Soviets use of valuable space systems in a conflict. It is essential, however, that the U.S. proceed immediately to reduce the vulnerability of its strategic nuclear forces to a Soviet first strike, for nuclear weapons will remain the bedrock of deterrence for the next twenty years at least.

Space weapons are not wonder weapons capable of giving the U.S. decisive military superiority. Nor are they cheap. But their potential contribution is a new kind of security--based on protecting U.S. lives rather than leaving them hostage in a dangerous "balance of terror."

If space defense could be achieved, it would be strategically imprudent and morally irresponsible not to deploy space weapons to defend the U.S. homeland against nuclear attack.

NOTES

1 Resolutions to de-weaponize space have been introduced in both Houses of the 98th Congress. These include: H.J. Res. 87, introduced by Representative Robert W. Kastenmeier (D.-Wis.), and H.J. Res. 120, introduced by Joe Moakley (D.-Mass.) with 76 co-sponsors, which call on the President to resume talks with the Soviet Union aimed at banning all weapons from space. (From 1977 to 1979 the U.S. and USSR met in three rounds of negotiations to discuss a ban on ASAT weapons. The talks have been suspended since the Soviet invasion of Afghanistan.) S.J. Res. 28, introduced by Sen. Paul Tsongas (D.-Mass.) is identical to the Moakley resolution. Senator Larry Pressler (R.-S.D.) has introduced S. Res. 43 calling for negotiations to ban ASAT weapons as a first step toward a comprehensive ban on all space weapons. Attempts to delete funding for testing and advanced procurement of the ASAT system from the FY 1984 defense budget were defeated by Congress, although funding for testing is contingent on a presidential certification that the U.S. is proceeding in good faith to negotiate a treaty with the Soviet Union banning ASATs or that such tests are necessary for national security.

2 In this paper, "space weapon" refers to any ground-, air-, or space-based weapon which is capable of destroying or otherwise rendering inoperable objects orbiting in or transiting space, including satellites and ballistic missiles and their warheads.

3 John Bosma, "Space and Strategic-Defensive Reorientation: Project Defender," Defense Science and Electronics, September 1983, pp. 58-65.

4 The Defense Technologies Study Team, directed by former NASA head, James C. Fletcher, was formed by the Administration to study the feasibility of space-based ballistic missile defense. The DTST's report, delivered to the White House in October, has not been made public, but for a discussion of its major findings, see Clarence A. Robinson, Jr., "Panel Urges Defense Technology Advances," Aviation Week and Space Technology, October 17, 1983, pp. 16-18; "Study Urges Exploiting of Technologies," ibid., October 24, 1983, pp. 50-57; and "Shuttle May Aid in Space Weapons Test," ibid., October 31, 1983, pp. 74-78.

5 For an analysis of Soviet nuclear doctrine, backed with copious citations from Soviet military writings, see Mark E. Miller, Soviet Strategic Power and Doctrine (Washington, D.C.: Advanced International Studies Institute, 1982) and Joseph D. Douglass, Jr. and Amoretta Hoeber, Soviet Strategy for Nuclear War (Stanford, California: Hoover Institution Press, 1979). Soviet nuclear doctrine stresses that the Soviet Union must have the capability to deliver a crushing blow to U.S. offensive nuclear forces and to defend the USSR against retaliation from surviving U.S. nuclear weapons.

6 George Wilson and Walter Pinkus "Missile Survival Questioned," Washington Post, May 9, 1983, p. 1; Harold Brown, Department of Defense Annual Report to Congress, Fiscal Year 1982, p. 111. Roughly 30 percent of the U.S. bomber force is on alert and about half of U.S. submarines are at sea at any given time; those forces would have a good chance of escaping a Soviet first strike.

10 Soviet ABM upgrades are discussed in "Soviets Test Defense Missile Reload," Aviation Week and Space Technology, March 8, 1983, p. 27, and Berman and Baker, op. cit., p. 149.

11 Clarence A. Robinson, Jr., "Soviets Accelerate Missile Defense Efforts," Aviation Week and Space Technology, January 16, 1984, pp. 14-16; Michael Getler, "Soviets Seen Progressing Toward a Missile Defense System," Washington Post, January 20, 1984, p. A25.

12 Laser weapons involve highly concentrated beams of light (photons) generated by a number of means including chemical reactions between hydrogen and fluoride gases (chemical lasers), exciting molecules of inert gases with electricity ("excimer" lasers), amplifying a laser beam with an electron beam (free electron lasers), or pumping a solid material with X-rays or gamma rays generated from a nuclear explosion. The different lasers produce different beams of different wavelength and strength. Laser weapons kill their targets by heating them, shock wave propagation, radiation, or a combination of these processes.

Particle beam weapons "work by accelerating subatomic particles--neutrons, electrons, or protons (a charged particle beam) or ionized hydrogen atoms (a neutral particle beam) at speeds approaching that of light, in very large quantities, creating an energy beam with a very high-energy density. Such a beam can best be described as a manmade lighting bolt which, upon reaching its target, shatters the surface and then penetrates deeply, thereby depositing its energy in a long narrow cone throughout the target." Kenneth Harmon, "Directed Energy Weapons," Grand Strategy: Countercurrents, August 15, 1982, pp. 2-8.

17 For a more detailed statement of these arguments, see Robert Foelber, "Strategic Defense: Avoiding Annihilation," Heritage Foundation Backgrounder No. 304, November 9, 1983.

18 For a classic statement of U.S. nuclear doctrine, formulated during the Carter Administration in Presidential Directive-59 and reaffirmed by the Reagan Administration, see Harold Brown, Department of Defense, Annual Report Fiscal Year 1981, p. 66.

19 For a discussion of Soviet ASAT doctrine, see Lawrence Freedman, "The Soviet Union and 'Anti-Space Defence,'" Survival, July-August 1977, pp. 16-23. In 1964, the USSR established a special anti-space branch of its air defense force "to destroy space systems used by the enemy for military purposes, in their orbits" using "special spacecraft and vehicles (e.g.,

satellite-interceptors), which may be controlled either from the ground or by special crews." Quoted in Freedman, p. 18.

20 The June 1982 test involved an anti-satellite test, two ICBM launches, an SS-20 launch, an SLBM launch, and two ABM firings simulating, according to some U.S. analysts, in logical sequence a first-strike against U.S. ICBMs coupled with an attacked against U.S. satellites, followed by defense against U.S. retaliatory strikes and a follow-up second strike against the U.S. using SLBMs. "Soviet Stage Integrated Test of Weapons, Aviation Week and Space Technology, June 28, 1982, pp. 20-21.

21 From 1963 to 1970, the U.S. experimented with two crude ASAT weapons--Thor and Nike-Zeus missiles armed with nuclear warheads. The Thor system was decommissioned in 1975, the Nike-Zeus in 1967. Presumably, the Soviet Union also has the capability to launch nuclear missiles at satellites. The Soviets claim that they have never tested ASAT weapons and that U.S. claims that the USSR has an operational ASAT system are "mythical." For a brief discussion of Soviet efforts to "disinform" the West about Soviet space weapons programs, see James E. Oberg, "Andropov's Orbiting Bombs: The Soviets' Outer-Space 'Peace' Strategy," Reason, December 1983, pp. 25-30.

22 The "near orbit" approach, whereby the killersat performs a "pop up" maneuver to bring it into close proximity to the target, is militarily the most effective approach, since attacks can be more easily disguised.

23 "Soviets Outspending U.S. On Space by $3-4 Billion," Aviation Week and Space Technology, July 19, 1982, pp. 28-29.

24 Covault, op. cit., p. 20.

25 David Baker, The Shape of Wars to Come (New York: Stein and Day, 1982), p. 167.

26 The difficulties of arms control as a method of securing U.S. space assets are discussed in greater length later in this paper; see also Colin Gray, op. cit., pp. 49-55.

27 Passive survival aids for satellites include: harden systems against nuclear effects, especially the electromagnetic pulse (EMP) phenomenon which can render electronic circuits inoperable, build maneuvering satellites that can evade Soviet ASAT weapons, stockpile spare satellites on the ground in high orbits in an inert state to be called down and activated in time of war, equip satellites with radar and infrared spoofing devices to provide false signatures to Soviet sensors, deploy decoy satellites, and equip satellites with umbrellas to deflect laser beams. For a discussion of threats and survival aids for U.S. satellites, see Robert B. Giffen, U.S. Space System Survivability: Strategic Alternatives for the 1990s (Washington, D.C.: National Defense University Press, 1982). Presidential Directive-37, signed in 1978, called for greater survivability of U.S. satellites.

28 This has led some space analysts, including military officers responsible for U.S. satellites, to favor an arms control agreement with the Soviet Union banning the testing and deployment of ASAT weapons. Civilian space arms control advocates tend to favor a treaty that would prevent the U.S. from testing and deploying its new ASAT weapon. Some military arms control advocates want to restrict only the testing and deployment of more advanced ASAT weapons.

29 For a description of Soviet satellites and the argument that loss of Soviet satellites would not constitute a major reduction in Soviet war-fighting capability, see Stephen M. Meyer, "Soviet Military Programmes and the 'New High Ground,'" Survival, September-October 1983, pp. 204-215. Colin S. Gray argues that Soviet dependence on satellites for successful nuclear operations is still considerable. American Military Space Policy: Information Systems, Weapons Systems, and Arms Control (Cambridge, Mass.: Abt Books, 1983).

30 "Anti-Satellite Weapons and Arms Control," Arms Control Today, December 1983, p. 1.

31 For example, U.S. airborne command posts can only stay aloft for 72 hours, even with air-to-air refueling, before they must land for brief maintenance. With defenses against Soviet missiles, the U.S. could selectively defend a certain number of airstrips to keep airborne command posts operating.

32 Soviet RORSATs use active radars powered by nuclear generators to detect U.S. surface naval vessels. EORSATs passively listen in on electronic emissions (radars, communications) to detect the location of surface vessels and possible submarines as well. Berman and Baker, op. cit., pp. 162-164. Robert Cooper, DARPA Director, has called Soviet ocean satellites "a major new threat" to U.S. naval forces. "Navy Warned of New Soviet Threat," Chicago Tribune, March 18, 1982, p. 5.

33 "Major aspects of the Soviet manned space programme are exclusively military. For example, it is well known that the Salyut space station has been outfitted in and tasked in two distinct versions: one for military missions and one for civilian missions. A wide range of reconnaissance, ELINT (electronic intelligence), and C3 (command-control-communications) tasks and experiments have been performed by Soviet cosmonauts during extended says in space....In 1981-2 cosmonauts were in orbit 286 days..." Meyer, op. cit., pp. 204-205. By contrast, the U.S. did not have a man in space from 1975-1981 and the U.S. record for space endurance is only 84 days vs. 211 for the Soviets. The Soviet Union is now developing a huge space station to be manned by 12-20 cosmonauts who could assist in constructing space weapons. "Soviets Outspend U.S. On Space by $3-4 Billion," Aviation Week and Space Technology, July 19, 1982, pp. 28-29.

34 The Soviets appear to be developing two versions of a space plane. The first is a small 2,000 pound unmanned orbiter which could be a more flexible weapon system than the Orbital and Fractional Orbital Bombardment Systems tested by the Soviets in the 1960s. The second Soviet space plane resembles the U.S. shuttle and could be ready for regular use within ten years. See Thomas O'Toole, "Soviet Test in Space May Be A-Weapons," Washington Post, March 17, 1983, p. A13; and James E. Oberg, "The Elusive Soviet Space Plane," Omni, September 1983.

35 For a brief account of the beginnings of the U.S. ASAT program, see U.S. Senate, Committee on Commerce, Science, and Transportation, Soviet Space Programs: 1976-1980 (Washington, D.C.: Government Printing Office, 1982), pp. 184-186.

36 Clarence A. Robinson, Jr., "Panel Urges Defense Technology Advances," Aviation Week and Space Technology, October 17, 1983, pp. 16-18.

37 Charged particle beam weapons would not work in space because the beams would be bent by the earth's magnetic field.

38 General Daniel O. Graham, High Frontier: A New National Strategy (Washington, D.C.: High Frontier Inc., 1982).

39 Daniel Kaplan, "Lasers for Missile Defense," The Bulletin of Atomic Scientists, May 1983, pp. 5-8.

40 A recent publication of the Center for Defense Information, for example, states: "Space weapons which threaten satellites increase incentives for a first strike. If both sides could suddenly lose their vital military satellites--and therefore much of their military capability--there is great pressure, especially in a crisis situation to launch nuclear weapons before the opportunity to do so is lost." "Militarizing the Last Frontier: The Space Weapons Race," The Defense Monitor, Vol. XII, Number 5, p. 7.

41 According to a publication of the Union of Concerned Scientists, "even the mere prospect of ABM deployment could spark hostilities. The imminent deployment of ABMs could temp an enemy to attack suddenly and decisively to disarm its opponent." The New Arms Race: Star Wars Weapons (Briefing Paper No. 5), p. 5.

42 Joyce Larson and William Bodie, eds., The Intelligent Layperson's Guide to the Nuclear Freeze and Peace Debate (New York: National Strategy Information Center, 1981), p. 19.

43 Space basing is required for a BMD system designed to intercept ballistic missiles in their flight. The most recent draft treaty proposed by the Soviet Union seeks to prohibit deployment and/or testing of space-based weapons "designed to hit targets on the Earth, in the air and in outer space." This presumably would exclude the Soviet ground-based ASAT weapons, but surely would include any space basing of U.S. ballistic missile defenses. A draft treaty by the Union of Concerned Scientists bans the deployment and testing of any ASAT weapons anywhere. It is difficult to conceive of a BMD system that would not have some ASAT capability also; to argue that the purpose of ASAT and BMD weapons is different does not change the inherent technological overlap. A copy of UCS treaty may be found in the Congressional Record, May 18, 1983, pp. S6991-6993.

44 Covalt, op. cit., pp. 20-22.

45 The deleterious effect on U.S. security of the lack of a coherent and determined compliance policy is discussed in "Soviet Treaty Violations and U.S. Compliance Policy," National Security Record, a monthly publication of The Heritage Foundation, December 1983.

MARCIA S. SMITH

The Militarization of Space and Other International Space Issues

From August 9-21, 1982, the United States and 93 other countries participated in the Second United Nations Conference on the Exploration and Peaceful Uses of Outer Space in Vienna, Austria. The conference was held under the auspices of the U.N. Committee on the Peaceful Uses of Outer Space (COPUOS) with the goal of assessing methods for assisting developing countries to benefit from space activities to the maximum extent possible. The conference turned out to be primarily a drafting committee for developing a final report for transmittal to the U.N. General Assembly, rather than a demonstration of the potential benefits of space activities. Among the most controversial issues discussed were: military uses of space; access to geostationary orbit; principles for remote sensing and direct broadcast satellites (DBS); technology transfer; and creation of a U.N. Centre for Outer Space.

PREPARATORY ACTIVITIES

The United Nations General Assembly scheduled UNISPACE'82 in 1980, thus giving all nations approximately two years to prepare for the conference. The conference secretariat, headed by Yash Pal of India, was charged with developing a draft conference report, for initial consideration by COPUOS and final approval at the conference. The 53 members of COPUOS were invited to submit national papers to provide input to the draft report. Once approved by the conference, the report would be transmitted to the General Assembly for action.

COPUOS is serviced within the U.N. organization by the Outer Space Affairs Division (OSAD). In 1980, the director of OSAD, a Czechoslovakian, retired and the United States expected that his deputy, an American, would assume that position. Early in 1981, however, it became apparent that the Soviet Union would insist that another Czechoslovakian be installed as OSAD Director. The United States objected to this, and to emphasize its position, anncunced that it would not participate in some of the preparatory activities for UNISPACE until the American was named Director. This dispute was not resolved until December 28, 1981, so for the entire year, the United States did not formally participate in UNISPACE preparations (for example, it did not submit a national paper or name a deputy-secretary general, and for several months, blocked publicity efforts for the conference).

The issue was finally resolved when outgoing U.N. Secretary General Kurt Waldheim decided that the American would serve as Acting Director until UNISPACE commenced, and then officially would become Director. The Czech would be his deputy and become Director once the American retires (in the spring of 1983).

As a result of this personnel dispute, the United States did not begin its preparatory activities until early 1982, only seven months before the conference. A State Department coordinator was named in March (Ambassador Gerald Helman) and soon thereafter James Beggs, Administrator of NASA, was named chairman of the delegation. The other members were not named until the end of July, however, two weeks before the conference. This precipitated concern in Congress that the delegation would not be prepared to deal with the issues which were likely to arise at UNISPACE.

One problem in this regard was that the United States insisted that UNISPACE was a technical conference, charged with dealing with technical issues such as remote sensing technology, and not with political issues such as the desire by many countries to have the right of "prior consent" over who has access to data obtained with remote sensing satellites and over what programming is beamed into their territory by direct broadcast satellites.

THE ISSUE OF "MILITARIZATION" OF SPACE

It also became apparent prior to the conference that a major topic of discussion would be the political issue of the increased military uses of space. This topic has been assigned to the U.N. Committee on Disarmament rather than COPUOS, so was not on the formal agenda of UNISPACE, but the 430 paragraph draft conference report which had been prepared by the UNISPACE'82 secretariat contained four paragraphs concerning the "militarization" of space.

During meetings in early 1982, COPUOS members reached agreement on all but 15 of the paragraphs in the draft report. The four on militarization were among the 15

THE RESULTS OF THE UNISPACE'82 CONFERENCE

that were bracketed to indicate they remained in disagreement. Since UNISPACE'82 had to reach final agreement on the entire report, it was clear that militarization would have to be discussed. Nevertheless, U.S. delegation leaders insisted that this would not be a major topic of discussion.

Opening Session of the Conference

Anyone who still believed that militarization of space would not be a focus at UNISPACE'82 would have been rudely surprised at the opening session. The first three speakers—U.N. Secretary General Javier Perez de Cueller, Austrian President Rudolph Kirchshlaeger, and Austrian Foreign Minister Willibald Pahr (who also served as President of the conference)—all mentioned the topic prominently in their initial remarks. For the remainder of the first week, 67 countries presented opening statements in the plenary sessions, and all but 4 (including the United States) mentioned militarization.

Proposed Working Group

At the beginning of the conference, Pahr suggested that a working group be established to deal with the four bracketed paragraphs on militarization so as not to hold up the work of the three committees which had been established to develop final wording in the draft report. The United States and the Soviet Union objected to this proposal, so no working group was created and the task of resolving this issue fell to the three committees. In order to expedite their work, the committees decided in turn to defer the militarization issue (together with other very controversial topics).

Committee 1 Debate

The first debate on militarization therefore did not occur until the second Monday at a special evening session of Committee 1. After an hour's debate on this topic, it appeared that agreement had been reached on the first sentence, but just as the committee chairman banged the gavel to indicate that the sentence had been adopted, the chief U.S. spokesman at that meeting informed the chairman that he could not accept any of wording that had been proposed.

Later he added that it was actually the "concept" to which he objected, not just the wording, so no language would be acceptable. Since it was apparent that consensus would not be reached that evening, the committee session was adjourned.

Final Resolution

Now that it was clear that the committees would not be able to deal with the issue, Pahr once again proposed creation of a working group; this time it was accepted. The group, called "Friends of the President," was established on Wednesday morning, and by Friday morning consensus had been reached on three paragraphs discussing the international concern over the potential arms race in space. This phrasing was a partial victory for the United States, which objected to the word "militarization" because it includes all military space activities (such as reconnaissance and communications) and not just the use of weapons in space. Why the United States did not suggest this wording at the Monday meeting, rather than standing alone in its opposition to all wording on military uses of space, is unclear. The three paragraphs were subsequently adopted by the conference as a whole.

OTHER CONTROVERSIAL ISSUES

In addition to militarization, there were several other very controversial topics discussed at UNISPACE, both those in bracketed paragraphs and those on which agreement had been reached within COPUOS. The major issues were: geostationary orbit, prior consent for remote sensing and direct broadcast satellites, technology transfer, and creation of a U.N. Centre for Outer Space.

Geostationary Orbit

Geostationary orbit (GEO) exists 35,800 kilometers above the equator, and an object placed there will retain a fixed position relative to a point on Earth. It is therefore extremely useful for space applications such as communications satellites.

Developing countries want special "*a priori*" planning schemes to be instituted which will reserve places in GEO for all countries, because they are concerned that the "good" slots and frequencies will be assigned to developed countries under the existing "first-come, first-served" scheme. The United States and other developed countries object to *a priori* planning because it could prevent use of various parts of the orbit and certain frequencies, even though there are no guarantees that a particular developing country would ever use them. They also point out that assignments are given only for the lifetime of a particular satellite, not in perpetuity, and that technological advances may render the problem moot by the time developing countries want to use the slots.

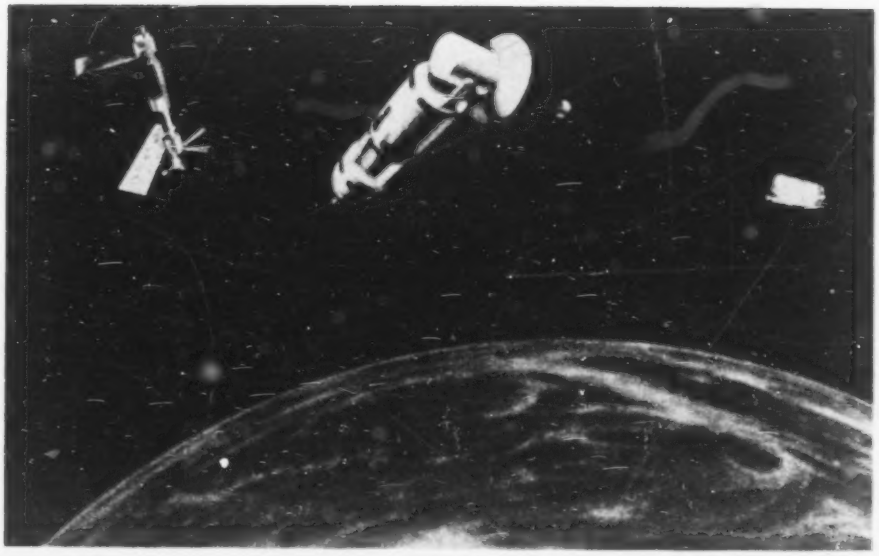
Another aspect of the GEO debate is that many of the equatorial countries want to be given special consideration in use of GEO because of their geographical position vis-a-vis that orbit. At UNISPACE, efforts by these countries to add language giving them special consideration were partially rebuffed by other countries, such as those at far northern latitudes where receiving signals from GEO satellites is difficult, who also feel they deserve special consideration.

The conference adopted wording stating that future planning schemes for GEO will take into account the needs of developing countries and the needs of countries "in special geographical positions."

Prior Consent

COPUOS has been debating proposed principles to govern international remote sensing and direct broadcast satellite (DBS) activities for more than a decade without resolution. Attempts were made by several countries at UNISPACE'82 to add language stating that a country

Marcia S. Smith is a specialist in aerospace and energy systems, Science Policy Research Division.



Artists concept of spaceborne laser weapon.

DOD

should have the right of prior consent over the distribution of data about itself from remote sensing satellites, and over the transmission of programming into its borders by DBS. These attempts were rebuffed, although language was added about the possible impact of these activities on national sovereignty, and stating that "it is now time" for agreement to be reached on principles governing these activities.

A new facet of the remote sensing issue arose at UNISPACE'82. Many developing countries wanted language stating that a sensed country should have priority access at a nominal cost to all data and information obtained about itself from remote sensing satellites. Compromise language was developed which states that sensed countries shall have "timely" access to all primary data (not data and information) under "reasonable conditions."

Technology Transfer

Developing countries wanted the UNISPACE conference report to call on developed countries to provide increased assistance to them and for greater international cooperation in space. The United States and other developed countries wanted language stating that developing countries have to take more responsibility for themselves. The final conference report reflects both points of view.

Centre for Outer Space

The original draft of the UNISPACE conference report had contained a recommendation that a new U.N. Centre for Outer Space be created to take over and expand the activities of OSAD. During preparatory actions on the draft report, this was toned down in response to concerns of the United States and other countries that such a move would require an increase in contributions to the U.N. assessed budget. Wording was added to the draft report that if such a Centre were to be created, most of the funding would come from voluntary contributions.

At the conference, this was further diluted, such that the final report simply states that either a new Centre could be created or the activities of OSAD could be expanded, and refers the matter to the General Assembly for consideration.

AFTERMATH OF THE CONFERENCE

UNISPACE'82 was supposed to be a conference concerned with helping the developing countries benefit from space activities. Whether or not this was accomplished is difficult to ascertain. Because the conference turned out to be primarily a drafting committee for developing final language for the report, delegates had little time to visit the exhibits or attend special demonstration sessions sponsored by the United States on programs such as Landsat, Space Telescope, and communications satellites.

On the positive side, however, 94 countries attended the conference, many of which were developing countries that are not members of COPUOS and therefore probably were not highly aware of activities in the space field. Their exposure to the issues, technical and political, will probably prove to be advantageous to them in the future.

The conference report, which contains the observations and recommendations of the countries attending the conference, will be considered by the General Assembly in

38-036 O - 84 - 79

its 1982 session. Since the report was arrived at by consensus, however, the recommendations are not strongly worded and probably will have little impact on space policies and programs.

Perhaps of more potential significance are two statements issued by the Group of 77 (a group of developing nations which is now composed of 120 countries) at the conference. Although they are not part of the official report, these strong views cannot be ignored since they represent so many nations. On militarization, the Group of 77 called on the two space powers to begin negotiations immediately on a ban on the testing, development, and use of all weapons in space.

As noted earlier, this issue has been referred to the U.N. Committee on Disarmament (CD). The U.S. position—that militarization should not be discussed at UNISPACE'82 because it has been assigned to the CD—was weakened by the fact that the United States opposes creation of a working group in the CD to deal with this issue (all other nations in the CD want such a group established). Whether UNISPACE will change the U.S. position is unclear, although the CD was meeting at the same time as UNISPACE'82, and there was no noticable shift.

Another aspect of this is whether militarization should be referred to COPUOS as well as to the CD, a matter which may be considered by the General Assembly this year.

Regarding remote sensing and DBS, the Group of 77 called on the United Nations to seek final approval of principles governing these space activities, and recommended that prior consent be one of those principles. The United States opposes prior consent because of its belief in free flow of information and freedom of speech. Draft principles on DBS may come up for a vote in the U.N. General Assembly this fall.

CONGRESSIONAL INTEREST

Prior to UNISPACE, the House Science and Technology Committee and the House Foreign Affairs Committee held hearings on U.S. preparations for the conference. Concern was focussed on whether the U.S. was adequately prepared for both the technical and political issues likely to arise.

Five members of Congress attended portions of the conference: Rep. Ronnie Flippo, chairman of the Subcommittee on Space Science and Applications of the House Science and Technology Committee; Rep. Daniel Akaka, Co-Chairman of the Congressional Space Caucus; Reps. George Brown and William Carney, members of the House Science and Technology Committee; and Rep. Wayne Grisham. In addition, staff members from the House Science and Technology and House Foreign Affairs Committees, the Congressional Research Service, and the Office of Technology Assessment, attended all or part of the conference.

Some of the issues of continuing congressional concern now that the conference is over include: an assessment of U.S. performance at the conference, particularly in terms of how well the major issues were anticipated; composition of the U.S. delegation to the conference and why the members were named only two weeks before the meeting convened; and what the U.S. position should be at the United Nations concerning the issue of military uses of space.

Hearings may be held this late fall either on UNISPACE specifically or on the general topic of U.S. space policy, at which UNISPACE is likely to be discussed.

OTA Background Papers are documents containing information that supplements formal OTA assessments or are outcomes of internal exploratory planning and evaluation. The material is usually not of immediate policy interest such as is contained in an OTA Report or Technical Memorandum, nor does it present options for Congress to consider.

CONGRESS OF THE UNITED STATES
Office of Technology Assessment
Washington, D.C. 20510

Preface

This background paper was prepared by Dr. Ashton B. Carter under a contract with the Office of Technology Assessment. OTA commissions and publishes such background papers from time to time in order to bring OTA up to date on technologies that are the subject of frequent congressional inquiry. After Dr. Carter's work was under way, Senators Larry Pressler and Paul Tsongas of the Senate Foreign Relations Committee requested that the resulting paper be made available to that Committee as soon as possible. OTA is issuing the paper in the belief that others in Congress and members of the public will find it of interest and importance.

An OTA background paper differs from a full-fledged technology assessment. Background papers generally support an ongoing assessment of broader scope or explore emerging technological issues to determine if they merit a fuller, more detailed assessment. On March 22, 1984, the Technology Assessment Board directed OTA to carry out a full-fledged assessment of "New Ballistic Missile Defense Technologies," for which this background paper will serve as one point of departure.

This paper was prepared for OTA's International Security and Commerce Program, under the direction of Lionel S. Johns (Assistant Director, Energy, Materials, and International Security Division) and Peter Sharfman (Program Manager).

Section 1
INTRODUCTION

This Background Paper describes and assesses current concepts for directed-energy ballistic missile defense in space. Its purpose is to provide Members of Congress, their staffs, and the public with a readable introduction to the so-called "Star Wars" technologies that some suggest might form the basis of a future nationwide defense against Soviet nuclear ballistic missiles. Since these technologies are a relatively new focus for U.S. missile defense efforts, little information about them has been readily available outside the expert community.

Directed-energy or "beam" weapons comprise chemical lasers, excimer and free electron lasers, nuclear bomb-powered x-ray lasers, neutral and charged particle beams, kinetic energy weapons, and microwave weapons. In addition to describing these devices, this Background Paper assesses the prospects for fashioning from such weapons a robust and reliable wartime defense system resistant to Soviet countermeasures. The assessment distinguishes the prospects for perfect or near-perfect protection of U.S. cities and population from the prospects that technology will achieve a modest, less-than-perfect level of performance that will nonetheless be seen by some experts as having strategic value. Though the focus is technical, the Paper also discusses, but does not assess in detail, the strategic and arms control implications of a major U.S. move to develop and deploy ballistic missile defense (BMD).[1]

This Background Paper grows indirectly out of President Reagan's celebrated television speech of March 23, 1983, in which he called for a "long-term research and development program to begin to achieve our ultimate goal of eliminating the threat posed by strategic nuclear missiles."[2] Pursuant to the President's speech, the Department of Defense established a Defensive Technologies Study Team under James C. Fletcher (of the University of Pittsburgh) to prescribe a plan for the R&D program. A parallel effort, called the Future Security Strategy Study and headed by Fred S. Hoffman (of Research and Development Associates), addressed the implications for nuclear policy of renewed emphasis on BMD. This Paper covers the same technologies and issues as these Defense Department studies. The ABM Treaty reached at SALT I[3] severely restricts the development, testing, and deployment of BMD systems. Though this Background Paper treats the strategic roles of missile defenses, including many of their arms control implications, it does not treat the vital international political implications of a major U.S. move to BMD.

Focused on directed-energy intercept of missiles in their boost phase, i.e., on "Star Wars" proper, this Paper does not analyze midcourse and reentry BMD systems or non-BMD applications of directed-energy weapons.[4] "Star Wars" efforts generally further concentrate on intercept of intercontinental ballistic missiles (ICBMs) rather than the related but somewhat different problems of intercept of submarine launched ballistic missiles (SLBMs) or intermediate-range ballistic missiles (IRBMs). This Paper is therefore not a substitute for a more complete treatment of the entire subject of BMD.[5] Moreover, BMD itself is only part of the larger subject of strategic defense, comprising defense against bombers and cruise missiles, civil defense, passive defense of military targets, anti-submarine warfare (ASW), and preemptive counterforce attack in addition to BMD.

[1] BMD is the most common of four roughly equivalent acronyms covering defense against nuclear ballistic missiles. Such defenses were formerly called anti-ballistic missile (ABM) systems, but this designation fell out of favor after the debate over and eventual demise of the Sentinel and Safeguard ABM systems in the late 1960's and early 1970's. BMD largely replaced ABM as the term of choice, but recently the more self-explanatory Defense Against Ballistic Missiles (DABM) has gained popularity. Within the Executive Branch, BMD efforts pursuant to President Reagan's so-called "Star Wars" speech are referred to as the Strategic Defense Initiative (SDI). Normally the term strategic defense comprehends other methods for limiting damage from nuclear attack besides BMD.

[2] The relevant portions of President Reagan's speech are reproduced in Appendix A.

[3] The ABM Treaty and related documents are reproduced in Appendix B.

[4] Appendix C describes briefly, but does not assess, other proposed military applications of directed-energy weapons.

[5] For a more complete treatment, see *Ballistic Missile Defense*, ed. Ashton B. Carter and David N. Schwartz (Brookings, 1984).

It is unusual for the President to express himself on, and for the Congress and public consequently to concern themselves with, long-term research and development. "Star Wars" is thus a somewhat unusual subject for a technology assessment intended for a public policy audience. It is in the nature of this subject that unknown or unspecified factors outweigh what is known or can be presented in concrete detail. Many of the technologies discussed in this Paper, and most certainly all of the schemes for fashioning a defense system from these technologies, are today only paper concepts. In the debate over the Safeguard ABM system a decade ago, or over basing modes for the MX missile in recent years, one could analyze in detail the technical properties of well-defined systems in engineering development. So vague and tentative are today's concepts for "Star Wars" BMD that a comparable level of analysis is impossible. Fashions and "front runners" are likely to change. Nonetheless, one is faced with assessing the concepts receiving attention today within the Executive Branch and which underlie the President's Strategic Defense Initiative. Fortunately, judgments deduced from generic properties of these concepts, which are unlikely to change, are sometimes telling.

This Paper is based on full access to classified information and studies performed for the Executive Branch. But it turns out that a fully adequate picture of this subject can be presented in unclassified form. One reason is that the important features of the directed-energy BMD concepts are based on well-known physics, and many have in fact been discussed for 20 years. The second reason is that at this early stage of conceptualization there is simply no point in (and little basis for) discussion at the detailed level where classified particulars make a difference. The properties of actual weapon systems in engineering development, by contrast, are normally and understandably classified.

The author and OTA wish to thank officials of the Army's Ballistic Missile Defense Systems Command (BMDSCOM), the Lawrence Livermore National Laboratory, the Los Alamos National Laboratory, the Defense Advanced Research Projects Agency (DARPA), the Sandia National Laboratory, the Air Force Weapons Laboratory (AFWL), the Office of the Secretary of Defense (OSD), and the Central Intelligence Agency (CIA) for their hospitality and cooperation. Many individuals aided the research for this Background Paper, though none shares the author's sole responsibility for errors of fact or judgment. The author and OTA wish especially to thank Hans Bethe, Richard Briggs, Al Carmichael, Albert Carnesale, Paul Chrzanowski, Robert Clem, Sidney D. Drell, Dick Fisher, John Gardner, Richard L. Garwin, Ed Gerry, Jack Kalish, Glenn A. Kent, Louis Marquet, Michael M. May, Tom Perdue, Theodore A. Postol, George Rathjens, Victor Reis, Jack Ruina, George Schneiter, David N. Schwartz, Robert Selden, Leon Sloss, Daryl Spreen, Robin Staffin, John Steinbruner, Sayre Stevens, Thomas Weaver, Stephen Weiner, and Wayne Winton.

This Background Paper contains information current as of January 1, 1984.

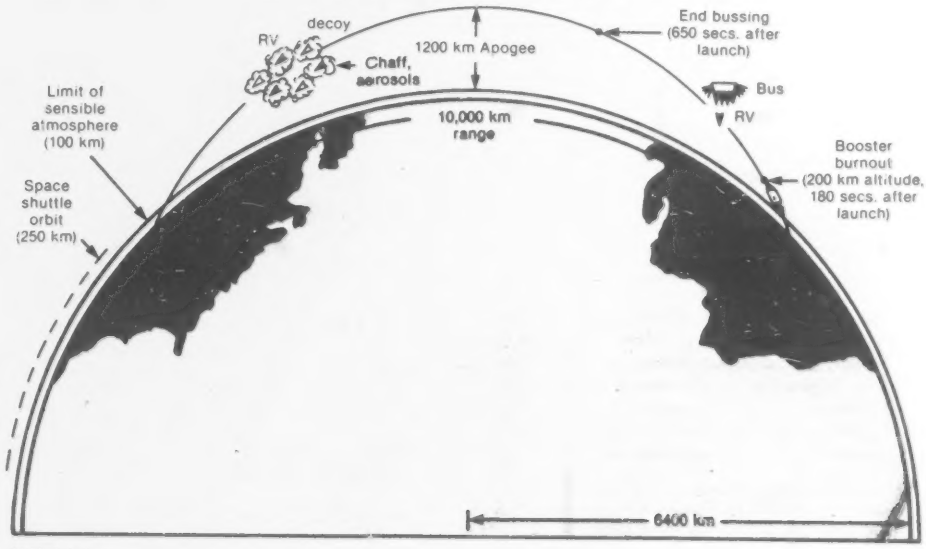
Section 2
BOOSTER CHARACTERISTICS

Intercept of ICBMs in their boost phase offers advantages and disadvantages relative to intercept of reentry vehicles (RVs) later in the trajectory. The boosters are fewer and generally more easily disrupted or destroyed than the RVs. Decoy boosters would have to match an ICBM's huge heat output, making this offensive tactic attractive only in certain circumstances. The disadvantages of boost phase intercept are that boost phase is only a few minutes long and comprises the earliest stage of an attack, and that sensing and intercept must be accomplished from outer space and over enemy territory.

Figure 2.1 shows an ordinary (minimum energy) trajectory of a hypothetical future Soviet ICBM that has been given, for illustration, the boost profile of the U.S. MX Peacekeeper. Pressure from a steam generator expells the missile from its storage cannister. Once clear of the cannister, the missile ignites its first stage motor. The first stage burns for about 55 seconds, burning out at an altitude of about 22 kilometers. The second stage also burns for 55 sec, burning out at 82 km. The third stage burns for 60 sec and carries the remainder of the missile to about 200 km, the altitude of the lowest earth orbiting satellites.

When the third stage is jettisoned at the end of the 3-minute boost phase, the remainder of the missile consists of the post-boost vehicle (PBV) or "bus" and its cargo of 10 reentry vehicles. At this point the bus and RVs are in ballistic free-fall flight to the United States. Even if they are disrupted in some way or destroyed, these objects or their debris will reenter the atmosphere over the United States. The last few seconds of third stage burn are crucial for giving the payload

Figure 2.1.—The Flight of a Hypothetical Future Soviet ICBM With the Booster Characteristics of the U.S. MX Peacekeeper, Drawn to Scale



SOURCE: Author

enough speed to reach the United States, so disruption of boost phase any time right up to burnout will cause the warheads to fall far short.

For the next 500 seconds or so after burnout—almost until it reaches apogee—the bus uses its thrusters to make small adjustments to its trajectory. After each adjustment, it releases an RV. RVs released on different trajectories continue on to different targets as multiple independently targeted reentry vehicles (MIRVs). Decoys and other penetration aids for helping the RVs escape defenses later in the trajectory are deployed during busing.

The bus itself is a target of declining value as it dispenses its RVs. Destroying it early in the deployment process would obviously be useful: the RVs not yet deployed from the bus would still arrive at the United States, but perhaps nowhere near their intended targets. If cities are the targets, relatively small aiming errors might be inconsequential. In any event, tracking the bus to allow some form of intercept requires a different type of sensor from that which tracks the booster for boost phase intercept, since the bus's thrusters are small and operate intermittently. Because of its small size, the bus (or at least critical elements of it) might be more easily hardened against directed-energy weapons than the booster. For all these reasons, the value of attempting bus intercept is very unclear, and it usually does not figure prominently in BMD discussions.

From apogee, the slowest point in their free-fall trajectory, the RVs and empty bus gain speed as they fall back to earth. RVs are more resistant to damage from directed-energy weapons than boosters, and they might be accompanied by many decoys. When these objects enter the upper atmosphere at about 100 km altitude somewhat over 2 minutes before impact, they begin to heat up, and the lighter objects slow down. Still lower, below 50 km altitude and less than a minute before impact, the objects undergo violent deceleration and the bus breaks up. The RVs, now glowing with heat, streak toward their targets at an angle of about 23 degrees to the horizontal.

The trajectory shape can be altered at the expense of payload (see Figure 2.2). A lofted trajectory takes longer but reenters faster, and a depressed trajectory can offer unfavorable viewing angles to defensive sensors late in the trajectory.

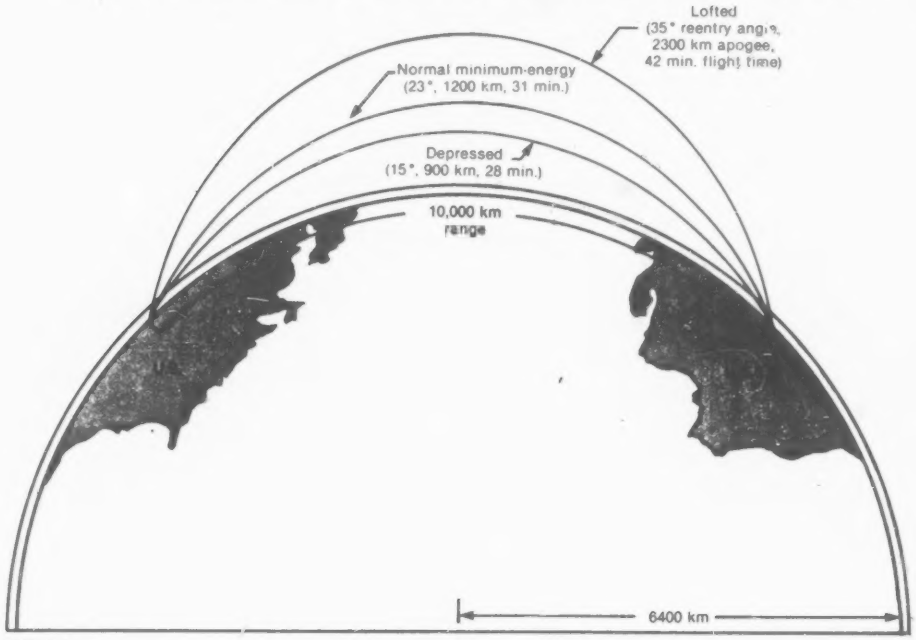
The most important trajectory variations from the point of view of boost phase intercept are variations in boost profile. Boosters like MX were designed with no regard for boost phase BMD, and optimizing their design gave rise to rather long boost times. But boost phase can be shortened--giving less time for boost phase weapons to act—and accomplished within the atmosphere—where certain directed-energy weapons cannot penetrate—with relatively little reduction in payload or increase in missile size. Fast burn is accomplished most easily with solid-fueled rockets. Liquid-fueled boosters like the Soviet SS-18s and SS-19s burn more slowly and burn out at higher altitudes. Thus while MX burns out at 200 km after 3 minutes of boost, the SS-18 burns out at 300-400 km after 5 minutes. The next generation of Soviet ICBMs will reportedly employ solid propellants.

Studies performed for the Defense Department[1] showed that with a 25 percent reduction in payload, a booster about the same size as MX could be built which would burn out in less than 1 minute at only 80 to 90 km, well within the sensible atmosphere. At 90 km the atmosphere is still too dense for extremely accurate RV deployment or for deployment of lightweight RV decoys and other penetration aids aimed at later defensive layers: these functions require an additional 10 to 15 seconds of precision deployment between 90 and 110 km. If the offense needs precision accuracy for some of its ICBMs but fears intercept during these additional few seconds of high-altitude operation, mounting one or two RVs on each of several "microbuses" instead of all the RVs on a single bus affords some protection. Each microbus would contain a simple guidance system only good enough to carry the RVs from upper stage burnout to 110 km. Instead of presenting one target above 90 km, therefore, such a booster would present several targets.

The United States is studying a "Midgetman" missile endorsed by the President's Commission on Strategic Forces (the Scowcroft Commission)

[1] "Short Burn Time ICBM Characteristic and Considerations," Martin Marietta Denver Aerospace, July 20, 1983 (UNCLASSIFIED).

Figure 2.2.—Normal (Minimum-Energy), Lofted, and Depressed ICBM Trajectories, Drawn to Scale



SOURCE: Author

with weight 15 to 25 percent that of MX and carrying one warhead. Midgetman's warhead and bus are combined in one hardened structure. Table 2.1 shows the characteristics of Midgetman variants designed to face a boost-phase intercept system. The fast-burn version burns out at 80 km after 50 secs of boost. With a 10 percent increase in weight, the fast-burn version can carry a substantial payload of penetration aids. A low-flight-profile version is intended to stay within the atmosphere until burnout, protecting it from some types of directed-energy weapon. In the hardened version, one gram of ablative or other shielding material has been applied to each square centimeter of the entire booster body (if the boost-phase intercept system did not begin operation until a minute or so after launch, the first stage might not have to be hardened). These small boosters are all estimated to cost $10 to $15 million per copy, assuming a buy of 1,000 boosters. Costs for the second and subsequent thousand would of course be substantially smaller. These costs are two to three times higher per RV than MX.

The Soviet ICBM arsenal today comprises about 1,400 boosters, more than two-thirds of them MIRVd. Most are slow-burning liquid-fueled boosters. The U.S. arsenal contains about 1,000 faster-burning solid-fueled Minuteman boosters, about half of them MIRVd. Both sides are adding solid boosters to their arsenals in the 1980's.

The geographic distribution of offensive boosters can also be important to space-based boost-phase defenses. The number of satellites required in a defensive constellation usually increases if all opposing ICBM silos are concentrated in one region and decreases if the silos are spread over

Table 2.1.—ICBM Booster Characteristics

	Gross weight (kg)	Length (m)	Width (m)	Type	Booster burnout time (seconds after launch)	Booster burnout altitude (km)	End bussing time (seconds after launch)	End bussing altitude (km)	Comments
SS-18	220,000[a]	35.0	3.0	2-stage liquid	~300	~400	—	—	—
MX Peacekeeper	89,000	21.3	2.3	3-stage solid	180	200	650	1,100	Carries 10 RVs on a single bus
MIRVd fast-burn booster	87,000	22.9	2.1	2-stage solid	50	90	60	110	Deploys several "microbuses" carrying RVs and decoys
Midgetman	19,000	12.1	1.5	2-stage solid	220	340	—	—	Carries one accurate RV
Midgetman fast-burn	20,000	13.8	1.5	2-stage solid	50	80	—	—	Carries one accurate RV
Midgetman fast-burn with midcourse penetration aids	22,000	14.3	1.5	2-stage solid	50	80	—	—	Carries one accurate RV plus decoys
Midgetman with low flight profile	25,000	13.4	1.5	1st stage solid, 2nd liquid	220	100	—	—	Carries one accurate RV
Hardened Midgetman	30,000	15.1	1.5	1st stage solid, 2nd liquid	220	320	—	—	Carries one accurate RV; entire booster covered with 1gm/cm² shielding
Pershing II	7,500	10.5	1.0	2-stage solid	100	—	—	—	—

wide land areas. (On the other hand, too much concentration allows defensive satellites to be focused on one region by choosing the orbits judiciously.) Soviet SS-18 ICBMs, their largest MIRVd missiles, are organized into 6 wings of about 50 missiles each, spread out over a large region of the U.S.S.R. U.S. Minuteman missiles are organized into 6 wings of about 150 missiles each. Figures 2.3 and 2.4 show the geographic distributions.

The capabilities of a hypothetical future U.S. BMD should be measured against the *future* and *potential* Soviet ICBM arsenal, not against today's arsenal. The future arsenal will differ due to the natural retirement of old ICBMs and introduction of new ones, and because the Soviets might well react with new and different deployments when they learn of any U.S. plans to deploy defenses. It is impossible to project Soviet deployments far into the future. A reasonable "baseline" estimate for the Soviet ICBM arsenal 15 to 20 years from now might assign them the same number of boosters they have today, but with burn characteristics similar to the U.S. solid-propellant MX. This Background Paper indicates where and how the effectiveness of a hypothetical U.S. defense depends on the nature of the offensive arsenal it faces. In addition to having shorter average burn times, future Soviet ICBMs could be more numerous, deployed less widely geographically, less highly MIRVd, hardened against intercept, and so on.

Section 3
DIRECTED ENERGY WEAPONS FOR BOOST-PHASE INTERCEPT

This section describes the entire set of "beam weapons" being considered in the United States today for boost-phase ICBM intercept. Though these weapons receive the most attention, the "kill mechanism" that destroys the booster is not necessarily the most important or technically challenging part of an overall defense system. The next section describes other essential elements of a boost-phase defense.

A revisit to this subject several years from now might well find a new family of directed energy concepts receiving attention. But for now the devices described in this section are the basis for assessments of the prospects for efficient boost-phase defense, in the Defense Department and elsewhere (fig. 3.1). Though some of these concepts are new, many have in fact existed in one form or another for more than twenty years.

Figure 3.1

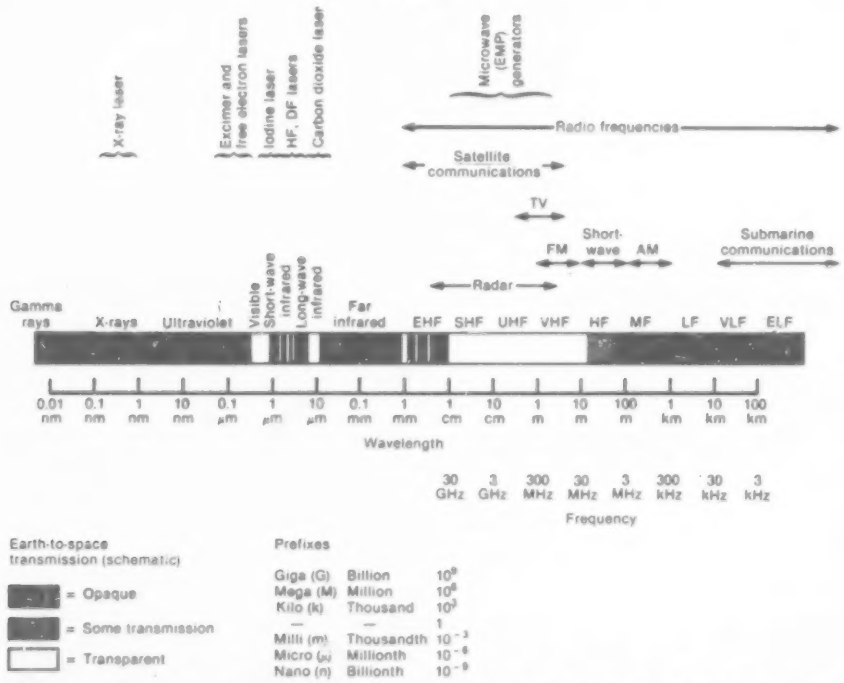

Figure 3.1 The electromagnetic spectrum, showing spectral regions of interest for directed energy BMD. Particle beams and kinetic energy weapons are not shown because their energy does not consist of electromagnetic radiation, but of atomic and macroscopic matter, respectively. Source: Author

For each concept this section attempts to work through, with some concreteness, the design of a hypothetical defensive system based on the concept. The resulting designs are *illustrative only;* no significance should be attached to precise numbers. Precision is simply not possible in the current state of technology and study of these concepts.

In all cases, the "current state of technology" (however this is defined in each case) is far from meeting the needs of truly efficient boost-phase intercept. The systems designed in this section illustrate the level to which technology would have to progress to be "in the ballpark." Much attention fastens on the gulf between the current state of technology and the ballpark requirements. This section does not emphasize such comparisons for several reasons. First, in some cases details of the precise status of U.S. research is classified. Second, and more importantly, quantitative comparisons (e.g., "A millionfold increase in brightness is required to fashion a weapon from today's laboratory device") can mislead unless accompanied by a deeper explanation of the technology; and the same quantitative measures are not appropriate for all technologies. Third, and most importantly, such comparisons imply that learning how to build the right device is tantamount to developing an efficient missile defense, which is far from true: equally crucial are design of a sensible system architecture, cost, survivability, resilience to countermeasures, and the myriad detailed limitations that do not turn up until later in development.

3.1 SPACE-BASED CHEMICAL LASERS: A FIRST EXAMPLE

This concept of directed energy weapon has been the one most frequently discussed in recent years for boost-phase ICBM intercept. For this reason (and not necessarily because it is the most plausible of all the concepts), it will be used to introduce certain features common to all the schemes that follow.

Making and Directing Laser Beams

A molecule stores energy in vibrations of its constituent atoms with respect to one another, in rotation of the molecule, and in the motions of the atomic electrons. The molecule sheds energy in the form of emitted light when it makes transitions from a higher-energy state to a lower-energy state. Lasing takes place when many molecules are in an upper state and few are in a lower state: one downward transition then stimulates others, which in turn stimulate yet more, and a cascade begins. The result is a powerful beam of light.

Energy must be supplied to the molecules to raise most of them to the upper state. This process is called pumping. In the case of the chemical lasers considered in this section, the pumping energy comes from the chemical reaction that makes the lasant molecules: hydrogen and fluorine react to form hydrogen fluoride (HF) molecules in an upper state. The other requirement for lasing—few molecules in the lower state—is satisfied simply by removing the molecules from the reaction chamber after they have made their transitions to the lower state and replacing them with freshly made upper state molecules. The pumping process is not perfect: not all the pumping energy ends up as laser light. The ratio of pumping energy in to laser energy out is called the efficiency of the laser.

Laser light is special in two respects: its frequency is precise, since all the light comes from the same transition in all the molecules; and the light waves from all the molecules emerge with crests and troughs aligned, since the waves are produced cooperatively. These special features make it possible to focus the laser energy with mirrors into narrow beams characterized by small divergence angles (see fig. 3.2). Nonetheless, there is a limit to the divergence angle that even a perfect laser with perfect mirrors can produce. The divergence angle (in radians) can be no smaller than about 1.2 times the wavelength of the light divided by the diameter of the mirror. Thus a laser with 1 micrometer (=1 micron)

38-036 O - 84 - 80

Figure 3.2

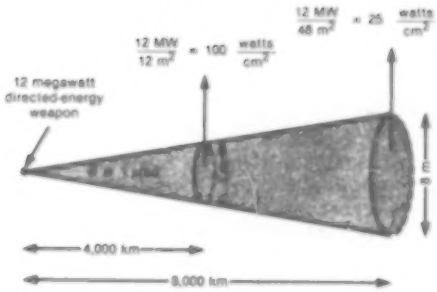

Figure 3.2 Basic power relationships for directed energy weapons. If the directed energy weapon has a divergence angle of 1 microradian, the spot size at a range of 4000 kilometers is 4 meters (12 feet). In this figure, the divergence angle is exaggerated about 1 million times. (For comparison of scale, the Earth's radius is about 6,400 km.) If the directed energy weapon emits 12 megawatts of power, a target within the spot at 4,000 km receives 100 watts on each square centimeter of its surface. (For comparison, 100 watts is the power of a lightbulb, and a typical commercial powerplant produces 1,000 megawatts). Since a watt of power equals one joule of energy per second this weapon would take 10 seconds to apply a kilojoule per square centimeter (1 KJ/cm²) to the target at 4,000 km range. Source: Author

wavelength projected with a 1 meter mirror could have at best a 1.2 microradian divergence angle, making a spot 1.2 meters wide at a range of 1,000 kilometers (refer to fig. 3.2).[1] This perfect performance is called the diffraction limit. Dividing the laser power output by the size of the cone into which it is directed (cone size is measured in units called steradians; a divergence angle of x radians results in a cone of size $\pi x^2/4$ steradians) yields the laser's "brightness," the basic measure of a weapon's lethality.

Destroying Boosters with Lasers

Assuming a high-energy laser with small divergence angle can be formed, stabilized so it does not wave about (jitter), and aimed accurately, what effect will it have on an ICBM booster? No clear answer to this question can be given without more study and testing. Estimates of the hardness achievable with future boosters are probably reliable within a factor of two or three, though estimates of the hardness of current Soviet boosters are probably reliable only to a factor of 10 or so.

Roughly speaking, laser light can damage boosters in two distinct ways. With moderate intensities and relatively long dwell times, the laser simply burns through the missile skin. This first mechanism is the relevant one for the chemical lasers described in this section. The second mechanism requires very high intensities but perhaps only one short pulse: the high intensity causes an explosion on and near the missile skin, and the shock from the explosion injures the booster. This mechanism, called impulse kill, is more complex than thermal kill and is less well understood. It will be discussed in the next section.

Bearing in mind the uncertainties in these estimates, especially the complex interaction of heating with the mechanical strains of boost, the following estimates are probably reliable: A solid-fueled booster can probably absorb without disruption up to about 10 kilojoules per square centimeter (kJ/cm²) on its skin if a modicum of care is taken in the booster's design to eliminate "Achilles' heels." This energy fluence would result from 1 second of illumination at 10 kilowatts per square centimeter (kw/cm²), since one watt equals one joule per second.[2] Applying ablative (heatshield) material to the skin can probably double or triple the lethal fluence required. Applying a mirrored reflective coating to the booster is probably not a good idea, since abrasion during boost could cause it to lose its lustre. Spinning the booster triples its hardness, since a given spot on the side of the booster is then only illuminated about a third of the time.[3] On the other

[1] The spot from a perfect laser with perfect mirrors would actually be brighter at the center than at the edges. The full angle subtended by this spot (the Airy disk from null to null in the diffraction pattern), is 2.4 times the wavelength divided by the mirror diameter, but most of the energy is in the central fourth of this area: hence the use in the text of the multiplier 1.2.

[2] The lethal fluence (in kJ/cm²) must accumulate over a relatively short time, so that the booster wall suffers a high rate of heating. Thus a flux of 30 watts/cm² would deposit 10 kJ/cm² in 330 sec of dwell time, but such a slow rate of heating would probably not damage the booster.

[3] It is possible that uniform heating around the circumference of the booster introduces lethal mechanisms distinct from those that apply to heating a single spot on the side of the booster. In that case, spinning the booster might not lengthen the required dwell time by the full amount dictated by geometry.

hand, currently deployed boosters, especially the large liquid Soviet SS-18s and SS-19s, might be vulnerable to 1 kJ/cm² or even less. These too could be hardened by applying heatshield material.

An Orbiting Chemical Laser Defense System

Consider a space-based BMD system comprised of 20-megawatt HF chemical lasers with 10 meter mirrors. The HF laser wavelength of 2.7 microns is attenuated as it propagates down into the atmosphere, but most of the light gets down to 10 km or so altitude. Deeper penetration is not really needed, since the laser would probably not be ready to attack ICBMs until after they had climbed to this altitude, and in any event clouds could obscure the booster below about 10 km. (Substituting the heavier and more expensive deuterium, an isotope of hydrogen, to make a DF laser at 3.8 micron wavelength would alleviate attenuation, but the longer wavelength would require larger mirrors.)

A perfect 10 meter mirror with a perfect HF laser beam yields 0.32 microradian divergence angle. The spot from the laser would be 1.3 meters (4.0 ft) in diameter at 4 megameters (4,000 kilometers) range. 20 megawatts distributed evenly over this spot would be an energy flux of 1.5 kw/cm². The spot would need to dwell on the target for 6.6 seconds to deposit the nominal lethal fluence of 10 kJ/cm². At 2 megameters (Mm) range, booster destruction would require only a fourth of this time, or 1.7 seconds of illumination. Since light takes about a hundredth of a second to travel 4 megameters and the booster is traveling a few kilometers per second, the booster moves about 50 meters in the time it takes the laser light to reach it. The laser beam must therefore lead the target by this distance.

The next step is to choose orbits for the satellites so that the U.S.S.R.'s ICBM silos are covered at all times and so that there are enough satellites overhead to handle all 1,400 of the present Soviet booster population. Equatorial orbits (fig. 3.3) give no coverage of the northern latitudes where Soviet ICBMs are deployed. Polar orbits give good coverage of northern latitudes but concentrate satellites wastefully at the poles where there are no ICBMs. The optimum constellation consists

Figure 3.3

Figure 3.3 Designing a constellation of directed energy weapon satellites for optimum coverage of Soviet ICBM fields. Equatorial orbits (a) give no coverage of northern latitudes. Polar orbits (b) concentrate coverage at the north pole. Inclined orbits (c) are more economical. Slight additional economies are possible in some cases with further elaboration of the constellation design. Source: Author

of a number of orbital planes inclined about 70° to the equator, each containing several satellites.

The shorter the lethal range of the directed energy weapon, the lower and more numerous the satellites must be. For instance, with a lethal range of 3 Mm, 5 planes containing 8 satellites each, or a total of 40 satellites, are needed to ensure that Soviet boosters exiting Soviet airspace would be within lethal range of one satellite. If the lethal range is increased to 6 Mm, only 3 planes of 5 satellites each are needed. This dependence of constellation size on weapon range is displayed in figure 3.4. (It is possible to adjust these numbers a bit by using slightly elliptical orbits with apogees over the northern hemisphere, adjusting inclinations and phasing, etc.). In the present example, requiring that at least one HF laser be no further than 4 Mm from each Soviet ICBM site at all times (corresponding to no longer than 6.6 seconds dwell time per booster) results in the illustrative constellation of 32 orbital positions shown in figure 3.5.

Since the 1,400 Soviet boosters currently deployed are spread out over most of the Soviet Union, perhaps 3 of the 32 orbital positions would be over or near the Soviet Union at a time, able to make efficient intercepts. That is, only one in 11 deployed U.S. battle stations would participate in a defensive engagement. The ratio of the total number of battle stations on orbit to the number in position to participate in a defensive engagement is called the absentee ratio. The inevitable waste reflected in the absentee ratio—

Figure 3.4 The number of satellites needed in a constellation to ensure that at least one satellite is over each Soviet ICBM field at all times depends on the effective range of the directed energy weapon. For every one defensive weapon required overhead a Soviet ICBM field to defend against a rapid Soviet attack, an entire constellation must be maintained on orbit. Since there are many Soviet ICBM fields distributed over much of the Soviet landmass, more than one satellite in each constellation would be in position to participate in a defensive engagement. The ratio of the number of satellites in the constellation to the number over or within range of Soviet ICBM fields is called the absentee ratio. If all Soviet ICBMs were deployed in one relatively small region of the U.S.S.R., the absentee ratio would be the same as the number of satellites in the constellation. Source: Author

Each of the four orbital planes consists of eight positions spaced 45° apart around the circle. In the example given in the text, five chemical laser battle stations are clustered at each point shown in this figure, for a total of 32 x 5 = 160 battle stations. Source: Author

usually on the order of 10—offsets an oft-cited theoretical advantage of boost-phase intercept, namely, that intercepting one booster saves buying 10 interceptors for the booster's 10 RVs. On the other hand, coverage of the U.S.S.R.'s ICBM fields automatically gives good coverage of essentially all submarine deployment areas. Obviously the absentee ratio would be 32—the full constellation size—and not 32/3 = 10.7 if Soviet ICBM silos were not spread out so widely over Soviet territory but were deployed over a third or less of the Soviet landmass, so that only one of the 32 U.S. satellites was within range.

Three of the earlier described laser satellites in position over the Soviet ICBM fields are not enough to intercept 1,400 boosters if all or most of the boosters are launched simultaneously. Each satellite can only handle a few boosters because it must dwell for a time on each one. The time a chemical laser must devote to each booster depends on the satellite's position at the moment of attack—6.6 seconds for 4 Mm range, 1.7 seconds for 2 Mm range, etc. Taking 2 Mm as an average range for the 32-satellite constellation (hoping the Soviets do not choose a moment when most of the U.S. satellites are farther than 2 Mm from the ICBM flyout corridors to launch all their boosters simultaneously), a laser must devote an average of 1.7 seconds to each booster.

If the boosters in the future Soviet arsenal resemble the U.S. MX, and the defense waits 30 seconds or so to confirm warning and to wait for the boosters to climb to an altitude where the HF laser can reach, each booster is accessible for 150 seconds of its 180 second burn time. Each laser can therefore handle no more than 90 boosters, even with instant slewing of the beam from target to target. If 1,400 Soviet boosters were launched simultaneously, (1,400)/(90) ≅ 15 lasers would be needed in position, for a worldwide total (multiplying by the absentee ratio) of (10.7) × (15) = 160 satellites.

If the Soviets doubled their arsenal to 2,800 boosters, the United States would need to deploy another 160 satellites, possibly an uncomfortable cost trade for the United States.

What is worse, if the Soviets deployed 1,400 missiles in a *single region* of the U.S.S.R. (at a U.S.-estimated cost of $21 billion for Midgetman-like ICBMs; see section 2 above), the US would have to build, launch, and maintain on orbit an additional (32) × (1400)/(90) ≅ 500 lasers plus their fuel and support equipment.

If Soviet boosters were covered with shielding material and spun during flight to achieve an effective hardness of, say, 60 kJ/cm², a laser would have to devote 10 seconds to each booster at 2 Mm range, requiring a sixfold increase in the number of satellites, to 960. Alternatively, the average range of each engagement could be reduced to keep the dwell time at 1.7 seconds, with corresponding increase in constellation density (fig. 3.4). Either way, the number of U.S. satellites would grow to nearly the number of Soviet boosters intercepted.

Table 3.1.—Variation of the Number of Chemical Laser Battle Stations Needed to Handle a Simultaneous Launch of Soviet ICBMs, Depending on Characteristics of the Soviet Arsenal and the U.S. Laser Defense

Departure from baseline	Number of Soviet boosters	Booster characteristics	Geographic distribution	Hardness (kJ/cm²)	Laser power (MW) and aperture diameter (m)	Approximate number of battle stations needed
Baseline	1,400	MX-like	Current Soviet	10	20/10	160
Booster number	2,800	MX-like	Current Soviet	10	20/10	320
Deployment geography	1,400	MX-like	One region	10	20/10	500
Booster hardness	1,400	MX-like	Current Soviet	60	20/10	960
Laser brightness	1,400	MX-like	Current Soviet	10	80/50 (100 times brighter)	20-30
Booster burn time	1,400	Fast-burn	Current Soviet	10	20/10	800-1,600
Booster burn time	1,400	SS-18-like	Current Soviet	10	20/10	90

SOURCE: Author.

If the United States developed a battle station 100 times brighter (using, say, a 80 MW laser with an effective mirror diameter of 50 meters), a few lasers overhead (20 to 30 total worldwide) could easily handle an attack of 1400 boosters hardened to 10 kJ/cm². If the boosters were hardened to 60 kJ/cm², over 100 such lasers would be needed.

Deployment by the Soviets of 1400 fast-burn boosters would give the U.S. lasers just 20 to 40 seconds, rather than 200 seconds, to destroy all the boosters. The U.S. constellation would consequently need to grow by a factor 5 to 10, to 800 to 1600 satellites!

Table 3.1 summarizes how the size of the defensive deployment varies with the parameters assumed.

Requirements for a Chemical Laser Defense

Figure 3.6 displays the performance of various hypothetical HF lasers. Keeping the size of the battle station constellation down to a hundred rather than several hundred satellites means lethal ranges of at least 4 Mm with illumination times less than about 1 second, assuming the defense must be capable of intercepting 1,000 to 2,000 Soviet boosters with launches timed to keep the boosters as far from the U.S. lasers as possible. Further assuming Soviet booster hardening to at least 10 kJ/cm² results in a requirement for chemical lasers considerably brighter than the 20 MW, 10-meter laser described above. A hundredfold increase in brightness would be achieved by a laser with power 80 MW and effective mirror diameter 50 meters.

Such a laser would be about 10 million times brighter than the carbon dioxide laser on the Air Force's Airborne Laser Laboratory. The current Alpha laser program of the Defense Advanced Research Projects Agency (DARPA) aims at a construction of an HF laser of just a few megawatts and built only for ground operation. Nonetheless, there is no fundamental technical reason why extremely bright chemical lasers cannot be built. In theory, several lasers can be operated together so that the brightness of the resulting beam increases with the square of the number

Figure 3.6

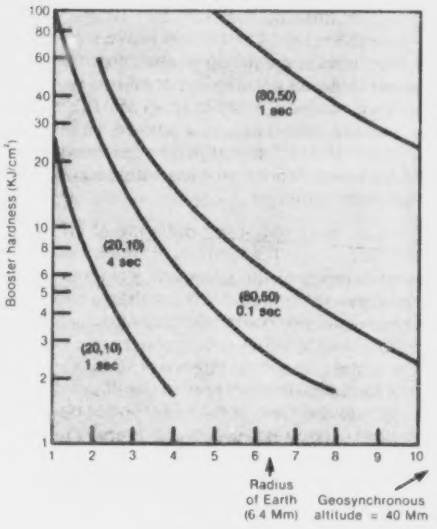

Figure 3.6 Lethal range versus booster hardness for HF chemical lasers of various sizes and dwell times. The labels on the curves have the format (laser power in megawatts, mirror diameter in meters) followed by the amount of time the laser devotes to destroying each booster. Source: Author

of lasers: 10 lasers combined in this way would produce a beam 100 times brighter than each individual laser. The trick is to arrange for the troughs and crests of the light waves from all the lasers to coincide. This theoretical prospect is unlikely to be realized with HF lasers, since their light is actually emitted at several wavelengths and with shifting patterns of crests and troughs.

To yield diffraction-limited divergence, the mirror surface must be machined to within a fraction of a wavelength of its ideal design shape over its entire surface. Since the mirror is over a million wavelengths across, avoiding small figure errors is a severe requirement. A number of small mirrors can obviously combine to produce one large optical surface if their positions are all aligned to within a fraction of a wavelength. The

mirrors must maintain perfect surface shape in the face of heating from the laser beam, vibration from the chemical reaction powering the laser, and vibrations set up in the mirror as it is slewed. Substantial hardening of mirrors to radiation from nuclear bursts in space and to the x-ray laser (described below) would be a challenging task. The 2.5-meter diameter mirror on NASA's Space Telescope was produced without these constraints.

An extremely optimistic outcome of HF laser technology—near the theoretical limit for converting the energy of the chemical reactants to laser energy—would require more than a kilogram of chemicals on board the satellite for every megajoule radiated. A spot diameter of 2 meters at the target and a lethal fluence of 10 kJ/cm² over this area results in an energy expenditure of 300 MJ per booster. Destroying 1,000 Soviet boosters therefore requires, reckoning very crudely, 300,000 kg of chemicals in position over the Soviet ICBM field, or perhaps 10 million kg on orbit worldwide. The space shuttle can carry a payload of about 15,000 kg to the orbits where the satellite battle stations would be deployed. About 670 shuttle loads would therefore be needed for chemicals, with perhaps another half as many for the spacecraft structures, the lasers and mirrors, construction and deployment equipment, and sensors. 1,000 shuttle missions for every 1,000 Soviet boosters (perhaps Midgetmen) deployed in reaction to the U.S. defense is an impractical competition for the United States. Use of HF chemical lasers for BMD therefore requires remarkably cheap heavy-lift space launch capability in the United States.

The remaining components of the chemical laser defense system—sensors, aiming and pointing technology, and communications— are for the most part generic to all directed energy weapons and are discussed in section 4. Section 5 presents countermeasures the Soviets might take to offset or nullify a chemical laser defense.

3.2 GROUND-BASED LASERS WITH SPACE-BASED MIRRORS

A slight variant of the previous concept puts the laser on the ground and mirrors in space, reflecting the light back down toward Earth to attack ascending boosters. This scheme avoids placing the laser and its power supply in space, though mirrors, aiming equipment, and sensors remain. The excimer and free-electron lasers considered for this scheme are in fact likely to be rather cumbersome, so ground basing them might be the only practical way to use them for BMD. The lasers would emit at visible or ultraviolet wavelengths about ten times shorter than the near-infrared wavelengths of the HF and DF chemical lasers in the space-based concept. Shorter wavelengths permit use of smaller (though more finely machined) mirrors. The high power available with ground basing suggests at least the possibility of impulse rather than thermal kill of boosters.

The term excimer is a contraction of "excited dimer." A dimer is a molecule consisting of two atoms. The dimers considered for these lasers contain an atom of noble gas and a halogen atom, making dimers like xenon fluoride (XeF), xenon chloride (XeCl), and krypton fluoride (KrF). The laser light comes from dimers in an excited upper state decaying to a lower state, just like in the HF laser. Excimer lasers tend to emit light in pulses rather than in a continuous wave. The population of upper-state molecules is provided by pumping with electric discharges in a rather complicated process. The population of lower-state molecules remains small because the lower-state dimer is unstable and quickly breaks up into its two constituent atoms. The pumping process for excimer lasers is inefficient, so only a small fraction of the energy put into the laser in the electric discharge emerges as laser light. Powerful excimer lasers would therefore be large and would need to vent large amounts of wasted energy; these characteristics make them unsuitable for space basing. Development of excimer lasers is at an early stage, and no excimer lasers exist with anything remotely approaching the characteristics needed for this boost phase intercept concept.

Figure 3.7

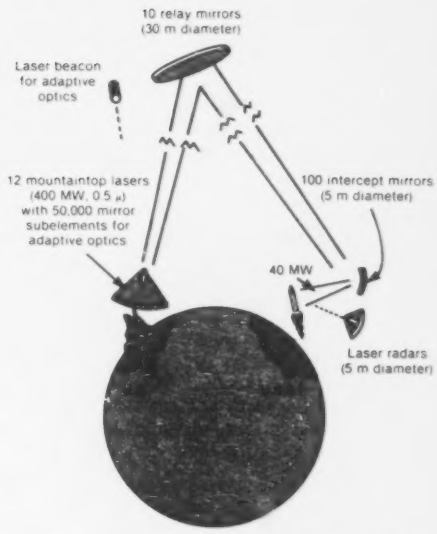

Figure 3.7 Illustrative configuration of ground-based excimer or free-electron laser and space-based mirrors for thermal kill of Soviet ICBM boosters. Source: Author

Power outputs achieved in the laboratory are still several orders of magnitude less than the average power needed for thermal kill, and the energy achieved in a single pulse is much smaller than the single-pulse energies needed for impulse kill.

The working of a free-electron laser (FEL) is more complicated.[4] As the name suggests, the light-emitter (lasant) is free electrons emitted from a particle accelerator. Pumping therefore originates in the electrical source powering the accelerator. The free electrons from the accelerator are directed into a tube called the wiggler that has magnets positioned along its length. The magnets cause the electrons to wiggle back and forth as they transit the tube. As they wiggle, the electrons emit some of their energy as light. The presence of light from one electron causes others to emit in the usual cooperative manner of a laser, and a cascade begins. By adjusting the positions of the magnets and the energy of the electrons, the wavelength of the light can be tuned to any value desired. The only advantage of the FEL over excimer lasers is the high efficiency that can (theoretically) be obtained with the former. It has been suggested that it might even be possible to position FELs in space like HF chemical lasers. FEL operation at visible wavelengths is in its infancy, and the experimental devices used are many millions of times less powerful than those required in this BMD.

The BMD scheme calls for a large ground based excimer or free electron laser, relay mirrors at high altitude to carry the laser beam around the curve of the Earth, and intercept mirrors to focus the beams on individual boosters (fig. 3.7). The characteristics of a nominal system for thermal booster kill are easily ascertained. Suppose first that there are enough intercept mirrors so that the average range from mirror to booster is 4 Mm, and suppose the Soviet boosters are destroyed with 10 kJ/cm² deposited on a spot as small as several centimeters wide. Assume the excimer or free electron laser operates at about 0.5 microns, in the visible band. Then a 5 m intercept mirror will produce a spot 50 cm wide at 4 Mm range. If a half second of the main laser beam is devoted to each booster, then the required 10 kJ/cm² will be accumulated if the power reflected from each intercept mirror is 40 MW.

Only about a tenth of the power emitted by the ground based laser in the United States would be focused on the booster over the U.S.S.R. The remainder would be lost in transit through the atmosphere and in reflection from the two mirrors. Thus a 400 MW laser is required.

Passage through the atmosphere poses a number of problems for the primary laser beam. The most important source of interference is turbulence in the air, causing different parts of the laser beam to pass through different optical environments when exiting the atmosphere. Each part of the beam suffers a slightly different disruption, and the beam that emerges does not have the

[4]See Charles A. Brau, "Free Electron Laser: A Review," *Laser Focus*, March 1981; *Physics Today*, December 1983, p.17.

orderly arrangement of crests and troughs needed for diffraction-limited focusing from the intercept mirror. Without compensation for atmospheric turbulence, the ground-based laser scheme is completely impractical. Fortunately, the pattern of turbulence within the laser beam, though constantly changing, remains the same for periods of a few milliseconds. Since it takes only 0.1 millisecond for light to make a round trip through the atmosphere, the effect of turbulence on the laser beam can be compensated for with the following technique, called adaptive optics: A low-power laser beacon is positioned near the relay mirror. A sensor on the ground observes the distortion of the beacon beam as it passes through the atmosphere. The beam from the ground-based laser is then predistorted in just such a way that its passage through the same column of air transited by the beacon beam re-forms it into an undistorted beam.

Figure 3.7 shows the many components required by the ground-based laser concept. Since each Soviet booster requires 0.5 sec of beam at some time during its 200 sec. boost phase, four beams would be needed to handle 1,400 Soviet boosters launched simultaneously (assuming no retargeting delays). The lasers should be deployed on mountain tops to make atmospheric effects manageable, and enough should be deployed that at least four sites are always clear of cloud cover. The mirror on the ground would need to be tens of meters across and divided into tens of thousands of individually adjustable segments for predistortion of the wavefront. Each relay mirror would need to be accompanied by a beacon. Four large interception mirrors would be needed within 4 Mm of each Soviet ICBM flyout corridor, giving a worldwide constellation of a hundred or so.

The small laser wavelength means that all mirrors must be more finely machined than the mirrors for the chemical laser and can tolerate smaller vibrations and stresses due to heating from the laser beam. The small wavelength also results in a spot 10 times smaller at the target than the spot from a chemical laser beam at the same range. This small spot requires pointing accuracy ten times finer. Perhaps most important of all, the plume from the booster motor is too large to serve as target for such a narrow beam. Some way of seeing the actual missile body against the background of the plume is needed for the short-wavelength laser schemes (and for some configurations of chemical lasers). One answer to this problem, described in section 4 below, is to position near each intercept mirror a low-power laser and a telescope (a laser radar or ladar): the laser illuminates the booster and the telescope observes the reflected laser light, directing the pointing of the intercept mirror. The ladar telescope must have a mirror as large as the intercept mirror, since it must be able to "see" a spot as small as that made by the beam.

A single immense laser pulse that deposits 10 kJ/cm² in a very short time—millionths of a second rather than a second— might cause impulse kill rather than thermal kill. In impulse kill, the laser pulse vaporizes a small layer of the booster skin and surrounding air. The superheated gases then expand explosively, sending an impulsive shockwave into the booster. A strong enough shockwave might cause the booster skin to tear. The advantage of this kill mechanism is that it would be very difficult to protect boosters from it. The disadvantages are that impulse kill requires prodigious laser pulses and mirrors that can withstand them, and that the mechanism is poorly understood and depends on myriad factors like the altitude of the booster at the moment it is attacked.

3.3 NUCLEAR BOMB-PUMPED X-RAY LASERS: ORBITAL AND POP-UP SYSTEMS

The U.S. Government has revealed efforts at its weapon laboratories to use the energy of a nuclear weapon to power a directed beam of x-rays. Such devices are said to constitute a "third generation" of nuclear weapons, the first two generations being the atomic (fission) and hydrogen

(fusion) bombs. Each succeeding generation represented a thousandfold increase in destructive energy, from a ton of high explosive to a kiloton fission weapon to a megaton fusion weapon. The third generation weapon uses the same amount of energy as the fusion weapon, but directs much of that energy toward the target rather than allowing it to escape in all directions. At the target, therefore, the energy received is much greater than the energy that would be received from a hydrogen bomb at the same range.

X rays lie just beyond ultraviolet light on the electromagnetic spectrum and have wavelengths about a thousand times smaller than visible light (see fig. 3.1). Compared to the infrared, visible, and ultraviolet lasers in the previous sections, the x-ray laser produces much more energy from its bomb pump, but the energy is spread out over a larger cone. The lethal ranges for boosters turn out to be roughly comparable for all these types of directed-energy device. Obviously the x-ray laser delivers all its energy in one pulse, so there is no question of dwell time on the target. Very short-wavelength x-rays penetrate some distance into matter (witness dental and medical x-rays), but the longer-wavelength x-rays produced by a laser device do not penetrate very far into matter or into the atmosphere.

Orbiting and ground-based "pop-up" systems have been proposed as ways to make use of the x-ray laser for boost phase BMD. Both of these schemes have attractive features but also serious drawbacks. It could well be that the x-ray laser device, if a powerful one can eventually be built, will be more useful in other strategic roles than boost-phase BMD.

X-Ray Lasers

Little has been revealed about the characteristics of the bomb-pumped x-ray laser being studied by the United States (the so-called Excalibur device), but some general information can be deduced from the laws of physics and, to a lesser extent, from the scientific literature here and in the Soviet Union.[5]

Figure 3.8

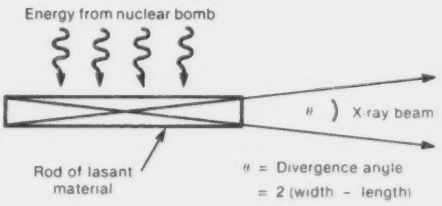

Figure 3.8 In an x-ray laser, a rod of lasant material is pumped to upper energy states by a nuclear bomb. Those cascades of downward transitions that travel lengthwise build up more energy than sideways-going cascades. As a result, most of the energy emerges from the ends of the rod into a cone with divergence angle equal to twice the rod width divided by its length. Source: Author

The pumping source for the x-ray laser is a nuclear bomb. The radiant heat of the bomb raises electrons to upper energy levels in atoms of lasant material positioned near the detonation (the chemical nature of the lasant material has not been revealed). As the electrons fall back again to lower levels, it can happen that for a moment many atoms are in a given upper level and few in a lower level; this is the necessary condition for lasing from the upper level to the lower level. The wavelength of the emitted x-ray is determined by the energy levels involved. The wavelength of the laser under study in the United States is classified. We will use a round number of 1 nm.

Since x-rays are not back-reflected by any kind of mirror, there is no way to direct the x-rays into a beam with optics like the visible and infrared lasers. Nonetheless, some direction can be given to the laser energy by forming the lasant material into a long rod. Recall that a laser beam builds up when light from one lasant atom stimulates the upper-to-lower-level transition in another atom, which stimulates a third, and so on. The result is a cascade of light heading in same direction as the light from the original atom. The light pulse gets stronger and stronger as it traverses the lasant medium stimulating more and more transitions. In a long rod of lasant material, cascades that get started heading lengthwise down the rod are highly amplified by the time they leave the rod, whereas sideways-going cascades remain small. The result is that most of the laser energy

emerges as a beam aligned along the rod axis (fig. 3.8).

The projected capabilities of the x-ray lasers being studied in the U.S. are classified; but it is fairly easy to determine the upper limit to how powerful such a laser could possibly be. Whether R&D will succeed in making such a perfect laser cannot be said. But it will become clear that something very close to the perfect laser is required for boost phase intercept, though a less successful development would still yield a potent antisatellite weapon.

A 1-megaton nuclear weapon releases about 4 billion megajoules of energy. By surrounding the bomb with lasant rods, most of this energy can be harnessed to pump the laser. Since the pumping mechanism for the x-ray laser is rather disorganized and wasteful, like the pumping mechanism for excimer lasers, at most a few percent of the bomb energy can be expected to end up in the laser beam.

The resulting 100 million megajoules or less of laser energy emerges from the rods into cones with relatively large divergence angle. It is easy to see why this divergence angle is much larger than the divergence angle obtained with the mirror-directed lasers treated in the previous section. The divergence angle is determined by the ratio of the width of the rod to its length, as in figure 3.8. A practical length for a rod is no more than about 5 meters. Making the rod thinner decreases the divergence angle, but beyond a certain point no further narrowing of the beam cone is possible. The limit arises from diffraction, just as with the infrared and visible lasers: the divergence angle of light emitted from an aperture (mirror, rod tip, or anywhere else) cannot be less than about 1.2 times the wavelength of the light divided by the diameter of the aperture. A very narrow rod therefore actually aggravates diffraction and produces a wide cone. Making the rod thinner results in no further narrowing of the beam when (1.2) (wavelength)/(rod width) $\cong$ (2) (rod width)/(rod length). For an x-ray wavelength of 1 nm and a rod length of 5 meters, this equation yields an optimum rod width of 0.06 mm and a minimum achievable (diffraction-limited) divergence angle of 20 microradians.

A 1-megaton bomb-pumped x-ray laser can therefore deposit no more than about 100 million megajoules into a cone no narrower than about 20 microradians. The x-ray pulse from detonating such a perfect laser would deposit about 300 kJ/cm^2 over a spot 200 meters wide at 10 Mm range.

Interaction of X-rays with Matter

X-rays of 1 nm wavelength do not penetrate very far into matter: all the energy from such a laser would be absorbed in the first fraction of a millimeter of the aluminum skin of a missile. This paper-thin layer would explode, sending a shockwave through the missile. Thus the x-ray laser works by impluse kill.

Another consequence of the opacity of matter to x-rays is that the laser beam would not propagate very far into the atmosphere. The altitude to which the beam would penetrate depends on the precise wavelength, which is classified. For the nominal 1 nm wavelength described above, boosters below about 100 km would be quite safe from attack. If the wavelength were much shorter, the x-rays would penetrate lower, reaching perhaps 60 km altitude or so. In what follows, it will be assumed that boosters are safe from x-ray laser attack below about 80 km.

One last consequence of the physics of x-ray interaction with matter is noteworthy. When an atom of matter absorbs an x-ray, it emits an electron. As x-rays are absorbed, it becomes harder and harder to remove successive electrons. Finally further x-rays cannot remove further electrons, and the matter becomes transparent. This phenomenon, called bleaching, means that a strong x-ray laser beam can force its way through a column of air by bleaching the column, but a weak laser beam is completely absorbed. An x-ray laser in the atmosphere might therefore be able to attack an object in space because the beam is intense enough in the vicinity of the laser to bleach the air, whereas an x-ray laser in space could not attack objects within the atmosphere. This fact bodes ill for defensive space-based x-ray lasers attacked by similar lasers (or

even weaker ones) launched from the ground by the offense.

As with visible and infrared lasers, the lethality of an x-ray laser is subject to large uncertainties. The proper order of magnitude for the amount of x-ray energy per square centimeter that needs to be deposited on the side of a booster to damage it can be estimated fairly easily. But the actual hardness of a booster would depend on many design details in a way that is not fully understood at this time. A simple calculation[6] indicates that 20 kJ/cm² is a reasonable number to take for the hardness of a booster. This is about the same as for impulse kill by visible laser. An RV would be harder, and a satellite softer.

Orbital Defense Concept

The "perfect" x-ray laser whose characteristics were deduced above would be capable of intercepting a booster from geosynchronous orbit 40,000 km above the Earth. One laser would be needed for each Soviet booster. At lower altitudes, the rods surrounding the bomb could be gathered into several bundles and each bundle aimed at a different booster. At these lower altitudes, though, the absentee problem means that roughly one x-ray laser device would still need to be placed in orbit for each Soviet booster. Though the x-ray lasers are small and light compared to a chemical laser, the cost tradeoff involved in launching a new laser every time the Soviets deploy a new ICBM is obviously not a tolerable one for the United States.

The x-ray laser can attack the boosters after they have left the protective atmosphere but before burnout. Simultaneous launch of all Soviet boosters is not a problem for x-ray lasers in the way it is a problem for chemical lasers that must dwell on each target before passing on to the next. Fast-burn boosters are likewise not a crippling problem for an orbiting x-ray laser system *unless* they burn out before they leave the atmosphere. Other countermeasures, most notably the vulnerability of U.S. orbital x-ray lasers to Soviet x-ray lasers, are treated in section 5.

Pop-Up Defense Concept

The pop-up concept represents an attempt to avoid the one-laser-per-booster cost exchange and the vulnerability associated with basing the lasers in space (though crucial sensors remain space-based even in the pop-up scheme). The small size and light weight of the bomb-pumped lasers makes it possible to consider basing them on the ground and launching them into space upon warning of Soviet booster launch.

Figure 3.9 shows why basing the pop-up lasers in the United States is not practical. During the 200 seconds or so of burn time of a Soviet MX-

Figure 3.9 X-ray lasers launched from the United States on warning of Soviet ICBM launch would have to climb at least as high as the line of fire shown in the figure within three minutes to intercept an MX-like Soviet ICBM. Such a huge fast-acceleration defensive booster would be many times larger than the Saturn V that took astronauts to the moon.
Source: Author

[6]A mallet or soft hammer blow applies an impulse per unit area of about 10 ktaps (0.5 kg hammer head, 5 m/sec striking velocity, 3 cm radius contact area; 1 tap = 1 dyne-sec/cm²). To apply an impulse of this strength to the entire side of an ICBM booster requires a fluence F, whose order of magnitude can be estimated as follows: The cold mass absorption length (a) for 1nm x-rays is about 0.5 milligrams/cm². If all the energy absorbed by the paper-thin absorbing layer were converted to kinetic energy, the boil-off velocity would be $(F/a)^{1/2}$, meaning an impulse per unit area of order $(Fa)^{1/2}$. 10 ktaps is therefore produced if F = 20 kJ/cm².

In reality, not all the deposited energy couples to the booster in this way. A more careful calculation of this lessened coupling has been performed by Hans Bethe (private communication).

33-698 O - 84 - 5 : QL 3

like ICBM, the U.S.-based pop-up lasers would have to climb high enough to see the Soviet boosters over the Earth's horizon and have a line-of-fire unobstructed by the absorbing atmosphere. Climbing so high so fast requires a booster for the x-ray lasers that is many thousands of times larger than the Saturn V rocket that carried U.S. astronauts to the Moon.

If the British Government allowed the U.S. Government to base x-ray lasers in the United Kingdom, the lasers would be separated from Soviet ICBM silos by only 45 degrees of arc rather than 90 degrees as with U.S. basing. Even so, popping up to attack an MX-like Soviet booster would require an enormous fast-burn booster for the x-ray laser and would put it into position to attack the Soviet booster only seconds before burnout. If the Soviets depressed the trajectory or shortened the burn time of the offensive booster very slightly, or if the United States suffered any delay whatsoever in launching the defensive boosters after Soviet launch (instantaneous warning), this hypothetical U.K.-based system would be useless.

A final possibility would be launch of defensive lasers from submarines stationed immediately off Soviet coasts—in the Kara Sea or Sea of Okhotsk, separated from Soviet silos by about 30 degrees of arc—on SLBM-sized fast-burn boosters. With instantaneous warning, a sea-based laser might be able to climb to firing position a few seconds before burnout of a Soviet MX-like ICBM and would enjoy almost an entire minute of visibility to a slow-burning, high-burnout-altitude booster like the SS-18. Because of the short range, each bomb-pumped laser of the perfect design described above could attack many (over 100) boosters using many individual lasing rods. Such efficiency could well be essential, since a submarine cannot launch all its missiles simultaneously and might only be able to fire one defensive missile in the required few seconds. If the MX-like Soviet boosters were flown on slightly depressed trajections, if warning were not communicated to the submerged submarine promptly, if a human decision to launch defensive missiles were required, or if the Soviets deployed boosters that burned faster than MX, the sub-launched system would be nullified. Last, submarine patrol very near to Soviet shores suggests the possibility of attacking the submarine with shore-based nuclear missiles as soon as its position has been revealed by the first defensive launch. Other countermeasures are discussed in Section 5.

3.4 SPACE-BASED PARTICLE BEAMS

Beams of atomic particles would deposit their energy within the first few centimeters of the target rather than at the very surface as with lasers. The effects of irradiation with the particle beam could be rather complex and subtle and would probably depend on design details of the attacking Soviet booster. The result is uncertainty of several factors of ten in the effective hardness of an ICBM booster to beam weapon irradiation.

Only charged particles can be accelerated to form high-energy beams, but a charged beam would bend uncontrollably in the Earth's magnetic field. (There is one theoretical exception to this statement, described below.) For this reason neutral particle beams, consisting of atomic hydrogen (one electron bound to one proton), deuterium (one electron, one proton, one neutron), tritium (electron, proton, two neutrons) or other neutral atoms are considered. To produce a neutral hydrogen (H°) beam, negative hydrogen atoms ($H-$) with an extra electron are accelerated; the extra electron is removed as the beam emerges from the accelerator.

Two features of neutral particles beams dominate their promise as boost phase intercept weapons (leaving aside entirely the issue of countermeasures). The first is the uncertain lethality of the beam. The second is the fact that the beam

cannot propagate stably through even the thinnest atmosphere and must wait for an attacking booster to reach very high altitude.

Generating Neutral Particle Beams

The accelerator that accelerates the negative hydrogen ion is characterized by its current in amperes, measuring the number of hydrogen ions per second emerging from the accelerator; and by the energy of each accelerated ion in electron volts (eV; 1 eV = 1 watt per ampere). Multiplying the current by the energy gives the power of the beam, so that a l-amp beam of 100 MeV particles carries 100 MW of power. Ground-based high-current accelerators and ground-based high-energy accelerators have been built and are operated daily in laboratories. One of the challenges for neutral particle beams as weapons is that they require *both* high current *and* high energy. Another challenge is to provide multi-megawatt power sources and accelerators in a size and weight suitable for space basing.

Magnets focus and steer the beam as it emerges from the accelerator. The last step is to neutralize the beam by passing it through a thin gas where the extra electron is stripped off in glancing collisions with the gas molecules, forming H° from H^{-}. The divergence angle of the beam is determined by three factors. First, the acceleration process can give the ions a slight transverse motion as well as propelling them forward. Second, the focusing magnets bend low-energy ions more than high-energy ions, so slight differences in energy among the accelerated ions lead to divergence (unless compensated by more complicated bending systems). Third, the glancing collisions that strip off the extra electron give the H atom a sideways motion. This last source of divergence is unavoidable and, by the Heisenberg uncertainty principle, cannot be controlled or compensated. It sets a lower limit on the divergence angle achievable with this method of producing neutral particle beams. Table 3.2 shows the divergence angle resulting from this third source, assuming perfect control of the first two sources. The divergence cone from a neutral particle beam is therefore about 10 times larger than the beam from the chemical laser of section 3.1 and 10 times smaller than from the x-ray laser of section 3.3.

A 100 MeV, 0.5 amp neutral tritium (T°) beam thus directs 50 MW of power into a cone of divergence angle 2 microradians, producing a spot 10 meters across at 5 Mm range. A target within this spot receives only 65 watts/cm², requiring 1.5 seconds of dwell time to deposit only 100 J/cm².

Booster Vulnerability to Particle Beams

As soon as the neutral particle beam hits the target, the remaining electron is stripped off, leaving the energetic proton (or deuteron or triton) penetrating deeply into the target. The proton scatters electrons in its path, giving up a small amount of its energy to the electron in each collision. When it has given up all its energy, it stops. For most of its path, it deposits energy uniformly. Thus if a 100 MeV T° beam penetrates 4 cm into the propellant in a missile, it deposits about 25 MeV along each cm. Protons penetrate more deeply than tritons of the same energy, and all particles penetrate more deeply as they are given more energy (table 3.3).

Table 3.2.—Neutral Particle Beam Divergence Angle

	H°	T°
100 MeV	3.6 microradians	2.0
500 MeV	1.4	1.0

Divergence angle introduced by stripping electrons from a beam of negative hydrogen or tritium ions to produce a neutral beam. This source of divergence is an unavoidable consequence of the Heisenberg uncertainty principle applied to the sudden stripping of the electron. If the satellite-based accelerator of the negative ions were absolutely perfect, this amount of divergence would remain.

Figure 3.10

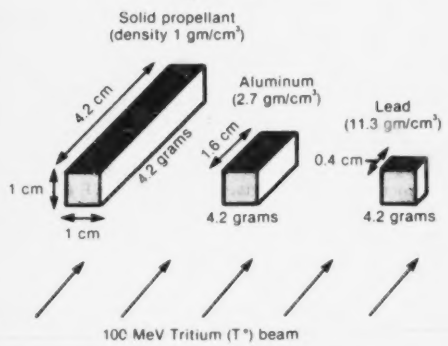

Figure 3.10 A neutral particle beam penetrates farther into an aluminum target than into a lead target but deposits the same energy per gram. Though the energy per gram needed to melt aluminum is well known, the utility of particle beam BMD concepts rests on the less certain destructive effects at lower levels of irradiation. Source: Author

Table 3.4.—Effects of Particle Beam Irradiation

Harmful effect	Energy deposition (Joules per gram)
Disruption of electronics	0.01—1.0
Destruction of electronics	10
Detonation of propellants, high explosive	200
Softening of uranium and plutonium	hundreds
Melting of aluminum	1,000

Approximate energy deposition (radiation dose) required to produce various harmful effects in components of a missile booster and its payload. Many other effects, such as melting of glue and plastic and rate-dependent effects, might also be important.

SOURCE: Author

The target electrons that recoil from collisions with beam particles eventualy stop, and their energy appears as heat. The 100 MeV T° beam described above, depositing 100 J/cm² on an aluminum target, penetrates to a depth of 1.6 cm. The 1.6 cubic centimeter volume of aluminum that absorbs this 100 joules of energy weighs about 4 grams. The effect of the beam is therefore to deposit about 25 joules per gram throughout the first 1.6 cm of the target. The penetration depth is inversely proportional to the density of the absorbing material, so the same beam on a lead target would not penetrate as far but would deposit the same energy *per gram* as it did in aluminum (fig. 3.10).

The destructive effects of penetrating particle beams are therefore expressed in joules/gram deposited within the target rather than in joules/cm² on the surface of the target as with lasers. Table 3.4 shows the energy deposition needed to produce certain harmful effects. Melting the target is straightforward, but for the other effects at lower levels of irradiation the criteria are less clear. Heat effects in solid booster propellants and in the high explosive and special nuclear materials in warheads depend on the design of the target. Effects on electronics, particularly transient disruption of computer circuits when electrons are scattered by a passing proton, are poorly known and doubtless quite complicated and specific to the target. Other components not shown in table 3.4 —plastics, glue, guidance sensors— make for a very complicated analysis. What is more, the particle beam might have to suffer the attenuation of passage through, say, two layers of aluminum and a layer of plastic before reaching a sensitive component.

Uncertainties in the destructive or disruptive effects of small amounts of radiation from a particle beam weapon is the principal obstacle to stating what energy, current, and divergence angle would make this concept a candidate for boost-phase intercept.

Shielding to protect components from a neutral particle beam would necessarily be heavy but could still be an attractive countermeasure. It is discussed in Section 5.

An Orbiting Neutral Particle Beam System

A critical limitation of neutral particle beams is that they cannot be aimed through even the thinnest atmosphere—air so thin that even the x-ray laser beam could pass through easily. A neutral beam could not attack a Soviet booster until the booster reached at least 160 km altitude (versus about 80 km for the x-ray laser)[7]. Collisions

[7]The stripping cross section on oxygen is about 1.5 megabarns. Elastic scattering can also be important for beam loss, since the RMS scattering angle can be larger than the beam divergence. The author is indebted to Dr. George Guillespe of Physical Dynamics, Inc., in La Jolla for results of his Born approximation cross section calculations.

between air molecules and H^+ strip the electron from the H^0, and gradually all the remaining protons spiral off the beam axis into 200 km wide circles under the action of the earth's magnetic field.

An MX-like Soviet booster could be attacked between 160 km altitude and burnout at 200 km, a period of about 10 seconds. This short attack window means that the neutral beam cannot afford to dwell for long on each booster.

It is impossible to state with confidence the resilience of an ICBM booster to irradiation with a neutral particle beam. But it is likely that faith would have to be placed in degradation of electronics and other subtle effects, rather than in gross structural damage, for the beam weapon to stand a chance as an economical defense system (ignoring the issue of countermeasures entirely).

Consider again a battle station producing a 0.5 ampere beam of 100 MeV tritium (T^0) atoms with 2 microradian divergence. This beam carries 400 watts/cm² at 2 megameters range. To do structural damage to the outer few centimeters of a missile's body might take some 2 kJ/cm² (depositing 500 J/gm in 1.6 cm depth of aluminum, for instance), requiring 5 seconds of dwell time at this range. Since the available dwell time is only about 10 seconds, each beam could handle only two boosters. With a constellation size of almost 100 for 2 Mm range (fig. 3.4), this kill criterion results in a preposterous system where the U.S. deploys 50 space-based accelerators for every one Soviet booster deployed in one region of the U.S.S.R.

If the assumed Soviet booster hardness is reduced by 100 times, corresponding perhaps to transient upset of unshielded electronics, each satellite can destroy 200 boosters at 2 Mm range, meaning an overall tradeoff of one U.S. accelerator deployed for each two Soviet boosters deployed. Alternatively, the constellation can be thinned out to an effective range of 5 Mm, where each satellite at this range can destroy only 32 boosters but the constellation size is only about 16—still a one-to-two trade of battle stations for Soviet boosters. Such a system scarcely seems promising in terms of cost exchange.

Obviously the neutral particle beam would stand no chance of intercepting a fast-burn booster that burns out well within the protective atmosphere. Even an MX-like booster that flew a slightly depressed trajectory would be invulnerable.

A Theoretical Electron Beam System

Physical theory[8] holds out the prospect of one other type of beam besides the neutral particle beam. Under certain circumstances, an electron beam might be able to propagate through the extremely thin air of near-earth space without bending. In this scheme, a laser beam would first remove electrons from air molecules in a thin channel stretching from the battle station to the target, leaving a tube of free electrons and positive ions. The high-energy, high-current electron beam would then be injected into the channel. The beam electrons would quickly repel the free electrons from the channel, leaving the beam propagating down a positively charged tube. The attractive positive charge would prevent the electrons from bending off the beam path under the influence of the geomagnetic field and would also prevent the mutual repulsion of electrons within the beam from causing the beam to diverge. The result would be straight-line propagation to the target, where their effect would be similar in most respects to the neutral particle beam. This scheme will not work for a proton beam.

The physics of intense beam propagation through thin gases is so complex that experiments will be needed to determine whether this concept is even feasible in principle. If so, the concept would resemble the neutral particle beam, with the added requirement for the channel-boring laser and perhaps the ability to intercept boosters at slightly lower altitudes than the neutral counterpart.

[8] R. B. Miller, *The Physics of Intense Charged Particle Beams*, New York, 1982, ch. 5.

3.5 SPACE-BASED KINETIC ENERGY WEAPONS

Kinetic energy is the name given to the energy of a moving projectile. Use of this term makes ordinary weapons using aimed projectiles into "directed kinetic energy" weapons.

The phenomenology of high-velocity collisions between a projectile and a structure like a booster is surprisingly complex, but in general lethality is not an issue for kinetic energy boost phase intercept concepts. Rather, the problem is getting the projectile from its satelliite base to the ascending booster in time to make an intercept. Schemes where the projectile is carried by a small rocket launched from the satellite suffer most directly (leaving aside countermeasures) from a combination of the large number and large size of the rockets needed for adequate coverage. In particular, the most conspicuous public example of the kinetic energy approach, the High Frontier Project's Global Ballistic Missile Defense (GBMD) concept,[9] has extremely limited capability for boost phase intercept of current Soviet ICBMs and would have no capability at all against a future generation of MX-like boosters.

Kinetic Energy Concepts

Rocket attack of ICBM boosters is obviously not as novel as beam attack, but it entails rather more complexity than appears at first blush. The rocket needs radio or other guidance by long-range sensors on its carrier satellite (or other satellites) to direct it to the vicinity of its target, since it is impractical to put a long-range sensor on each rocket. Once in the vicinity of the target booster, the interceptor needs some form of terminal homing sensor and rather sizeable divert rocket motors. Homing on the plume of the ICBM booster is not straightforward, since attacking the plume will obviously not harm the booster: the booster body must be located in relation to the plume. These complications introduce opportunities for offensive countermeasures.

An alternative to rocket propulsion would be to expel the homing vehicles at high velocity from a gun. So-called rail guns use a clever scheme to convert electrical energy to projectile kinetic energy. Since a 10 kilogram projectile ejected with 5 km/sec velocity carries 125 megajoules of energy (the amount of energy expended by a 25 megawatt chemical laser in 5 seconds of dwell on a booster), the power requirements of the gun schemes are imposing. Providing chemical fuel or explosives to power a gun therefore involves the same magnitude of on-orbit weight as the chemical laser.

Doing away with the homing sensor and replacing the guided projectile with many small fragments is not an attractive alternative, since the needed fragments end up weighing far more than the guided projectile.

The Importance of Projectile Velocity

In the 300 or so seconds from launch to burnout of a slow-burning booster like the SS-18, the defensive rocket or other projectile must fly from its satellite to the path of the booster. Such a booster burns out at about 400 km altitude, so if the projectile wishes to use the entire 300 seconds of boost phase to travel to its quarry, it must make its intercept at 400 km altitude.

Suppose now that the projectile's rocket or gun launcher can give it a maximum velocity of 5 km/sec with respect to the carrier satellite. In the 300 seconds of available travel time to its target, the projectile cannot fly more than (5 km/sec) × (300 sec) = 1.5 Mm from its carrier. Each carrier therefore has an effective range of 1.5 Mm (fig. 3.11a).

Referring to figure 3.4, a constellation of about 240 carrier satellites are needed for continuous coverage of the Soviet Union. Since Soviet ICBMs are spread over much of the country, 10 or so of the carrier satellites might be able to participate in a defensive engagement. The absentee ratio is therefore about 24. The 10 satellites over the U.S.S.R. at the moment of a massive Soviet attack need to be able to handle all 1,400 boosters, meaning each satellite needs to carry 140 projectiles.

An idealized rocket accelerating a 15 kg guided projectile to 5 km/sec velocity would need to weigh about 80 kg (a real rocket with this capa-

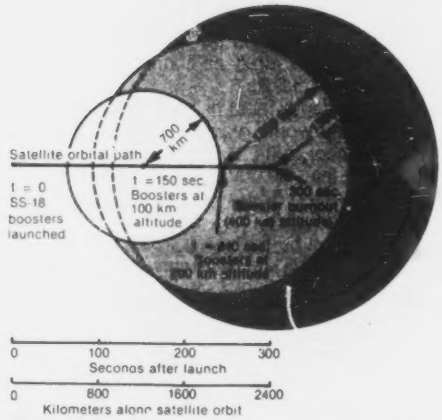

Figure 3.11(b)

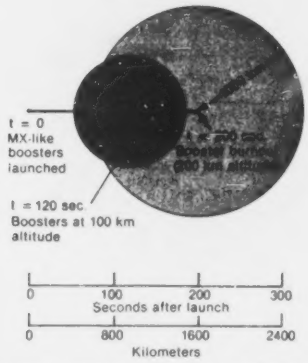

(b) Same as (a), except the target is the faster-burning MX.

Figure 3.11 View from above (looking down on earth) of coverage by a satellite carrying kinetic energy boost-phase intercept vehicles. The satellite is deployed in a 400 km orbit. At time t=0, offensive boosters are launched. The satellite can make intercepts by shooting downward or wait until the boosters rise to their burnout altitude and fire nearer to the horizontal. The longer after launch the intercept is made, the farther the rocket intercept vehicles can travel from the satellite to make the intercept. Smaller circles thus correspond to downward firing, larger circles to horizontal firing. The satellite moves from left to right in accordance with its 8 km/sec orbital velocity. The area enclosed by all the circles taken together gives the total coverage of the satellite and determines how many satellites are needed in the worldwide constellation for continuous coverage of opposing ICBM fields. All dimensions are to same scale.
(a) The satellite-based kinetic energy interceptors are capable of 5 km/sec velocity relative to the satellite. The attack is on a slow-burning Soviet SS-18.

bility would weigh more like 200 kg). Each carrier satellite must therefore weigh (140) × (80) = 11,000 kg. Less than twice this weight can be carried by the space shuttle into the appropriate orbits, so establishing the total 240 satellite constellation requires over 120 shuttle launches in this highly idealized model with idealized rockets and weightless carrier satellites. (A more careful estimation of interceptor design would more than double this load.)

From this baseline, we can consider five excursions:

1. Suppose the velocity capability of the interceptor is doubled to 10 km/sec, doubling the effective flyout range to 3 Mm. At this range, 48 satellites complete the constellation, with perhaps as many as eight of them in position to participate in the engagement. Each of the eight satellites must handle 175 Soviet boosters.

   Doubling the velocity capability more than doubles the weight of the rocket required. The reason is simple: to increase the velocity requires more propellant, and the extra propellant must itself be accelerated, requiring yet more propellant. The rocket weight thus grows exponentially with velocity capability. The idealized 10 km/sec rocket weighs 420 kg. Each satellite carrying 175 rockets then weighs 75,000 kg and requires some five shuttle launches to orbit. The result is that over 200 shuttle launches are required to orbit the entire (idealized) defense system. Increasing the velocity capability is therefore no escape from large on-orbit weights.
2. The current Soviet ICBM force consists largely of slow-burning liquid-fueled boosters distributed widely over the Soviet Union. Consider the consequences for the U.S. kinetic energy defense system if the Soviets de-

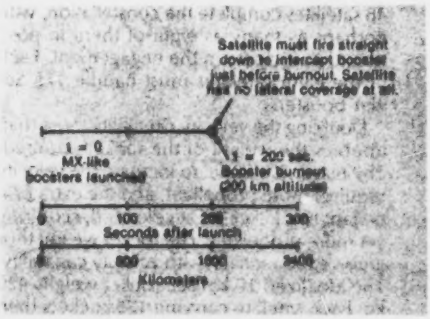
(c) The High Frontier Global Ballistic Missile Defense (GBMD) concept, with intercept vehicles capable of only 1 km/sec velocity relative to the satellite. Intercept of SS-18. In the actual High Frontier proposal, the satellites are in 600 km orbits, giving them even less coverage than shown here.

Figure 3.11(d)



(d) The High Frontier concept has no capability whatsoever for boost-phase intercept of MX.

ploy 100 faster-burning MX-like boosters in one region of the country, so that defensive interceptors have less time to fly to their targets and only one satellite overhead participates in the engagement. MX burns out 200 seconds after launch, so each satellite has an effective range of 1 Mm, requiring a constellation of 400 satellites (fig. 3.11b). Each satellite must carry the 100 80-kg rockets needed to handle the attack. An exchange ratio of four 8,000 kg U.S. defensive satellites for every Soviet offensive booster deployed is surely an economic advantage for the U.S.S.R.

3. Soviet deployment of 1,000 Midgetman-like boosters would require a compensating deployment of 400 U.S. satellites, each weighing at least 80,000 kg. A system that forces the United States to such a response is clearly absurd.
4. Soviet fast-burn boosters would be totally immune to the kinetic energy defense system. An interceptor on a satellite in 400 km orbit (lower orbits shorten satellite lifetimes because of atmospheric drag) could not even descend straight down to the fast-burn booster's 100 km burnout altitude in the required 50 seconds, much less have any lateral radius of action.
5. Intercepting SS-18 or MX post-boost vehicles is clearly easier, from the point of view of flyout velocities, than boost-phase intercept. Satellites at 700 km or so altitude would have 500 seconds to fly out to meet the bus when it ascended to their altitude, giving a 2.5 Mm lethal radius.

In conclusion, a rocket-propelled kinetic energy system acting against today's Soviet ICBM arsenal (with no Soviet countermeasures) would require many heavy satellites and would be a dubious investment for the U.S. Soviet deployment of MX-like or Midgetman-like boosters would nullify the United States defense or force the U.S. to large investments in new satellites.

Analysis of the High Frontier Concept

The High Frontier Program[10] proposes a Global Ballistic Missile Defense (GBMD) using rocket propelled interceptors for boost phase intercept. This concept claims to have some utility, at least against the present Soviet ICBM arsenal.

The concept consists of 432 satellites (24 planes of 18 satellites in circular orbits inclined 65 degrees) at an altitude of 600 km. A velocity

[10]Ibid.

capability of 1 km/sec relative to the satellite ("truck") is attributed to the interceptor. The interceptors are apparently command guided to the vicinity of the target. The homing sensor is not specified, but short wave infrared homing on the hot rocket plume is implied.

Consider this concept defending against the SS-18 in its boost phase. Since the SS-18 burns out at 400 km altitude 300 seconds after launch, each GBMD satellite has a 0.3 Mm radius of action. Since the satellites are deployed at 600 km altitude, the interceptor must descend 200 km to make an intercept just before burnout, resulting in a lateral radius of action of 0.22 Mm (compare fig. 3.11c, where the satellites are assumed deployed at 400 km altitude). With a range this small, thousands of satellites would be needed worldwide for continuous coverage of Soviet ICBM fields. The High Frontier concept with only 432 satellites would therefore have meager coverage of Soviet ICBM fields.

The GBMD concept would have no capability whatsoever against an MX-like booster. Such a booster would burn out before the interceptor could reach it, even if the interceptor were fired straight down (fig. 3.11d).

It is possible that the High Frontier concept is designed for post-boost intercept rather than boost phase intercept. Its coverage for post-boost intercept, though greater than for boost-phase intercept, would still be only partial. The only example given in the description[11] of the system is of *boost phase* intercept of an SS-18, however. In this example the interceptor is launched 53 seconds *before* launch of its target booster, though no explanation is given of how the U.S. defense knows *in advance* the precise moment at which the Soviets would launch a given booster. This early launch allows the interceptor to reach its target seconds before burnout. Plume homing, a technique inappropriate for bus intercept, is also implied for the High Frontier concept. Post-boost intercept permits some RVs to be deployed on trajectories carrying them to the United States before intercept; and the entire bus, with its warheads, would continue on to the U.S. after the interceptor collision, with uncertain consequences.

It would therefore appear that the technical characteristics of the High Frontier scheme result in a defensive system of extremely limited capability for boost phase intercept of present Soviet ICBMs and no capability against future MX-like Soviet boosters, even with no Soviet effort to overcome the defense.

[11] Ibid., p. 103.

3.6 MICROWAVE GENERATORS

Microwaves are short-wavelength radio waves used in radar, satellite communications, and terrestrial communications relays. A number of ideas have been conceived for generating microwaves in space and directing them towards ascending ICBM boosters. The principal technical problem with this type of BMD, generator technology aside, is the uncertain effect the microwaves would have on their target.

The microwaves would propagate through the atmosphere unattenuated at all but the highest power levels. The weapon divergence angle would be very large, producing a spot many km wide at a few hundred km range. From these considerations the following concept emerges: As Soviet ICBMs lift off from their silos, a few microwave generators in space bathe the silo fields with microwaves.

At high power levels, as in a microwave oven, microwaves cause heating in many materials. But in the BMD scheme, the divergence cone is so large that even a prodigious amount of energy emitted from the generator would lead to very small energy deposition per square centimeter on the target (millions of times less than lasers). The microwave pulse received at the booster

would resemble the high frequency component of the electromagnetic pulse (EMP) from a high-altitude nuclear detonation. However, even weak microwaves can upset sensitive circuitry if they can reach it.

A metal skin on the booster would stop the microwave pulse altogether from reaching internal electronics. The microwave defense must therefore hope that some aperture or conduit is available into the booster, whether by design (as in an antenna), inadvertence, or poor maintenance. If so, and if the electronic circuitry is not or cannot be made resistant to disruption or burnout, the part of the booster's performance dependent on those electronics (perhaps accurate guidance) would be affected.

Because of the very uncertain lethality of microwaves, deployment of space-based generators (if they can ever be built) would be a harassing tactic rather than a confident-kill ballistic missile defense.

3.7 OTHER CONCEPTS

Other directed energy concepts suitable in theory for ballistic missile defense have been broached from time to time. Some of them are listed below. It is quite possible that in a few years time a revisit to this subject will find a new panoply of concepts enjoying the front rank of discussion.

1. **Short-wavelength chemical lasers** would combine the simplicity and efficiency of the HF chemical laser with the small mirrors of the short-wavelength excimer and free-electron lasers. Though some ideas have been advanced along these lines, no laser exists which can be said to be a candidate to fulfill this theoretical promise.
2. **Explosive-pumped lasers and particle beams** are said to be under study in the Soviet Union.[12] Such devices might possibly be quite compact, each bomb generating a single huge pulse for impulse kill of a booster. All these schemes are at a very early conceptual stage.
3. **Antimatter beams** would penetrate into a target just like ordinary particle beams, except that when the antiparticle reached the end of its range it would annihilate a particle in the target, freeing a large extra amount of harmful energy. Acceleration of antimatter beams is accomplished exactly as with particle beams, and laboratory beams of antimatter have been used routinely in pure research. One important difference is that antimatter is not freely available in the universe as is matter; the antimatter for the accelerator would have to be produced by the defense system, a formidable and complex undertaking. It is not clear that the extra energy released in the target by an antimatter beam would justify the trouble of producing the beam.

Section 4

OTHER ESSENTIAL ELEMENTS OF A BOOST-PHASE INTERCEPT SYSTEM

The previous section treated only the defensive weapon itself, the so-called "kill mechanism." But if beam weapons ever evolve to the point where deployment is a serious possibility, other elements of the overall defensive system will emerge as equally important determinants of cost and level of protection. After all, the interceptor missile in traditional BMDs has not been the central focus of attention or technical debate since the 1950's, when it became clear that a "bullet could hit a bullet." Discussion of BMD at that point passed to the difficult issues of radar performance, data processing capability, and vulnerable basing of defensive components—issues that had nothing to do with the kill mechanism. In a similar manner, the other essential elements of a boost-phase intercept system will figure more prominently in discussion of boost-phase BMD if and when the kill mechanisms—lasers, mirrors, accelerators—are in hand. These other essential elements introduce their own technological problems and opportunities for offensive countermeasures. If traditional BMDs are any guide, provision of a kill mechanism will be just the beginning of making an efficient, robust defensive system.

4.1 TARGET SENSING

Locating and tracking an ICBM booster with enough precision to aim a directed-energy weapon is not as straightforward as is sometimes supposed. It is true that booster motors emit hundreds of kilowatts of power at short- and medium-wave infrared (SWIR and MWIR) wavelengths of a few microns. Sensors can detect these plumes at great distances from the earth. Plume sensing is used today for early warning of missile attack to support launch of bombers and airborne command posts and launch under attack of ICBMs.

To be useful for directed-energy BMD, however, the sensor must localize the booster within an area as small as the beam spot. Otherwise the beam would have to sweep wastefully back and forth over the area of uncertainty. Small divergence beams must therefore be accompanied by sensors with small angular resolution.

Diffraction limits the angular resolution of a sensor in the same way it limits the divergence angle of a laser. A large infrared telescope with 5 m diameter mirror observing MWIR booster emission at 4 micron wavelength would have angular resolution no more precise than a microradian. Such a sensor affixed to each battle station in a defensive constellation would localize ascending boosters to within a spot 5 m wide at 5 Mm range. At this range, the (illustrative) systems described in Section 3 have spot sizes: 1.5 m for the HF laser, 0.6 m for the ground based laser, 10 m for the neutral particle beam, and 100 m for the x-ray laser. Even a large infrared sensor on each battle station would therefore be inadequate for directing the laser beams at a point source of MWIR light, marginal for directing the neutral particle beam, and adequate for directing the x-ray laser. The actual situation would be worse still, since the booster is not a point source. The booster plume would be larger than the laser or particle beam spots, and the booster body would need to be located in relation to the plume to avoid wasting beam time attacking the plume.

For directed-energy weapons with small divergence angles, therefore, sensing the conspicuous rocket plume is inadequate. Another kind of sensor must be introduced into the BMD system. For finer angular resolution one looks to shorter wavelengths, in the visible or ultraviolet. At these wavelengths the sensor must provide its own illumination. A so-called laser radar or ladar is the only practical solution. In a ladar, a low-power

visible or ultraviolet laser shines on the booster body, and a telescope on board the battle station senses the reflected light.

Besides the annoyance of a new laser and new sensor, the necessary introduction of ladar into the boost-phase system creates opportunities for the defense to spoof and blind the offensive sensor.

Kinetic energy systems do not need precision long-range sensing, since the rocket or guided projectile homes on the target when it comes within short range. The terminal homing might involve deducing the location of the booster body in relation to its MWIR plume, homing on low-power laser light shined from a defensive satellite and reflected from the target, or some other method. These homing methods are susceptible to countermeasures.

Though this Background Paper treats only intercept of the booster proper, it is worthwhile pausing to consider tracking of the post boost vehicle or bus. The low thrust levels of the post boost vehicles's rocket motors, their intermittent operation, the possibility of dimming them with propellant additives, and the possibility of building decoys with small rocket motors all suggest that MWIR plume sensing is not practical for post boost intercept. The alternatives are ladar or radar, suggesting again many opportunities for countermeasures.

4.2 AIMING AND POINTING

The directed-energy beam must be aimed and stabilized as accurately as it is collimated. If the beam waves around too much, the effective divergence increases, and the beam wastes energy missing the target. The mirrors or other mechanism steering the beam must be stabilized despite vibrations in the battle station caused by the beam's large power source.

In the 15 milliseconds the beam takes to travel from the battle station to a booster 5 Mm away, the booster moves about 50 m. A narrow beam must therefore lead the target. In one second of dwell time, the target moves several km; the beam must remain on the target, sweeping through the sky at the necessary angular rate while still maintaining its aim and jitter control.

4.3 INTERCEPT CONFIRMATION

A desirable, though perhaps not essential, function of BMD systems is confirmation that an attempted intercept succeeded. This function is sometimes called "kill assessment." Intercept confirmation would allow the beam to move onto subsequent boosters with more than a statistical estimate that its previous task was accomplished. Structural damage to the booster would presumably be revealed by an erratic course or burn pattern, though it might be difficult to say in advance exactly what the sensor's view of the wounded booster would be. Subtle damage inflicted by a particle beam or microwave generator might not be visible. Damage to a bus would be difficult to assess and interpret if the debris, including RVs (perhaps arranged by the offense to separate from the bus under extreme circumstances), continue on their ballistic course to the continental United States.

Related to intercept confirmation, and ultimately more serious, is the question of determining whether the beam is missing the target (perhaps by slight misalignment of sensor and beam boresights, miscalibration of aiming mechanisms, etc.) and, if so, by how much and in what direction. It might be possible to observe a glowing column of air where a laser beam passes through the at-

mosphere. Some clever but elaborate schemes have been devised to track a neutral particle beam. Obviously each new complication added to the defensive system potentially creates new opportunities for offensive countermeasures.

4.4 COMMAND AND CONTROL

The crucial infrastructure of command and control of a complex system is always the last to take shape, since it integrates the workings of all the separate components. It is easy to ignore the difficulty of accomplishing this last step at this early stage when the other components of a boost phase system are not yet remotely in hand. The command and control system of a boost-phase intercept system would comprise communications links among its far-flung components, data processing to support sensors and battle station operations, and "battle management" software incorporating all the instructions and decisions needed to run the defensive engagement and to coordinate the defense with U.S. offensive forces.

Communications and data processing are two areas of technology where there is the least pessimism—looking two or so decades into the future when boost-phase systems could presumably be deployed—that technology will be able to meet the needs of directed-energy defenses. Compact, lightweight, and rapid data processing hardware is virtually assured, though interesting questions attend on hardening, reliability, and lifetime in space. Software would be expensive and would introduce issues of reliability and security from programmer sabotage. Satellite-to-satellite communication via extremely high frequency radio and laser offers high data rates and virtual immunity to jamming from earth or from space.

Command and control for BMD does introduce two interesting issues to which technology cannot provide an answer. The first is the impossibility of testing the whole defense system from end to end in a realistic wartime setting. Unlike the air defense systems of World War II, which learned through attack after attack to exact kill rates of several percent, the BMD system would have to work near perfectly the very first time it was used. The second issue is the likely need for the defense to activate itself autonomously, since there would be no more than a minute for human decision.

4.5 SELF-DEFENSE

Consideration of anti-satellite (ASAT) attack (see Section 5.1), and analogy with traditional BMD systems (where vulnerability of key radars, data processors, and other components is usually the chief limitation on defense performance) suggest that self-defense mechanisms could well end up being a large part of the defense system. These mechanisms could include shields, escort weapons, and countermeasures to ASAT sensors. Unless and until a credible overall approach to satellite survivability is found, one cannot specify the needed hardware.

Ground-based BMD lasers and pop-up x-ray lasers would obviously need to be protected from precursor attack by cruise missiles and other delivery systems.

4.6 POWER SOURCES

Chemical lasers, x-ray lasers, and rocket-propelled kinetic-energy interceptors have power sources integral to the weapon, but excimer lasers, free electron lasers, neutral particle beams, and rail guns would need sources of electrical power and the equally important means to convert electricity into a form usable by the weapon ("power conditioning"). Space basing obviously complicates the task. Large commercial power plants on the ground produce about 1,000 MW of power, and directed energy weapons might require hundreds of MW. On the other hand, the power plants on defensive satellites need not work reliably for many years but only once for a short time, and they need not be very highly efficient. The three alternatives for space power are fuel burning, explosives, and nuclear power. Starting up a large power source in seconds from a condition of dormancy poses some interesting design issues.

Section 5

COUNTERMEASURES TO BOOST-PHASE INTERCEPT

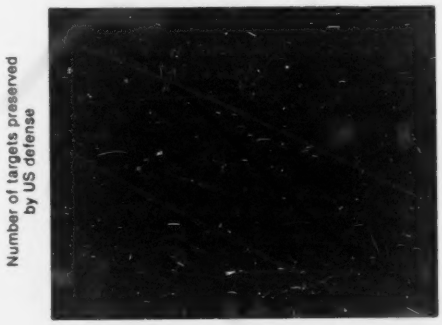
Countermeasures that limit the effectiveness of traditional ballistic missile defenses—decoys, radar blackout, defense suppression, etc.—are well known. A comparable set of countermeasures, no less daunting for being less familiar, faces the designer of boost-phase defenses.

The need to resort to countermeasures imposes a cost on the offense. This cost is measured in money to build more or specialized offensive hardware, but also in the time needed to do so, in constraints upon the type of attack the offense can incorporate in its nuclear planning, and in the confidence with which it can predict a "successful" outcome of the strike.

Every BMD system actually proposed for deployment would be accompanied, at least ideally, by, first, an analysis of its degradation in the face of an improving Soviet offense and, second, by an analysis of how much it would cost for the United States to improve its defense in such a way as to avoid being overcome.[1]

[1]See *Ballistic Missile Defense*, ed. Ashton B. Carter and David N. Schwartz (The Brookings Institution, 1984), ch. 4.

Figure 5.1



Number of targets preserved by US defense
Soviet investment in offense
(more ICBMs, new types, special countermeasures, etc.)

Fig. 5.1. Schematic drawdown curve, showing how the performance of a BMD system degrades as the size and sophistication of the attacking force increase.

Figure 5.2

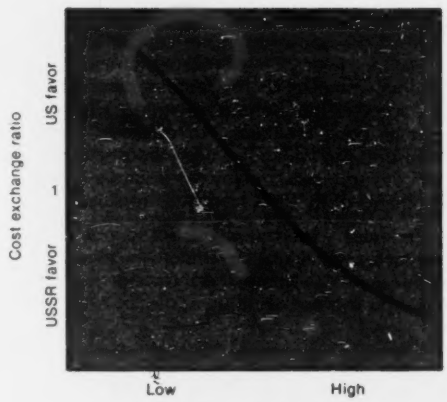


Fig. 5.2. The marginal cost exchange ratio measures the outcome of a race between the Soviet offense to enhance its penetration and a U.S. defense to maintain its level of protection. In general, modest defense goals (e.g., "preserve 40 percent of the targets") are easier to sustain than high goals ("preserve 95 percent of the targets") against improvements in Soviet offensive forces, including deployment of countermeasures.

The first analysis would be expressed in a drawdown curve such as that shown in figure 5.1. The Soviets can overcome the defense and destroy a large number of U.S. targets, but to do so the Soviets must "pay" an "attack price."

The second analysis would be encapsulated in the cost exchange ratio. The marginal cost exchange might be defined as follows: "Assume that in the year 2000 the U.S. defense and Soviet offense have evolved so that each has a certain level of effectiveness. Suppose the Soviets wish to improve their position and the U.S. resolves to maintain the status quo. Which side spends more in the competition?" For example, suppose every time the Soviets add 100 ICBMs to their arsenal, the United States has to add 20 satellites to its defensive constellation to intercept them: Which costs more, 100 ICBMs or 20 satellites?

In general, high levels of defense performance are harder to enforce in the face of offensive improvements than low levels: this important fact is shown schematically in figure 5.2 (see also Section 8.2).

All of the boost-phase intercept schemes discussed in this report are in such an early stage of conceptualization that nothing remotely like the analyses represented by Figures 5.1 and 5.2 can be done for them. Nonetheless, countermeasures are known for every boost-phase system devised, and in many cases simple heuristic estimates of the cost tradeoffs are suggestive.

Technical experts disagree not so much about the facts and calculations underlying these countermeasures as about the interpretation to be given to them. Should an apparently fatal flaw uncovered at this early stage of study of a defensive concept be decisive, or should work (and the inevitable expectations that accompany it) continue on the chance that a new idea will turn up to rescue the concept? Would the Soviets really resort to a subtle tactic or exotic piece of hardware as a confident basis for their nuclear policy? Some analysts see BMD as a way of "forcing" the Soviets to take a certain direction in their pursuit of the arms race, e.g., away from large, slow-burning MIRVd boosters to single-warhead Midgetman-like boosters. In this view, defeat of the BMD is purchased at the price of a theoretically more stable and desirable Soviet offensive posture. All these questions of judgment loom large in making a final assessment of a given countermeasure.

5.1 ANTI-SATELLITE (ASAT) ATTACK, INCLUDING DIRECTED-ENERGY OFFENSE

All boost-phase intercept BMD concepts have crucial components based in space. Even a pop-up defense would need warning and very probably target acquisition sensors on satellites over the Soviet Union. Ground-based laser defenses would have mirrors and sensors—their most fragile components—in space. Vulnerability of these satellites is a cardinal concern because their orbits are completely predictable (they are in effect fixed targets), they are impractical to harden, conceal, or proliferate to any significant degree, and because successful development of effective directed-energy BMD weapons virtually presupposes development of potent anti-satellite (ASAT) weapons. ASAT is the clear boost-phase analogue of familiar defense suppression tactics against traditional BMDs, where attack is first made upon the defensive deployment (especially fixed radars) and then upon the defended targets.

The interplay of ASAT techniques—missiles (nuclear or conventional), space mines, directed energy—and satellite defense (DSAT) techniques is a complex one. It is difficult to generalize, but in the specific case of large battle stations in low-earth orbit it would seem that the advantage is very likely to lie with ASAT, not DSAT. For one thing, the offense need not destroy a large number of defensive satellites, but only "cut a hole" in the defensive constellation. Second, the traditional military refuges all offer complications: concealment from radar, optical, infrared, and electronic detection, while possibly successful for small payloads in supersynchronous orbits, is impractical for large, complex spacecraft at most a few thousand km from the earth's surface; decoy satellites must generate heat, stationkeep, and give status reports, and they are in any event only useful if the ASAT designer is somehow restrained (perhaps by cost) from shooting at all suspicious objects; hardening imposes weight penalties, and massive shields could interfere with the constant surveillance and instant response required of the defense; proliferation is useless for expensive satellites facing inexpensive ASAT methods. As a consequence, discussions of DSAT for BMD battle stations usually emphasize large keep-out zones around the satellites and active self-defense. A third reason why ASAT is likely to prevail over DSAT is that possession by the offense of the same type of directed energy satellites used by the BMD probably assures successful first

strike. Fourth, the Soviets would pick the time and sequence of their attack, and it would occur over Soviet territory.

Two rather novel ASAT threats are worthy of note. The first is the x-ray laser itself. The x-ray laser, if it could be developed, would constitute a powerful space mine. Because of its long range, it could lurk thousands of km from its quarry. The Soviets might also launch x-ray lasers a few seconds before launch of their main attack. Recall that the well-known phenomenon of bleaching (see Section 3.3) would probably allow such x-ray lasers to shoot out of the atmosphere at a U.S. x-ray laser defense, but the U.S. x-ray lasers could not shoot down into the atmosphere at the ascending lasers.

A second ASAT tactic, discussed for many years, imagines the Soviet Union exploding nuclear weapons at high altitudes in peacetime with the intent of shortening the orbital lifetimes of the U.S. defensive satellites. The nuclear bursts inject further radiation into the van Allen belts that circle the earth's equator from about 1,500 to 10,000 km altitude. Satellites (more likely carrying sensors than weapons at these altitudes) passing through the belts accumulate a radiation dose that gradually degrades electronics, sensors, and optical surfaces. This possibility, if taken seriously, would require defensive satellites designed to withstand rather substantial accumulated radiation doses.

A detailed treatment of the ASAT problem is beyond the scope of this Background Paper. The following "parable" illustrates some of the problems encountered in trying to ensure the survivability of a defensive constellation, taking the 20 MW HF lasers of Section 3.1 as an example.

The United States deploys the HF lasers in this hypothetical system in low orbits at 1,000 km altitude. Higher altitude would place them too far from their targets. This is unfortunate: higher altitude (say, between 2,000 km and semisynchronous orbit at 20,000 km) would move the satellites further from ground-based ASAT weapons and put them into lesser-used orbits where staking out a sanctuary would involve less interference with foreign spacecraft.

Suppose the battle station designers have succeeded in the considerable task of making the satellites resilient to multi-megaton nuclear space mines (bombs, not x-ray lasers) as little as 100 km away. To keep all Soviet spacecraft (i.e., all potential mines) at least 100 km away, the United States claims for itself the orbital band between 900 and 1,100 km altitude. Perhaps the Soviets are awarded some other orbital zone for their own military purposes. The United States establishes the following rules in its zone: 1) No foreign spacecraft may transit the zone without prearrangement; 2) All transiting vehicles must remain at least 100 km from all U.S. battle stations, passing through a "hole" in the constellation; 3) Foreign spacecraft failing to obey these rules may be destroyed by the U.S. lasers.

Consider first a Soviet kinetic energy ASAT deployed at 1,100 km altitude, just outside the U.S. keepout zone. Suppose the rocket interceptors on the Soviet satellites have the same propulsive capacity—one km/sec—as the proposed High Frontier Global BMD system. The Soviet ASATs are then just 100 seconds away from the U.S. lasers. The U.S. lasers must therefore be very vigilant to avoid surprise attack. Fortunately, at 100 km range the 20 MW laser with 10 m mirror would burn up even a heavily hardened ASAT rocket in short order. Since starting up the main laser for self-defense might be awkward, wasteful of fuel, or time consuming, each U.S. battle station might be escorted by a satellite carrying a smaller laser or rockets for self-defense.

A constellation of Soviet 20 MW, 10 m HF lasers (the same technology as the U.S. lasers) at 1,100 km is another matter. These lasers could attack the U.S. lasers seconds before launch of a Soviet ICBM attack. The United States would have to keep these Soviet spacecraft *thousands* of km away from the U.S. constellation. That is, the United States would have to dominate near-earth space. Suppose the United States does so.

Now the Soviets build a fleet of pop-up x-ray lasers. These lasers climb to 100 km or so altitude, where information radioed to them from the ground allows them to point their rods at the U.S. lasers and detonate. The Soviets have had poor

success at building an x-ray laser; theirs are 100 times less bright than the ideal x-ray laser described in Section 3.3. Nonetheless, by pointing all its lasing rods at the same target, a Soviet x-ray laser can destroy a U.S. laser battle station at 10 Mm range. The U.S. chemical lasers attack the Soviet x-ray lasers as they ascend, but at this range long dwell times are required to destroy the Soviet lasers. By launching enough x-ray lasers simultaneously, the Soviets succeed in getting some to 100 km altitude, where they can shoot out through the thin atmosphere, before the U.S. lasers can destroy them. In this way, the Soviets "punch a hole" in the U.S. defensive constellation. (At a minimum, the Soviet ASAT attack consumes precious laser fuel aboard the U.S. battle stations.)

Just to make sure, the Soviets also deploy some powerful ground-based excimer or free electron lasers to destroy the U.S. battle stations as they orbit helplessly through space.

5.2 FAST-BURN BOOSTERS

Shortening the boost time and lowering the burnout altitude is easily accomplished at little sacrifice in useable ICBM payload (see Section 2). Shorter boost time increases the number of lasers needed for space-based laser or ground-based laser systems to handle simultaneously launched boosters. Short burn time makes rocket-propelled kinetic energy systems impractical, since the radius of action of each satellite becomes too small. Short burn time, together with low burnout altitude, would severely compromise the effectiveness of x-ray lasers popped up even from subs near Soviet shores. Low burnout altitude nullifies the neutral particle beam, which cannot penetrate very far into the atmosphere.

Fast-burn boosters would therefore be a potent, even decisive, countermeasure against almost all concepts for boost-phase intercept.

5.3 COUNTER C³I TACTICS

Countermeasures to the crucial functions of target sensing and command and control are a relatively unexplored, but probably key, problem area for directed energy BMD. In the case of terminal and midcourse defenses, the issues of decoy discrimination, confusion caused by chaff and aerosols, radar blackout and infrared redout, radar jamming, and traffic handling have always been and remain central limitations. It is likely that analogues will be found for boost-phase systems. Devising countermeasures requires a degree of specificity about the nature of the defense system which cannot be provided in the present conceptual stage. There follow a few examples of C³I countermeasures, by no means an exhaustive list.

A first point to note is that sensors are likely to be the most vulnerable part of a defensive satellite. A laser shined into an optical sensor can daze or injure the focal plane elements, though viewing in frequency bands absorbed by the atmosphere offers protection from ground-based lasers. Mirrors would be very susceptible to damage from a Soviet x-ray laser. A Soviet neutral particle beam could disrupt electronic circuits on U.S. satellites. Radiation pumped into the van Allen belts by nuclear bursts would affect sensors and electronics.

A single nuclear burst causes the upper atmosphere to glow brightly over areas 100 km in radius for over a minute. Calculated radiances[2] are large enough to cause background problems for MWIR tracking sensors.

[2] S. D. Drell and M. A. Ruderman, *Infrared Physics*, Vol. 1, p. 189 (1962).

Some directed-energy weapons produce spots only meters wide at the target, requiring target sensing to commensurate precision via laser radar (see Section 4.1). Laser radars sense laser light reflected from the target. A small corner reflector affixed to the target would produce a bright glint of reflected light, as would other corner reflectors launched on sounding rockets, ejected from the target, or attached to the target by extendable booms. These proliferated corner reflectors might force the beam weapon to attack them all.

The homing sensor of a kinetic energy interceptor could be susceptible to spoofing, depending on its type.

Jamming satellite-to-satellite communications crosslinks is probably *not* an effective offensive tactic, since the links would have narrow beamwidths, requiring the jammer to locate itself directly between the two satellites; and wide bandwidths, requiring high jammer power.

5.4 SHIELDING

A degree of shielding from lethal effects is practical for all but the kinetic energy weapons but involves in each case different methods suited to the different physical principles at work. At the same time, large uncertainties plague all lethality estimates, and further testing and study will be needed before firm answers can be given for any of the systems. For thermal kill with a laser, a solid booster designed with some attention to a laser threat can probably easily be made to withstand 10 kJ/cm^2. Application of a gram or so of heatshield material on each square centimeter of booster skin can probably triple this hardness, and spinning the booster enhances hardness by another factor of three. Heatshield material is ablative, meaning that when heated it burns off, carrying away the heat in the combustion gases rather than conducting it through to the missile skin underneath. A factor of nine increase in hardness requires the defensive laser to dwell on the booster nine times as long or to approach within a third of the range. Though hardening a new booster from scratch is clearly easiest, there is no serious impediment to retrofitting ablative coatings on existing boosters. Applying a gram per square centimeter of ablative material to the entire body of the MX missile would require removing several RVs from the payload, since the coating would weigh well over 1,000 kg.

An interesting possibility, requiring further study, would involve injecting into the atmosphere or producing from atmospheric gases, either throughout the ICBM flyout corridors or in the vicinity of individual boosters, smoke or laser absorbing molecules. Likewise, dust clouds raised by groundburst weapons (delivered by cruise missiles or by ICBMs that "leak" through the defense) might cause serious propagation problems for the ground-based laser scheme.

Hardening to an x-ray laser involves quite different physical principles. Recall that the x-ray energy is deposited in a paper-thin layer of the booster skin. The superheated layer explodes, applying an impulsive shock to the booster. Obviously a paper-thin shield between the booster and the laser will stop x-rays from reaching the booster wall. But the problem then becomes the debris from the exploding shield. One can easily show by calculation that the debris applies virtually the same impulse to the wall of the booster as would result from direct impinging of the x-rays! A number of schemes can be devised to divert the debris from striking the booster, but these require more study to implement in practice. One factor acting in favor of the shield designer is that the booster is not vulnerable to x-ray attack until it leaves the atmosphere. The lightweight shields therefore do not have to be designed to suffer large drag forces.

The neutral particle beam presents a third distinct type of hardening problem. The energetic beam particles penetrate into the target, and several centimeters of lead would be required to stop them. Since the beam cannot penetrate very far into the atmosphere, only the upper booster

stages need be hardened. But if the third stage, say, of the MX were covered with a few grams per square centimeters of lead, the shielding alone would weigh as much as several RVs. On the other hand, if the neutral particle beam is only designed to disrupt or damage sensitive electronics, but is not powerful enough to do damage to other parts of the missile, only the sensitive components need be shielded. The weight penalty then becomes small.

It is possible that the offense can extend the protection of the upper atmosphere against the neutral particle beam by exploding a few nuclear weapons at moderate altitudes before the beam can reach them. The detonations heat the air, which rises, effectively elevating the altitude at which the neutral beam is stripped of its remaining electron and bent in the geomagnetic field. This phenomenon is called atmospheric heave. It is as yet unresolved whether atmospheric heave will loft enough air to make a difference to the engagement altitude of the x-ray laser.

5.5 DECOYS

There is no way for a decoy booster to mimic closely the hot exhaust plume of an ICBM booster except by burning a similar rocket stage. One can add chemicals to the propellants to brighten a small booster's plume and dim the ICBM's, but as a first approximation a faithful decoy must be another booster.

Decoy tactics are therefore not as attractive for boost-phase intercept systems that use plume sensing as they are for midcourse and reentry defenses, where large numbers of cheap, lightweight decoys can be carried with negligible offload of RVs. Still, the usefulness of a decoy depends not on how expensive the decoy is, but on how the cost of the decoy compares to the cost of the defense that intercepts it. Booster decoys would not be nearly as expensive as true ICBMs, since they carry no warheads or precision guidance system, they need not be highly reliable, and they might not need to be based in underground silos but can be deployed above ground next to the ICBM silos.

Some of the boost phase intercept systems must grow in the number of their deployed battle stations in direct proportion to the number of Soviet boosters. Deploying one decoy (with a dummy payload) next to each of the 1,400 Soviet ICBM silos might cause the United States to have to double the number of battle stations overhead (and thus worldwide, multiplying by the absentee ratio) to handle the extra traffic. If the defensive battle stations were at all expensive, this would be an unpleasant prospect for the United States.

Many directed energy schemes would not rely on plume sensing alone (see Section 4.1). Decoy tactics against laser radars (including corner reflectors; see Section 5.3) might be much easier for the offense to implement than mimicking the booster plume.

5.6 SALVO RATE

The worst-case attack for all the boost-phase intercept schemes is massive, simultaneous launch of all Soviet ICBMs. The defensive satellites over the Soviet silo fields at the moment of launch then have to handle the entire attack.

A more leisurely salvo rate would allow laser and particle beam defenses that have to dwell on their targets more time to handle more targets. Slow attack also allows pop-up defenses to climb to intercept position. An attack drawn out 10

minutes or longer allows fresh defensive satellites to move along their orbits into position overhead, replacing depleted satellites. The orbital period of satellites in low earth orbit is about 90 minutes. If there are 8 to 10 satellites in each ring of the defensive constellation, satellites replace one another every 10 minutes or so.

An exception to this simultaneous-launch worst-case analysis is the x-ray laser, which delivers all its energy in an instant.

There would seem to be few military penalties for the Soviet Union to adopting plans to launch all their ICBMs in large attack within a few minutes. Indeed, if one of their objectives is to destroy U.S. ICBMs in their silos, rapid attack would be the best Soviet choice. Some, though not all, of the successful attacks that could be mounted on Closely Spaced Basing (Densepack) for MX involve very slow or intermittent salvo rates, however.

More importantly, in many circumstances the Soviets might wish to launch only a fraction of their ICBM force. A U.S. defense deployment too small to intercept all boosters in a massive attack would still be able to handle a small attack. A light defense might therefore establish a "threshold" of attack intensity below which Soviet boosters would face intercept. This prospect is discussed further in Section 9.

5.7 OFFENSIVE BUILDUP

The most straightforward way for the offense to compete with the defense is to grow in size. If for every new ICBM added to the Soviet arsenal, the U.S. defensive satellite constellation must be augmented at comparable or greater cost, the Soviets could challenge the United States to a spending race to their net advantage. On the other hand, if the defensive buildup is cheaper than the offensive buildup, the defense forces the offense either to accept limitations on its penetration or to resort to qualitative changes in its arsenal.

As an illustrative example of such a cost tradeoff, consider the hypothetical HF chemical laser system described in Section 3.1. Each laser in that system requires 1.7 seconds of dwell time to destroy a booster. During the 200 seconds of boost, each laser overhead can therefore destroy 120 boosters. But for each laser overhead, 32 are needed worldwide. Suppose now that the Soviets deploy, in one region of the U.S.S.R., 1,000 Midgetman missiles at a cost of 10 to 20 billion U.S. dollars (see Section 2). The U.S. defense now needs to be "beefed up" with addition of $(1{,}000) \times (32)/120 = 270$ laser battle stations. A tradeoff of more than one complex U.S. satellite, launched and maintained on orbit, for every 4 Soviet boosters (or decoy boosters) deployed on the ground would certainly appear to be a losing proposition for the United States. This is true even though the hypothetical HF laser system represents a very favorable outcome of laser technology.

Note that Soviet deployment of new ICBMs in one region of the Soviet Union, within coverage of only a single U.S. satellite, gives them the best leverage in the cost exchange.

5.8 NEW TARGETING PLANS

Truly efficient ICBM defenses would presumably force upon the superpowers a stricter attention to targeting priorities. With thousands of warheads in today's arsenals able to be literally lobbed into any target area unimpeded, the superpowers have less need to be discriminating or parsimonious in their nuclear targeting. Such a shift might have both desirable and undesirable

consequences. For example, the offense might decide that in view of the cost of countermeasures it could no longer afford to threaten the other side's ICBM silos. The warheads "freed up" from the countersilo mission might then be dedicated to heavier targeting of other aimpoints (perhaps cities) as a hedge against poor penetration. How the superpowers would greet these hypothetical defenses is not clear, but it is probably quite wrong to imagine future defenses acting against offensive forces targeted according to the war plans of today.

5.9 OTHER MEANS OF DELIVERING NUCLEAR WEAPONS

One additional Soviet response to an efficient defense against their ICBMs would be increased emphasis on submarine-launched ballistic missiles (SLBMs), bombers, cruise missiles, and whatever novel methods time and ingenuity might in the future devise for introducing nuclear weapons to the United States. As defenses forced up the cost-per-delivered-warhead of ICBM forces, these other methods would become relatively more attractive. Though they would sidestep the BMD, these delivery means have higher pre-launch survivability than ICBMs, and bombers and cruise missiles have longer times of flight. These attributes are usually seen as "stabilizing." Shifting the emphasis of the arms competition away from ICBMs is therefore sometimes viewed as adequate payoff for the BMD effort.

SLBMs would obviously be vulnerable to the same boost-phase weapons as ICBMs. The same worldwide coverage, reflected in the absentee ratio, that plagues the anti-ICBM cost exchange means that orbiting boost-phase defenses threaten SLBMs the world over. However, midcourse and terminal tiers of a layered defense would in general have much less capability against SLBMs, because of the latter's short time of flight, possibly depressed trajectory, and uncertain direction of attack. Thus SLBMs could conceivably enjoy greater penetration of a layered defense than ICBMs.

If one takes an optimistic view of emerging defensive technologies, or if one contemplates technological "breakthroughs," it is at least conceivable that such developments will spawn new ways of delivering or aiding the delivery of nuclear weapons as well as new ways of interdicting them.

Section 6
A WORD ON "OLD" BMD AND "NEW" BMD

No one knows whether directed-energy weapons can be built with the characteristics assigned to the hypothetical systems of Section 3. Even if such systems can be built, it is not clear that their performance will match, much less exceed, the performance of terminal and midcourse BMD systems in level of protection (attack price) and in cost relative to offsetting offensive improvements. The boost-phase BMD systems receiving so much attention today were a year ago at the periphery, to say the least, of technical discussion of missile defense. It is important not to lose sight of the status of traditional reentry and "advanced" (as they were called a year ago) "overlay" midcourse BMDs.

Naturally, the promise of the better-understood terminal and midcourse systems does not seem so grandiose, nor the flaws so clear-cut, as they do for the conceptual boost-phase defenses discussed in this Background Paper. Sounder technical assessments can be made of the "old" BMDs than of the "new" concepts. Rough concepts gloss over all the difficult design problems that inevitably limit achievable performance and turn up serious problems; nonetheless, identifying potentially unsolvable problems at this early stage of study does not mean they will remain insurmountable. BMD architectures incorporating boost-phase intercept are not known to be able to perform better, dollar-for-dollar, than BMD architectures incorporating only midcourse and reentry intercept. They are just not known to be worse. Terminal defense systems have been studied, designed, and tested for years, and it is generally agreed that such systems, acting alone, can enforce a modest attack price of between 2 and 8 RVs (perhaps equivalent to 20 to 80 percent of a booster) per defended aimpoint. Though their capabilities are modest, reentry and midcourse defenses suffice for modest defensive goals. There is no need to incur the technical risk of "new" boost-phase intercept schemes unless one aspires to levels of performance clearly beyond those possible with "old" concepts.

Many of the "new" concepts for boost-phase intercept are not new at all. They have been studied and discussed in one form or another for 20 years. Conversely, there are some new ideas for improving terminal and midcourse BMDs.[1] The spirit of technical optimism that accompanied the new emphasis on boost-phase intercept in the past year affected thinking about "old" BMD as well.

For terminal defense systems, the new features receiving attention are, first, non-nuclear warheads on interceptor missiles and, second, airplane-borne infrared sensors as supplements to ground-based radars. The principal benefit of non-nuclear intercept is that interceptors can be deployed nationwide without public concern about the safety of defensive nuclear warheads. Non-nuclear kill does not permit the defense to avoid all the disruptive effects of nuclear bursts, however, since the offense can still arrange for RVs to detonate when they sense interceptor impact ("salvage fuzing"). The miss-distance/weight relationship of the non-nuclear warhead requires the interceptor to approach more closely to the RV, and this in turn requires a homing seeker on the interceptor. Terminal homing obviously creates new opportunities for offensive countermeasures.

Airborne optical sensors obviously do not suffer radar blackout, but they can suffer the analogous problem of infrared redout. Decoy discrimination remains a problem, though it acquires some interesting new features. Details of these new aspects of terminal BMD are obviously classified. Though important, these aspects are fairly straightforward extensions of traditional techniques rather than revolutionary "breakthroughs."

New thought about midcourse defense focuses on alleviating the Achilles' heel of systems that use infrared sensing to support intercept in space: the ease with which the offense can accompany attacking RVs with clouds of decoys. One approach receiving attention is simply to cheapen the interceptor and shoot at everything, RVs and decoys alike. Another is to probe the attacking

[1] See Julian Davidson, "BMD: Star Wars in Perspective," *Aerospace America*, January 1984, p. 78.

objects with an active sensor, rather than relying on their thermal emissions, in the hope of discriminating RVs from decoys. Some of these "active discrimination" schemes are complex and expensive and might in turn be susceptible to offensive spoofing. A third aid to discrimination is the boost-phase defensive layer itself, which might constrain the number and type of penetration aids the offense could mount on each booster in addition to reducing the total number of objects approaching the midcourse tier. Fourth, extensive use of space-based sensors would allow the defense to observe penetration aids throughout their flight (including during deployment from the bus) rather than just as they approach the United States. It remains unclear whether these techniques will be worth the costs and new countermeasures they would bring to the defense.

Section 7
A HYPOTHETICAL SYSTEM ARCHITECTURE

Most analysts of boost-phase BMD assume that midcourse and terminal BMDs will augment the boost-phase layer. This section assembles a hypothetical layered defense system *in toto*. This system is *purely illustrative*, taking current BMD concepts at their face value and conveying a concrete image of the defensive architectures analysts apparently have in mind when they speak of nationwide defense. Obviously there are many choices for such a "strawman" system. The particular system described below was chosen for its illustrative value and not because it represents some "most plausible" alternative. It would be meaningless to suggest a "front runner" in the present state of study and technology development. Rather, the purpose of this example is to show how the layers interact and to indicate the overall scale of the deployments contemplated, without implying that anything remotely like it ever could or would be built.

A defense with several layers presents the offensive planner with some of the variety of problems that afflicts the BMD designer, who never knows in advance which attack tactic or countermeasure the offense will choose and must include responses to all of them in the system design. Layered defense forces the offense not only to develop responses to all the layers, but to develop responses that can be accomplished simultaneously. Thus, for example, the method chosen to avoid boost-phase intercept must not prevent deployment of lightweight midcourse decoys. The synergistic effect of the several layers obviously works strongly in the defense's favor.

Nonetheless, one must compare the performance of a three-tiered defense to the performance of a two-tiered defense of the same cost. Thus it should be no surprise if a $200 billion system with boost (and possibly even post-boost), midcourse, and terminal layers performs better than a $50 billion system with no boost phase layer. The correct questions are whether the additional $150 billion is worth the extra performance, and whether spending the $150 billion on more terminal and midcourse defense would in fact be a better investment.

Occasionally one sees a simplified leakage calculus applied to layered defense. The calculus assigns a "leakage" of, say, 25 percent (0.25) to the boost phase layer, 15 percent to the midcourse layer, and 10 percent to the reentry layer, deducing an "overall leakage" of 0.4 percent on the basis of the equation $(0.25) \times (0.15) \times (0.10) = 0.004$. Though the term leakage can be defined so that this calculus holds, the result actually bears little relation to the number of targets preserved by the defense. For one thing, a given defensive layer does not have an associated leakage *fraction* independent of attack size: the leakage fraction for each layer usually increases with attack size, most obviously (but not only) when the defensive arsenal becomes saturated. Second, the performance levels of the individual layers are not independent. For example, if the midcourse layer's interceptor arsenal is sized to handle only 25 percent of the attack, and the boost-phase layer works poorly and in fact allows 50 percent of the attack through, the midcourse layer obviously cannot display the same fractional efficiency against the attack of double the expected intensity. Conversely, improvements in one layer might improve performance of another: effective boost-phase or midcourse layers might force the offense to abandon the highly structured "laydowns" of RVs in space and time that limit a terminal layer's effectiveness. Third, the raw number or fraction of leaking RVs does not indicate the number or fraction of targets destroyed because of the tactics of preferential offense and defense. For these reasons, the leakage calculus is not a helpful way to encapsulate layered defense performance.

7.1 SYSTEM DESCRIPTION

The system design described below takes literally the goal of comprehensive nationwide defense. It seeks the capability (at least on paper) to engage all attacking Soviet missiles, whether targeted at cities, U.S. silos, or other military installations. Clearly the precise numbers and kinds of components in this description can be adjusted to suit any set of assumptions. The point of this description is merely to convey the flavor of these massive architectures. Most assumptions are favorable to the defense.

Suppose that at some time in the future the Soviet ICBM arsenal still consists of 1,400 boosters, as it does today. For simplicity, suppose further that each booster is an MX-sized solid propellant missile carrying 10 RVs and that all silos are located in one large region of the U.S.S.R. The boosters are not specially shielded against lasers, but some care in their design has given them an effective hardness of 10 kJ/cm^2, and they are further spun during ascent. Each booster carries a small number of decoys, but their small number is offset by the decoys' high fidelity. Each RV is accompanied by 9 lightweight infrared replicas and 1 high altitude reentry decoy. (This is a very modest penetration aid loading. One can assume larger numbers with perhaps poorer fidelity, chaff and aerosols, etc.)

The hypothetical U.S. defense system comprises both HF chemical laser battle stations and x-ray laser battle stations for boost-phase intercept, land-based midcourse interceptors carrying LWIR homing vehicles (the so-called "Overlay"), and land-based high-endoatmospheric homing interceptors with non-nuclear warheads for reentry intercept.

Table 7.1.—Hypothetical Future U.S. Defense Designed for Nationwide Protection Against Hypothetical Future Soviet Offense

U.S. Defense	Soviet Offense
5 warning satellites	1,400 MX-like ICBMs deployed in one region
160 HF laser satellites	10 RVs per ICBM
160 laser radars	9 midcourse decoys per RV
900 x-ray laser satellites	1 reentry decoy per RV
900 MWIR trackers	
28,000 midcourse intercept vehicles and boosters	
20 LWIR satellites	
75 radars	
140,000 terminal non-nuclear interceptors	
25 aircraft with LWIR sensors	

SOURCE: Author.

The HF chemical laser system resembles that described in Section 3.1, except that it has only five 20 MW lasers at each position in the 32-position constellation, for a worldwide total of 160. At a range of 2 Mm, a laser must dwell on each spinning booster for 5 seconds, so each laser at this range can handle 30 simultaneously launched boosters if defense begins 30 sec into the 180 sec boost phase of an MX-like booster. The five lasers overhead the Soviet silos at any one time can therefore only handle 150 of the 1,400 Soviet ICBMs. For small Soviet attacks, however, this non-nuclear boost-phase layer suffices.

For a large-scale Soviet attack, the United States deploys in addition a nuclear boost-phase system of x-ray lasers. A "perfect" laser with characteristics such as those derived in Section 3.3 can intercept ideally about 50 boosters at 4 Mm range. Therefore 28 lasers need to be in position over the Soviet silos at any time to handle a massive launch, giving a worldwide total of 900 (absentee ratio 32).

Warning for the boost-phase system is provided by MWIR warning satellites in synchronous or supersynchronous orbits. Also, each of the 160 HF laser battle stations has an MWIR telescope with 4 m mirror and an ultraviolet or visible ladar with 2 m mirror for pointing. Each x-ray laser is accompanied by an MWIR telescope tracker with 1 m mirror.

The 1,400 Soviet boosters carry 14,000 RVs, 126,000 midcourse decoys, and 14,000 reentry decoys. The United States assumes that only 10 percent of the boosters will survive the boost phase defense, so the midcourse tier needs to face 1,400 RVs and 12,600 midcourse decoys. The midcourse interceptors are given extremely long range, so only two bases are needed to cover the entire United States. However, each base must be prepared to absorb the entire attack, since the Soviets could target one half of the country more heavily than the other. There-

fore the United States needs 14,000 midcourse interceptors at each base, for a total of 28,000 interceptors. A constellation of 20 satellites with large LWIR sensors provide long-range acquisition and target assignment to these interceptors.

The United States next estimates that 90 percent of the RVs that enter the midcourse layer will be successfully intercepted. The terminal defense must handle 140 RVs plus 140 reentry decoys.[1] The reentry decoys are, by assumption, completely faithful in mimicking the signatures of RVs as seen by ground-based radars and aircraft-borne infrared sensors during early reentry—large decoy numbers have been sacrificed for this high fidelity. If the U.S. defense takes literally its charge of nationwide defense, it must be prepared to make 280 intercepts anywhere in the country.

[1]The number of reentry decoys the terminal system must face actually depends on whether the decoys fool the midcourse as well as the terminal system's sensors and on whether the terminal and midcourse layers cooperate in discrimination. Suppose first that the reentry decoys look like RVs (and therefore also like midcourse decoys) to the midcourse layer's sensor. Then the midcourse layer will intercept 90 percent of them (more midcourse interceptors must be bought to do this). If, on the other hand, the midcourse layer correctly identifies the reentry decoys as non-lethal objects, it might (a) not intercept them, requiring the terminal layer to plan to face 140 RVs plus 1400 reentry decoys, increasing enormously the required arsenal of terminal interceptors; (b) intercept them, in which case a reentry decoy is a perfect midcourse decoy, making possible a new threat—large numbers of midcourse decoys that look like reentry decoys rather than RVs; (c) radio the information, object-by-object, to the terminal defense fields.

Each terminal defense site consists of a phased-array radar and a number of high altitude non-nuclear interceptors. Additional target acquisition support is provided by a fleet of aircraft patrolling the U.S. periphery, carrying LWIR sensors. Each radar has a radius of action of over 200 km, so 75 or so cover the entire United States. However, an interceptor only covers an area about 50 km in radius. Since the area of the United States is about 8 million square km, over 1,000 interceptor sites would be needed for nationwide coverage. Should the defense have to reckon with intensive Soviet attack on some regions and no attack on others? Clearly, yes. But equipping each interceptor site to handle all 280 objects passing through the first two layers would require buying 280,000 interceptors! The defense would need to buy this many interceptors if it wanted to claim the literal capability to engage *all* Soviet RVs, *no matter* where they landed. Suppose, then, that the United States hopes for a more evenly distributed Soviet attack and deploys just half of the arsenal needed for complete coverage—140 interceptors per region. One radar might not suffice to handle all the RV traffic in its sector if the Soviets attack some sectors preferentially, but the United States nonetheless buys just 75 radars. Five aircraft on patrol at all times requires a backup fleet totalling perhaps 25.

Table 7.1 summarizes the offensive and defensive deployments.

7.2 ASSESSMENT

It is obviously not possible to assess the performance of a system, such as the hypothetical layered defense described above, whose components are not (and in many cases cannot be) designed today, much less assembled in an overall architecture. It is nonetheless worth sketching, in the illustrative spirit of this section, the issues that would require analysis if anything resembling Table 7.1 were ever proposed for deployment.

The first issue concerns the cost of the improvements to the system needed to offset growth in the Soviet ICBM arsenal—that is, the cost exchange ratio. The number of defensive weapons is proportional to the number of Soviet ICBMs. If the Soviets were to double the size of their ICBM arsenal, the United States would need to double the number of its x-ray lasers and interceptor missiles. (The number of sensors would generally have to increase also, though perhaps not in proportion to the Soviet buildup. The number of HF lasers could remain the same if the United States continued to intend to use this nonnuclear boost-phase layer to engage only Soviet attacks of 150 boosters or less.) Comparison of the two columns of Table 7.1 indicates that an arms race of Soviet offense and U.S. defense seems certain to favor the Soviet side greatly.

A second issue concerns the huge inventories of midcourse and reentry interceptors needed for nationwide defense. The arsenal of reentry interceptors shown in Table 7.1 is in fact only half the size needed for literally complete nationwide coverage, as remarked above. The cause of these large interceptor inventories—besides the obvious presence of decoys—is twofold: first, the low leakage sought by the defense precludes preferential defense, the tactic that makes silo defense so much more economical; and second, the limited coverage of each interceptor battery makes preferential *offense* possible for the attacker. The goal of nationwide low-leakage defense therefore forces the BMD system to forfeit the two sources of leverage that have historically impelled BMD towards the technically modest mission of defending compact silo deployments to relatively low survival levels.

Soviet countermeasures—besides straightforward buildup of ICBMs—is a third issue. The particular boost-phase layers described above are susceptible in varying degrees to all of the countermeasures described in Section 5, and the midcourse and reentry layers to their respective sets of countermeasures.

Defensive coverage against submarine-launched ballistic missiles (SLBMs) is a fourth issue. The boost-phase layers can intercept SLBMs launched from all points on the globe. Though the average range from laser satellite to booster is larger at equatorial and polar latitudes than at the mid-latitudes where Soviet ICBMs are located, the number of SLBMs that could be launched in a short time from each ocean area is also much smaller than the huge number of ICBMs that could lift off simultaneously from the U.S.S.R. Even the chemical laser deployment alone might suffice for boost-phase coverage of SLBMs. The midcourse and reentry layers, however, would in general not perform as well against SLBMs as against ICBMs. SLBM trajectories present bad viewing angles to the midcourse layer's LWIR sensors, and the short timeline limits interceptor coverage. The reentry layer would need to be augmented with more airborne sensors and more radars (or radar faces) to cover attack from the ocean. In general, then, a layered system optimized for ICBM defense could not necessarily handle SLBMs as well.

Section 8
DEFENSIVE GOALS I: THE PERFECT DEFENSE

No assessment of whether a defensive system "works" or not is meaningful without a clear and direct statement of the goal of the deployment. Though there has been much discussion of the feasibility of boost-phase BMD, proponents and skeptics alike frequently leave unstated the standards against which they are judging the technical prospects. A "successful" BMD deployment could be defined as anything from a truly impenetrable shield, to a silo defense that merely costs less to build than it costs the Soviets to overcome, to a tangled deployment that just "creates uncertainty" for the attacker.

The most ambitious conceivable goal for BMD would be to take at literal face value the words of President Reagan in his so-called "Star Wars" speech of March 23, 1983, when he called for development of a defense capable of making nuclear weapons "impotent and obsolete."[1] It is not clear that the President intended his words to be taken literally, nor that the Administration or anyone else is suggesting the United States seek a truly perfect or near-perfect defense.[2] Nonetheless, so much writing and debate focuses on this prospect, and its importance is so great, that it is taken up in this section. Section 9 treats the many other possible goals for less-than-perfect defenses.

There is some confusion in the literature about the use of the term "mutual assured destruction" (MAD) in connection with the notion of perfect defense. In common strategic parlance, MAD refers to the *technological circumstance* of mutual vulnerability to catastrophic damage from nuclear weapons, not to a *chosen policy* to promote such vulnerability. There is a strategic school of thought that advocates a policy usually called "minimum deterrence," maintaining that the capability for assured destruction of Soviet society is the *only* requirement of U.S. strategic forces. However, many experts believe that effective deterrence and other national security objectives require nuclear forces capable of many other tasks than assured destruction. This section addresses itself to the question of whether MAD is an avoidable technological circumstance, *not* to whether minimum deterrence is a prudent strategic policy.

A sensible start at judging the prospect for near-perfect defense must involve two steps: first, an exact statement of what perfect defense means in the context of attack on society with nuclear weapons; second, some way of gauging the likelihood of success when the technological future cannot be accurately predicted.

---

[1] *Weekly Compilation of Presidential Documents*, Vol. 19, No. 12, March 28, 1983, pp. 447-448. The text of the relevant part of the speech is reprinted as Appendix A.

[2] Defense Secretary Caspar Weinberger appeared to confirm a literal interpretation in a March 27 interview on NBC's *Meet the Press*, when he said (as reported in the *Baltimore Sun*, March 28, 1983, p. 1):

> The defensive systems the President is talking about are not designed to be partial. What we want to try to get is a system which will develop a defense [sic] that is thoroughly reliable and total. I don't see any reason why that can't be done.

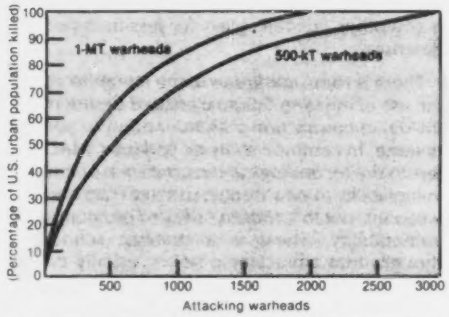
Later, the Defense Department stated that the purpose of the President's initiative was not to save lives, but to deter war. Responding to the "Congressional Findings" section of the proposed "People Protection Act" (H.R. 3073, 98th Congress, 1st session) which stated, "The President has called for changes in United States strategic policy that seek to save lives in time of war," Defense Department General Counsel William H. Taft IV wrote:

> It is clear that portions of the "Congressional findings" section [of H.R. 3073] vary from the purpose of the President's initiative. First, and most importantly, the purpose of the President's initiative is to strengthen our ability to deter war by, as the President has said, " . . . rendering [ballistic missiles] impotent and obsolete." In short, the purpose of the Administration's policy is to reduce the likelihood of war. The finding [of H.R. 3073] that the purpose is to "save lives in time of war" departs from our goal of deterring war.

Dr. Charles Townes, a frequent adviser to Secretary of Defense Weinberger and leader of two DOD task forces studying basing modes for the MX missile, said that a perfect defense proposal is "quite impractical. There is no technical solution to safeguarding mankind from nuclear explosives." (*New York Times*, April 11, 1983, p. 14).

8.1 NUCLEAR ATTACK ON SOCIETY

Figure 8.1.—The Effect of Attack Size on the Extent of Prompt Fatalities in U.S. Urban Areas



Note: Aimpoints chosen to maximize prompt human fatalities. U.S. urban population is estimated to be 131 million, as in the 1970 census.

SOURCE: Arms Control and Disarmament Agency, *U.S. Urban Population Vulnerability* (ACDA, 1979), quoted in Arthur M. Katz, *Life After Nuclear War: The Economic and Social Impacts of Nuclear Attacks on the U.S.* (Ballinger, 1982). Adapted from Ashton Carter and David N. Schwartz, eds., *Ballistic Missile Defense* (The Brookings Institution, 1984), p. 188.

Suppose one wants to take literally the goal of removing from the hands of the Soviet Union the ability to do socially mortal damage to the United States with nuclear weapons, so that the Soviet Union no longer possesses the elemental capability of assured destruction.) What does this mean?

Figure 8.1 shows how the percent of the U.S. urban population (about 130 million people in the 1970 census) killed promptly increases with the number of Soviet warheads detonating over U.S. cities. No such curve of the effects of nuclear attacks on cities should be taken as anything but suggestive: uncertainties are very great in such estimates, and no attempt has been made to reflect long-term and indirect effects of the detonations.[3] The curve also accounts only for fatalities, not for the many additional people injured. If one wishes to account for the possibility of civil defense evacuation, then the curve should be taken to represent not the number of people killed, but the number of people whose homes, businesses, historic monuments, schools, and places of worship have been destroyed.

No one supposes that the Soviet Union actually chooses aimpoints for its nuclear weapons with the goal of maximizing human fatalities, as has been done in preparing Figure 8.1. If the United States possessed a defense capable of intercepting all but a few of the 8,000 to 10,000 Soviet nuclear warheads, however, the Soviet Union might retarget its forces to wreak the most destruction possible with its few penetrating warheads. At any rate, any defense promising U.S. society genuine immunity from nuclear attack must reckon with Soviet determination to keep its arsenal from being "rendered impotent," and therefore with targeting plans contrived to do the most damage to the fabric of U.S. society.

Where on the curve of Figure 8.1—after how many detonations—does one locate the boundaries of "assured destruction," "assured survival," "impotent and obsolete," and similar phrases? Clearly there is no analytical prescription for these boundaries: they are the subject of a broader human judgment. 500 half-megaton warheads kill half the urban population, injure most of the rest, and totally destroy all American cities and large towns. Just 5 megatons, about one two-thousandth of the Soviet arsenal, detonated over the 10 largest U.S. cities could kill several million people and wound over 10 million more.

For the sake of discussion, we shall use 100 megatons—about 1 percent of the Soviet Union's arsenal and 1.5 percent of its ICBM force—as the level of penetration for which a defense would

[3]For discussion of some of the effects of nuclear weapons on population and cities, see: U.S. Arms Control and Disarmament Agency, *An Analysis of Civil Defense in Nuclear War* (ACDA, 1978); OTA, *The Effects of Nuclear War* (GPO, 1979); ACDA, *The Effects of Nuclear War* (ACDA, 1979); "Economic and Social Consequences of Nuclear Attacks on the United States," prepared for the Joint Committee on Defense Production, 96 Cong. 1 sess., 1979; J. Carson Mark, "Global Consequences of Nuclear Weaponry," *Annual Review of Nuclear Science*, Vol. 26 (1976), pp. 51-87; National Research Council, *Long-Term Worldwide Effects of Multiple Nuclear-Weapons Detonations* (National Academy of Sciences, 1975).

be judged "near-perfect." This definition is obviously very generous to the notion of perfect defense, since most people would presumably not regard 100 megatons of explosive force as "impotent and obsolete." Still, it is a definite reference for assessment.

8.2 THE PROSPECTS FOR A PERFECT DEFENSE

There is not and cannot be any "proof" that unknown future technologies will not provide near-perfect defensive protection of U.S. society against Soviet ICBMs. The question that needs to be answered is whether the prospects for near-perfect defense are so remote that such a notion has no place in reasonable public expectations or national policy. It is, after all, not provable that by the next century the United States and U.S.S.R. will not have patched up their political differences and have no need to target one another with nuclear weapons. The issue of the perfect defense is unavoidably one of technical judgment rather than of airtight proof.

Four misapprehensions seem common among non-technical people addressing the prospects for perfect defense.

The first misapprehension is to equate successful technology development of individual *devices*—lasers, power sources, mirrors, aiming and pointing mechanisms—with achievement of an efficient and robust defensive *system*. Millionfold increase in the brightness of some directed-energy device is a necessary, but is far from a sufficient, condition for successful defense. In the early 1960's, intercept of RVs with nuclear-tipped interceptor missiles was demonstrated—"a bullet could hit a bullet"—but 20 years later systems incorporating this "kill mechanism" are still considered relatively inefficient. In general, skeptics about the future of space-based directed-energy BMD do not confine their doubts to, or even emphasize, unforeseen problems in developing the individual components.

A second misappprehension arises in attempts to equate BMD development to past technological achievements, such as the Manhattan project's atomic bomb or the Apollo moon landings.[4] The technically minded will recognize a vital difference between working around the constraints imposed by nature, which are predictable and unchanging, and competing with a hostile intelligence bent on sabotaging the enterprise. A dynamic opponent makes of BMD, first, a more difficult design problem, since the offense constructs the worst possible barriers to successful defense; and second, not one problem but many problems that need to be sidestepped simultaneously in the design, since the designer cannot be certain which tactics the offense will use.

A third misapprehension concerns the prospect for a "technological breakthrough" that would dispel all difficulties. Such breakthroughs are not impossible, but their mere possibility does not help in judging the prospects for the perfect defense. For one thing, an isolated technological breakthrough creating a new defensive component would not necessarily alleviate the system issues—vulnerability, dependability, susceptibility to countermeasures, cost—that determine overall effectiveness. Second, one can just as easily imagine offensive "breakthroughs," sometimes involving the same technologies. Thus the x-ray laser, if it matures, might turn out to have been

[4]Defense Secretary Caspar Weinberger has written (*Air Force Magazine*, Nov. 1983):

> The nay-sayers have already proclaimed that we will never have such technology, or that we should never try to acquire it. Their arguments are hardly new . . . In 1945 President Truman's Chief of Staff, Adm. William Leahy, said of the atomic bomb: "That's the biggest fool thing we've ever done. The bomb will never go off, and I speak as an expert in explosives." In 1946 Dr. Vannevar Bush, Director of the Office of Scientific Research and Development said of intercontinental ballistic missiles, "I say technically I don't think anybody in the world knows how to do such a thing, and I feel confident it will not be done for a long time to come." These critics were proved wrong; what is more, they were proved wrong quickly.

better termed a breakthrough in strategic offense than a breakthrough in strategic defense.

A fourth misapprehension concerns the confidence with which predictions could be made about the performance of a complex system once in place. The "performance" of a system, as quoted in analyses, is the most likely outcome of an engagement of offense versus defense. Other outcomes, though less likely, might still be possible. Computing the relative likelihoods of *all* possible outcomes would be difficult even if one could quantify all technical uncertainties and statistical variances. Still, there would remain a residue of uncertainty about the performance of a system that had never been tested once in realistic wartime conditions, much less in a statistically significant ensemble of all-out nuclear wars. The defense would also have no chance to learn and adapt. In World War II, by contrast, air defense crews learned in raid after raid to inflict losses of several percent in attacking bombers. The only reason these modest losses assumed strategic significance was that they accumulated over many raids. Of course, the same uncertainties plague the offense as plague the defense. In general, the offense would tend to overestimate the defense's capability. This natural tendency toward "offense conservatism" is probably vitally important to the psychological and deterrent value of BMD as it is applied to less-than-perfect goals. For the perfect defense goal (as defined above), however, it would seem that the uncertainty weighs heaviest on the defense. To the reckless, non-conservative defense, a wrong estimate of defense performance spells the difference between safety and socially mortal damage (or between deterrence and war). The reckless offense, on the other hand, is presumed desperate enough to try to inflict such damage on its enemy and willing to accept the consequences: it stands to lose little if its estimates are wrong and the defense *does* work perfectly after all.

With these misapprehensions out of the way, and recognizing clearly that there can be no question of "proof," it would seem that four major factors conspire to make extremely remote the prospect that directed-energy BMD (in concert with other layers if necessary) will succeed in reducing the vulnerability of U.S. population and society to the neighborhood of 100 megatons or less.

1. **Near-perfect defense of society is much harder and more expensive than partial defense of military targets.** That is, the marginal cost exchange is much higher for near-perfect defense than for partial defense (see also Fig. 5.2). There are two reasons behind this well-known statement.

The first reason is illustrated schematically in Figure 8.2. In going from partial silo defense to perfect city defense, the BMD loses the leverage of preferential defense. Additionally, the offense gains the leverage of preferential offense against the terminal and midcourse layers with their limited geographic coverage, although *not* against the boost-phase layer. In Figure 8.2(a), the defense aims to save only 10 percent of the ICBM force, or one silo. Assuming perfect interceptors and adopting the tactic of adaptive preferential defense (using all its interceptors to save just one silo chosen randomly from the ten at the moment of attack), the defense concludes it needs to prepare to make one only intercept to counter the offense's 10 RVs. In Figure 8.2(b), the offense can focus all 10 of its RVs on any one of ten cities. The defense must prepare to make 10 intercepts for each city, buying a total of 100 interceptors, if it wants to try to save all the cities. If the Soviets double their RV arsenal, the United States must buy just one interceptor to satisfy the defense goal of Figure 8.2(a), but the United States must buy 100 interceptors to satisfy the defense goal of Figure 8.2(b). The cost exchange ratio is thus 100 times worse for the city defense, even though it uses the same technology as the silo defense.

The second reason why a near-perfect defensive goal shifts the cost burden in favor of the offense is that the offense can turn all its resources to improving or replacing just a portion of its ICBMs to sidestep the defense. The Soviet Union could therefore harden just 1 percent of its boosters, perhaps concealing exactly which ones were hardened. Moreover, it could deploy a few fast-burn boosters immune to x-ray lasers and neutral particle beams; build a few different ASAT de-

Figure 8.2

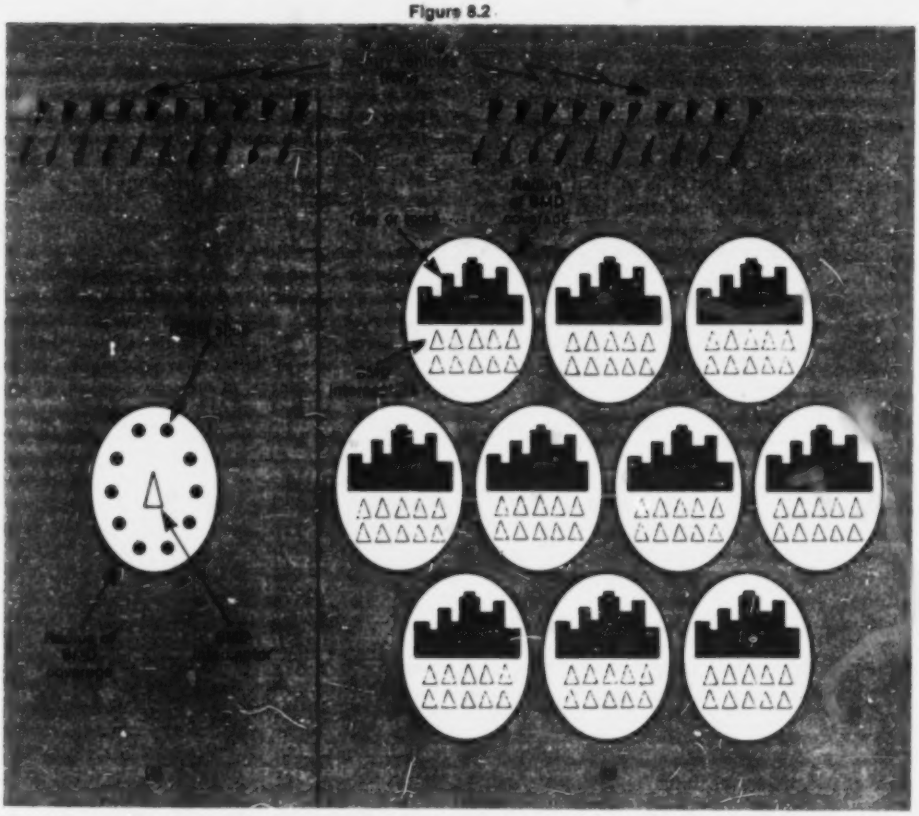


Figure 8.2. The cost to a U.S. reentry BMD to compete with increases in the size of the Soviet arsenal (the "marginal cost exchange") is much greater for near-perfect city defense (b) than for partial silo defense (a). In going from (a) to (b), the U.S. loses the leverage of preferential defense and the Soviet Union gains the leverage of preferential offense.

vices; and so on. More costly countermeasures are available to the offense if the countermeasures need only be implemented on a small scale rather than throughout the ICBM force. The offense can "experiment" with a number of different tactics with different portions of its force. The defense's costs also grow much larger if it must plan to face a *variety* of offensive countermeasures. In short, the defense must be able to stop all kinds of attack, but the offense only has to find one way to get through.

2. **For every defense concept proposed or imagined, including all of the so-called "Star Wars" concepts, a countermeasure has already been identified.** These countermeasures were enumerated in Section 5 and will not be repeated here. Three further generalizations about these countermeasures reinforce a poor prognosis for cost-effective near-perfect defense: 1) In general, the countermeasures could be implemented with today's technology, whereas the defense itself could not; 2) In general, the costs of the coun-

termeasures can be estimated and shown to be relatively low, whereas the costs of the defense are unknown but seem likely to be high; 3) In general, the future technologies presupposed as part of the defense concept would also be potent weapons for attacking the defense.

3. **The Soviet Union does not configure its nuclear missile forces today to maximize damage to U.S. society and population, but it could do so if faced with near-perfect U.S. defenses.** Targeting plans could focus exclusively on damaging cities. High missile accuracy would be unnecessary, lowering offense costs. Nuclear weapons could be designed to maximize harmful fallout. ICBM survivability measures—silos, racetracks, densepacks, etc.—would be unnecessary to a side striking first or possessing its own defense effective at saving many missiles (but not *all* cities); thus basing costs could be diverted to the city-kill goal. Presumably the Soviet Union would take these and any other measures necessary to prevent itself from being effectively disarmed by a U.S. defense, since otherwise it would be at its enemy's mercy.

4. **BMD by itself will not protect U.S. society from other methods of delivering nuclear weapons to U.S. soil or from other weapons of mass destruction.** Bombers and cruise missiles (and to a significant extent SLBMs and IRBMs) present very different defensive problems than ICBMs. Today the technical problems of air defense are no better resolved than the technical problems of BMD. Novel future offensive delivery vehicles can only be conjectured along with the future defense technologies discussed in this Paper. A desperate Soviet Union could introduce nuclear weapons into the United States on commercial airliners, ships, packing crates, diplomatic pouch, etc. Other methods of mass destruction or terrorism would be feasible for the U.S.S.R., including sabotage of dams or nuclear power plants, bacteriological attack, contaminating water, producting tidal waves with near-coastal underwater detonations, and so on.

Section 9

DEFENSIVE GOALS II: LESS-THAN-PERFECT DEFENSE

A host of less grandiose goals than perfect or near-perfect defense assume importance in certain theories about the workings of nuclear deterrence and the requirements of U.S. security. Thoughtful observers debate not just the feasibility of achieving these goals but the validity and importance of the goals as well. The urgency one attaches to these goals determines the costs, risks, and harmful side effects one is willing to incur to fulfill them. Assessing the wisdom of less-than-perfect defense thus involves a complex and subjective balancing of goals and risks, in which purely technical issues sometimes take a back seat. In discussion of perfect defense, by contrast, technical assessment is paramount. This section therefore calls up many issues of nuclear policy not subsumed under the title of this Background Paper, and no pretense is made here to complete treatment.[1]

Though various strategic goals for BMD can be distinguished in principle, in practice it might not be clear or agreed among all parties in the United States what the purpose of a proposed deployment actually was. Interpretations by the Soviet Union and other foreign nations of U.S. goals might be quite different yet.

[1]For a more complete treatment of the entire subject of BMD, see Ashton B. Carter and David N. Schwartz, ed., *Ballistic Missile Defense* (The Brookings Institution, 1984).

Those familiar with BMD design and assessment will recognize that stating a general *strategic* goal is not enough: the *technical* specifications are essential. For instance, it makes an enormous difference in silo defense whether the defense seeks to charge the offense a price of five RVs (or half a booster) or 10 RVs (one booster) per silo.

For goals requiring very modest performance, terminal and midcourse defenses might suffice. Since no one knows whether boost phase defenses, when better defined, will surpass or even equal traditional defenses in terms of leakage and cost exchange, there is no point in turning to exotic technologies to satisfy modest goals. Virtually all observers agree, on the other hand, that terminal and midcourse systems are unequal to the more demanding goals; for these goals one is forced to direct one's hopes to the promise of future technologies.

This section sketches various goals for less-than-perfect defenses and the strategic thinking that attaches importance to them. It then points out a number of side effects against which fulfillment of these goals needs to be balanced. This short section is no substitute for a comprehensive assessment of the pros and cons of BMD.

9.1 GOALS FOR LESS-THAN-PERFECT DEFENSE

1. **Strengthen deterrence by preventing preemptive destruction of retaliatory forces.** It is widely recognized that the Soviet Union will soon have, if it does not already, the combination of yields, numbers, and accuracy in its ICBM forces to destroy most U.S. Minuteman ICBMs in their silos. It is also widely agreed that vulnerable nuclear forces create unwanted temptations for both sides to strike first if war seems likely. The long and anguished search for survivable basing modes for the U.S. MX (Peacekeeper) ICBM has to date turned up no clear favorites when survivability is balanced against cost, technical risk, strategic effects, and environmental impacts.[2] BMD would substitute for or complement these other basing modes. By shooting down a fraction of the opponent's missiles, BMD would in effect "de-MIRV" ICBM forces.

Of course, turning to BMD to ease ICBM vulnerability is not without problems. One problem is the prospect of a compensating Soviet BMD.

[2]*MX Missile Basing*, Office of Technology Assessment, U.S. Congress, September 1981.

MX is presumably being bought and made survivable in the first place so that the U.S. can absorb a Soviet strike and retaliate with its ICBMs (in addition to its bombers and submarines) against Soviet targets. But modification or termination of the ABM Treaty to permit a U.S. defense would permit a Soviet defense as well. The surviving U.S. ICBMs guaranteed by the U.S. BMD might still not result in retaliatory damage to Soviet targets if these targets are defended by Soviet BMD. The U.S. BMD deployment, all bought and paid for, might therefore have been cancelled out by a Soviet counter-deployment.

Other elements of the U.S. retaliatory force comprise command and control links, bomber alert bases, and in-port submarines. Bomber bases, sub ports, and fixed command and control facilities are the worst type of target base for BMD to try to defend—a small number of high-value, soft, and interdependent targets. The important remaining category of mobile command and control facilities, on the other hand, does not easily lend itself to active defense with BMD.

2. **Strengthen deterrence by preventing the use of nuclear weapons as decisive military tools for high-confidence "limited" strikes on conventional forces.** This goal is associated with so-called "warfighting" strategies for nuclear weapons. According to analysts who hold this view, today's "offense dominated" world creates dangerous temptations to resort to nuclear weapons to accomplish militarily well-defined objectives. One can imagine warheads simply being lobbed unopposed into another country in any number or combination. Though surely the effects of these "limited" attacks on nearby communities would not be so well-defined, the effect on the opposing military machine might be truly dramatic, even decisive. This use of nuclear weapons in wartime is possible with today's unopposed offenses with considerable confidence and might therefore be tempting to the combatants. Such temptations threaten nuclear deterrence and should be eliminated. The goal of a comprehensive defense would be to make such limited attacks infeasible, or at least to complicate the offense's estimations of success to such a degree that it would not attempt an "experiment."[3] Analysts who favor this approach usually maintain that Soviet military doctrine inclines the Soviets towards a view of nuclear weapons as military tools to a far greater degree than is common in U.S. thinking.[4]

To take an explicit example (in this case of Soviet failure to deter the U.S.) of a "warfighting" scenario (chosen randomly from a great many possibilities), suppose NATO were at war with the Warsaw Pact, and the Soviets were resupplying their ground offensive through just 10 or so rail trunks from the Soviet Union through eastern Europe. Just 10 well-placed nuclear weapons (according to a hypothetical analyst considering this type of scenario) would cut off a large fraction of supplies coming to the front, slowing the Pact offensive and giving NATO vitally needed time to marshall its defenses. Wouldn't the United States be sorely tempted to use just a few ICBMs for this decisive intervention in the course of the war?

Analysts who recommend attention to warfighting scenarios and doctrines are surely aware of the profound difference between conventional and nuclear weapons, but they maintain that the threat of punishment through retaliation upon cities is not an effective deterrent in such scenarios. Wouldn't it be preferable if these scenarios were simply closed off by defensive technology?

Critics of this BMD goal object both to the warfighters' emphasis upon the risk of this type of scenario and to the assumption that defense would materially diminish that risk. In their view, myriad detailed chinks in the armor of deterrence can always be found, with or without defense, and worrying about them represents a loss of

[3]Presidential Science Adviser George A. Keyworth, II has stated (interview with *U.S. News and World Report*, April 11, 1983, p. 24):

> "The objective is to have a system that would convince an adversary that an offensive attack will not be successful. It has to be a very effective system, but it would not have to be perfect to convince a potential adversary that his attack would fail."

Dr. Robert Cooper, director of the Defense Advanced Research Projects Agency has also stated this view (*The New York Times*, Nov. 5, 1983, p. 32): "Even if only 50 percent of all incoming missiles were stopped, the Soviets could then have no confidence in the success of a first strike, and war would be more remote."

[4]*Ballistic Missile Defense*, op. cit., Chapter 5.

perspective on the basic difference between nuclear and conventional instruments of war. Besides, they say, suppose the effect of the Soviet BMD is to force the United States to attack each rail line with ten weapons instead of one to assure penetration: Is there truly a psychological divide between using 10 and 100 nuclear weapons, once the divide between 0 and 10 has been crossed? Third, would NATO not be adequately deterred by the prospect of Soviet retaliation with 10 of its nuclear weapons against 10 vital NATO targets? Last, suppose NATO used 10 cruise missiles, against which the BMD was powerless, instead of 10 ICBM RVs?

The persuasiveness of this second goal for less-than-perfect BMDs therefore depends on one's views of the roles and risks of nuclear weapons—views that are fundamental and deeply held. This goal is therefore one of the most controversial of all.

3. **Save lives.**[5] Another goal for BMD is purely humanitarian and seeks no military or strategic advantage. If the defense did not interfere too much with Soviet military targeting objectives (enough for the Soviets to try to overcome it), and assuming the Soviets have no explicit aim to inflict human casualties, the United States could expect some reduction in fatalities in a nuclear war even from a modest defense. This reduction would necessarily be limited, since Soviet military objectives include destruction of many targets collocated with population. BMD and civil defense measures would be mutually reinforcing.

Analogous discussion of civil defense has always revealed an inherent tension between the humanitarian objective of defense and a related strategic objective. The strategic objective seeks to reduce fatalities and damage in order to enhance U.S. "flexibility" in a crisis, to allow the United States to "coerce" the U.S.S.R. (or avoid coercion) from a position of reduced vulnerability, or to enhance U.S. ability to persist in its war effort despite receiving a Soviet nuclear strike. The supposed result of the BMD deployment is to allow the U.S. President, in dealing with the Soviet leadership in time of crisis, to be more willing or appear to be more willing to resort to nuclear war because the consequences to the United States are presumed smaller.

The coexistence of the humanitarian and strategic objectives for the analogous case of civil defense is apparent in the literature on civil defense. The Defense Department[6] has argued that the United States should have the same crisis relocation options as the U.S.S.R. for two reasons, one strategic and one humanitarian: 1) "to be able to respond in kind if the Soviet Union attempts to intimidate us in time of crisis by evacuating the population from its cities"; and 2) "to reduce fatalities if an attack on our cities appears imminent." Prominent scientists arguing for civil defense have also maintained that, "A nation's civil defense preparedness may determine the balance of power in some future nuclear crisis. . . . In our opinion, we must strive for an approximately equal casualty rate".[7] More recently, the High Frontier Study urging strengthened U.S. strategic defenses stated: "The protection of our citizens must be prime, but civil defense . . . would reduce the possibility that the United States could be coerced in a time of crisis".[8]

In practice, therefore, the humanitarian and strategic objectives are likely to be difficult to disentangle. Unlike the humanitarian objective, the strategic objective might stimulate a Soviet effort to put the same number of American lives at risk regardless of the defense. In this way, the Soviet Union could retain the strategic advantage that, by hypothesis, the BMD deprives them of. The issue then becomes the usual one of the cost-exchange ratio measuring the price to the Soviet Union of retaining its "advantage" relative to the price of the U.S. defense.

The Defense Department has stated that saving lives in time of war is not the purpose of President Reagan's BMD initiative.[9]

[5]This discussion borrows from the author's previous work in *Ballistic Missile Defense*, op. cit., Chapter 4.

[8]Daniel O. Graham, *The Non-Nuclear Defense of Cities: The High Frontier Space-Based Defense Against ICBM Attack* (Abt Books, 1983), p. 122.

[9]See footnote 8.2.

4. **Shape the course of the arms competition and arms control.**[10] One version of this goal sees the Soviet tendency to upgrade and proliferate existing ICBM forces as the principal impediment to arms control. By introducing BMD (or even discussing it), according to this view, the United States makes the Soviets unsure about the next step in the arms competition and thus undercuts the momentum of Soviet strategic programs, especially ICBM modernization. Though fast-burning Midgetman boosters might defeat boost-phase defenses, this argument goes, the slow-burning SS-18s and SS-19s will not. BMD might not be able to make all nuclear weapons impotent and obsolete, but it can make large Soviet ICBMs impotent and obsolete—something the U.S. has been trying to do for a decade. Perhaps efficient defenses will "force" the Soviets to emphasize submarines, bombers, and cruise missiles in their strategic arsenal to the same degree the United States does. (One problem with this line of argument is that by the time the defense is in place, present-generation Soviet ICBMs might already be replaced.)

Another line of argument holds that a major BMD initiative strengthens the U.S. negotiating position at START. An aggressive BMD program demonstrates U.S. technological prowess and hints at what the Soviets could face if this prowess were unleashed. It would seem that new BMD initiatives might not coexist easily with the reductions in offensive arsenals proposed by the United States in START, however. Since U.S. BMD is equivalent to attrition of the Soviet ICBM arsenal, any anxieties the Soviets feel at reducing the size of their missile inventories would, logically at least, be enhanced by a simultaneous U.S. BMD buildup. Politically, it would seem unlikely, though certainly not impossible, that a climate favorable to far-reaching offensive arms control would also foster an amicable dismantling of the ABM Treaty.

5. **Respond to Soviet BMD efforts.** Many analysts view with alarm Soviet strategic defense activities, including upgrading of the Moscow ABM, development of a transportable terminal BMD system, construction of a radar in apparent violation of the ABM Treaty, development of defenses against tactical ballistic missiles, incorporation of limited BMD capability in air defenses, and continued attention to other damage-limiting methods (civil defense, air defense, antisubmarine warfare, and countersilo ICBMs). A strong U.S. BMD research and development program might deter the Soviets from breaking out of the ABM Treaty and from continued encroachments on the Treaty's provisions. It is frequently noted that aggressive U.S. research into penetration aids and other methods for countering defenses might be an even more effective way to demonstrate to the Soviets that they would be ill-advised to overturn the ABM Treaty's "freeze" on missile defenses.

6. **Protect against accidental missile launches and attack from other nuclear powers.** These goals have been put forward several times in the past, most notably in the late 1960's when the Johnson Administration proposed the Sentinel ABM system to counter Chinese ICBMs, believed at that time to be fast-emerging. Neither goal figures prominently in today's discussion of BMD in the United States, though defense against Chinese, British, and French missiles could well loom larger in Soviet thinking. Emerging nuclear powers or terrorists would be unlikely to use ICBMs to deliver their small nuclear arsenals to the United States. BMD is therefore of little importance in staving off the threat to U.S. security posed by nuclear proliferation.

[10]Presidential science adviser George A. Keyworth, speech before the Washington chapter of the Armed Forces Communications and Electronics Association, as reported in *Defense Week* (Oct. 17, 1983):

> "Although the strategic defense program's goal would still be eventual deployment of a working system, we shouldn't overlook its potential beneficial impact on arms reduction as its progresses."

Richard DeLauer, Undersecretary of Defense for Research and Engineering, has said that an arms control agreement is needed to prevent the Soviets from overcoming a defensive system: "With unconstrained proliferation [of Soviet missiles], no defensive system will work." (Interview with *The New York Times*, May 18, 1983).

9.2 SIDE EFFECTS OF BMD DEPLOYMENT

The inevitable side effects of a major strategic initiative such as BMD might turn out to match, both in magnitude and in duration, the beneficial effects of satisfying the goal emphasized by the system's purveyors. The public and policymakers would therefore need to assess the net, long-term effect of adding BMD to the strategic equation, and not just the achievement of a certain discrete goal as if by surgical intervention. This section reviews the well-known list of BMD side effects. Many of these effects are detrimental to U.S. security and would need to be balanced against the benefits of fulfilling the modest goals of less-than-perfect defense. In making this assessment, it is impossible to ignore the many unknowns and uncertainties that make it impossible to compare today's world without BMD to a future world with BMD.

1. **First strike versus ragged retaliation.** It is frequently noted that BMD ends up being a better investment for the side that strikes first than for the side that retaliates. Weapon systems that create relative advantages to striking first in a crisis (rather than risking being struck while seeking a peaceful resolution) are defined to be "destabilizing." The side striking first uses its full arsenal in an organized penetration of the other side's defense; the retaliating side can only use its surviving arsenal in a possibly disorganized "ragged retaliation" against a forewarned and fully prepared defense.

Mitigating factors could in certain circumstances soften this classical statement of the destabilizing effect of BMD. First, truly effective defenses might prevent the first striker from destroying a substantial fraction of the other side's retaliatory forces. Second, with proper planning (involving post-attack retargeting and coordinated timing), the retaliating forces might still be able to mount a tailored, efficient strike. Third, there will seemingly always be a *relative* advantage to being the side that strikes first in a nuclear war, with BMD or without BMD; but this calculus of relative advantage is far from being the only factor in deterrence. Other stabilizing factors might be strengthened by BMD, offsetting this destabilizing factor. Thus BMD might also *discourage* temptations to strike first, by threatening to disrupt the attack.

2. **Soviet BMD.** A U.S. BMD deployment would seem very likely to stimulate a Soviet deployment. Even if the Soviets saw no compelling military rationale for following suit, political appearances could prove decisive. A Soviet BMD counter-deployment would obviously blunt U.S. offensive striking power, which the U.S. has been spending a great deal to build up. If the U.S. deployment sought to protect its ICBMs from preemptive destruction in their silos (Goal 1 above), the Soviet BMD might nonetheless nullify the U.S. ICBMs—this time in flight to their targets. Soviet BMD would also introduce a threat to U.S. SLBMs, which are today thought to be virtually immune to Soviet disruption and to be significantly advanced relative to their Soviet counterparts. If the U.S. deployment sought to prevent "limited" strikes by the Soviets Union (Goal 2), the Soviet BMD might in turn preclude a U.S. option to use nuclear weapons selectively and flexibly in support of its NATO allies—an option sometimes seen as central to NATO strategy. Clearly the actual effect of the Soviet BMD counterdeployment would depend upon its technical characteristics and the targets it defended.

3. **Demise of the ABM Treaty.** An arms control treaty obviously cannot serve as its own justification, and presumably virtually everyone would agree to the abandonment of the ABM Treaty the moment it ceased genuinely to serve the national security. In addition to its concrete provisions limiting BMD deployment, however, the ABM Treaty has unavoidably assumed a symbolic political meaning in the United States and, in different forms perhaps, in Europe and the U.S.S.R. The Treaty stands for a decade of arms control and attempts at superpower understanding about nuclear weapons. As a practical matter, it is impossible to overturn the Treaty's technical provisions without calling into question U.S. commitment to the whole fabric of the SALT/START process. This side effect would have to be weighed against the purely military and strategic

benefit (if there were, in fact, a net long-term benefit) of a U.S. BMD deployment.

4. **Allied and Chinese missile forces.** The nuclear missile forces of Britain, France and China are obviously a greater threat to the Soviet Union than to the U.S. Most analysts agree that the existence of these forces enhances U.S. security. But a major BMD initiative sparking widespread Soviet defense would in effect disarm our allies (to a degree depending on the nature of the Soviet deployment).

5. **Accompanying strategic programs.** A number of new weapon systems and strategic programs would be natural, though perhaps not necessary, accompaniments to BMD. On the offensive side, the U.S. would need to develop and deploy penetration aids against the Soviet BMD and improve its bomber and cruise missile forces to reflect added reliance on non-missile delivery vehicles. On the defensive side, the overall category of "strategic defense" comprises, in addition to BMD: nationwide air defenses against Soviet bombers and cruise missiles, defensive coverage against SLBMs, civil defense shelters and evacuation plans, and passive "hardening" of military installations and industrial facilities.

6. **Opportunity Costs.** The initial investment in BMD deployment, the inevitable follow-ons, and any accompanying strategic programs would make a substantial, permanent demand on the defense budget, competing with other nuclear forces and with conventional forces, not to mention with nonmilitary expenditures.

In a more fundamental sense, the transition from a world with a near-total ban on BMD to a world with BMD deployments is probably an irreversible change. Reimposing a defensive "freeze" after a period of unrestrained deployment, much less dismantling defenses and returning to zero, would involve all of the problems that attend upon arms control reductions at START today. Extra caution seems warranted where strategic actions cannot easily be reversed or recalled: the opportunity for a comprehensive ban on missile defense might not arise again.

7. **Bean counting.** Strategists, politicians, and diplomats place considerable emphasis on quantitative measures of the nuclear balance and on "proofs" that "parity" exists. Arms control negotiations also reduce themselves quickly to counting rules. It is unclear whether or how BMD should affect such "bean counting." For each U.S. battle station added to a defensive constellation, are the Soviets to be credited with fewer ICBMs, since the U.S. defense represents potential attrition of the Soviet force? How many Soviet interceptor missiles equals one U.S. laser? Whose estimate of the BMD's likely wartime performance—the defense's or the offense's—governs these counting rules? Experience indicates that these types of questions, however far-fetched and even preposterous they appear in prospect, in the end assume considerable perceived importance.

8. **Asymmetries.** The Soviet BMD deployment that could well follow U.S. deployment might not share the same defensive goal or the same technology, stimulating the usual anxieties about unequal intentions and capabilities. Defensive systems are also complex, leading different analysts to widely different conclusions about the likely wartime performance of the BMD systems on both sides. Moreoever the owner of the BMD, aware of all the system's hidden flaws, might credit it with little capability, whereas the offense planner will tend to give it the benefit of the doubt. Though some hypothetical future world with mutual BMD deployments might therefore appeal to one analyst or nation, another could easily have a completely different view of the technical and strategic "facts."

Section 10

PRINCIPAL JUDGMENTS AND OBSERVATIONS

1. **The prospect that emerging "Star Wars" technologies, when further developed, will provide a perfect or near-perfect defense system, literally removing from the hands of the Soviet Union the ability to do socially mortal damage to the United States with nuclear weapons, is so remote that it should not serve as the basis of public expectation or national policy about ballistic missile defense (BMD).** This judgment appears to be the consensus among informed members of the defense technical community.

Technical prognosis for such a perfect or near-perfect defense is extremely pessimistic because of the concentration and fragility of society; because all concepts identified as candidates for a future defense of population are known to be susceptible to countermeasures that would permit the Soviet Union to retain a degree of penetration with their future missile arsenal despite costly attempts to improve the U.S. defense; because the Soviet Union would almost certainly make such a determined effort to avoid being disarmed by a U.S. defense; and because missile defense does not address other methods for delivering nuclear weapons to the United States.

Mutual assured destruction (MAD), if this term is applied to a state of technological existence rather than to a chosen national policy, is likely to persist for the foreseeable future.

2. **The wisdom of deploying less-than-perfect ballistic missile defenses remains controversial.** Less-than-perfect defenses would still allow the Soviet Union to destroy U.S. society in a massive attack but might call into question the effectiveness of smaller, specialized nuclear strikes.

Certain theories about nuclear war maintain that such defenses could lessen the chances of nuclear war and enhance U.S. security by protecting U.S. retaliatory forces; by interdicting "limited" nuclear strikes; by further confusing Soviet predictions of the outcome of a strike; by driving Soviet missile deployments in directions favored by the United States; by lessening the consequences of nuclear attack; and/or by fulfilling still other strategic goals.

Critics dispute the validity of some of these goals; dispute that technology can fulfill the truly useful goals; and/or argue that the many harmful side effects of introducing BMD to the strategic equation and altering the Anti-Ballistic Missile (ABM) Treaty regime are not worth satisfying these goals.

To address the wisdom of less-than-perfect defense, the public and policymakers would need a precise statement of the strategic goal of the deployment, an assessment of whether technology could satisfy that goal, and an analysis balancing fulfillment of the goal against the side effects and uncertainties of introducing a new ingredient into the strategic nuclear arena.

3. **The strategic goal of President Reagan's Strategic Defense Initiative calling for emphasized BMD research—perfect, near-perfect, or less-than-perfect defense against ballistic missiles—remains unclear.** No explicit technical standards or criteria are therefore available against which to measure the technological prospects and progress of this initiative.

4. **In all cases, directed-energy weapons and other devices with the specifications needed for boost-phase intercept of ICBMs have not yet been built in the laboratory, much less in a form suitable for incorporation in a complete defense system.** These devices include chemical lasers, excimer and free electron lasers, x-ray lasers, particle beams, lightweight high-velocity kinetic energy weapons, and microwave generators, together with tracking, aiming, and pointing mechanisms, power sources, and other essential accompaniments.

It is unknown whether or when devices with the required specifications can be built.

5. **Moreover, making the technological devices perform to the needed specifications in a controlled situation is not the crux of the technical challenge facing designers of an effective ballistic missile defense. A distinct challenge is to fashion from these devices a reliable defensive architecture, taking into account vulnerability**

of the defense components, susceptibility to future Soviet countermeasures, and cost relative to those countermeasures.

New intercept mechanisms—directed energy weapons and the like—therefore do not by themselves necessarily herald dramatically new BMD capabilities.

6. **It is clear that potent directed-energy weapons will be developed for other military purposes, even if such weapons are never incorporated into effective BMDs.** Such weapons might have a role in nuclear offense as well as defense, in anti-satellite (ASAT) attack, in anti-aircraft attack, and in other applications of concern to nuclear policy and arms control. Defense and arms control policy will thus need to face the advent of these new weapons, irrespective of their BMD dimension.

7. **For modest defensive goals requiring less-than-perfect performance, traditional reentry phase defenses and/or more advanced mid-course defenses might suffice.** Such defenses present less technical risk than systems that incorporate a boost-phase layer, and they could probably be deployed more quickly.

New ideas for improving such "old" BMD concepts have emerged in the atmosphere of technical optimism enjoyed by the boost-phase concepts.

8. **Deployment of missile defenses based on new technologies is forbidden by the Anti-Ballistic Missile (ABM) Treaty reached at SALT I.** The Treaty permits only restricted deployment of traditional BMDs using fixed, ground-based radars and interceptor missiles. Research into new technologies, and in selected cases development and testing of defense systems based on these technologies, are allowed within the Treaty.

9. **There is a close connection, not explored in detail in this Background Paper, between advanced BMD concepts and future anti-satellite (ASAT) systems.** This connection springs from four observations: 1) ASAT attack on space-based weapons and sensors is probably the most attractive countermeasure to boost-phase BMD; 2) directed-energy weapons are more likely to succeed in the easier mission of ASAT than in the more difficult mission of boost-phase BMD; 3) to a degree dependent on technical details, early stages of development of boost phase BMDs might be conducted in the guise of ASAT development, stimulating anxieties about the health of the ABM Treaty regime; 4) to a degree dependent on technical details, concluding a treaty with the Soviet Union limiting ASAT development would impede BMD research at an earlier stage than would occur under the terms of the ABM Treaty alone.

APPENDIX A: THE CONCLUSION OF PRESIDENT REAGAN'S MARCH 23, 1983, SPEECH ON DEFENSE SPENDING AND DEFENSIVE TECHNOLOGY

Weekly Compilation of

Presidential Documents

Monday, March 28, 1983
Volume 19—Number 12
Pages 423–466

Now, thus far tonight I've shared with you my thoughts on the problems of national security we must face together. My predecessors in the Oval Office have appeared before you on other occasions to describe the threat posed by Soviet power and have proposed steps to address that threat. But since the advent of nuclear weapons, those steps have been increasingly directed toward deterrence of aggression through the promise of retaliation.

This approach to stability through offensive threat has worked. We and our allies have succeeded in preventing nuclear war for more than three decades. In recent months, however, my advisers, including in particular the Joint Chiefs of Staff, have underscored the necessity to break out of a future that relies solely on offensive retaliation for our security.

Over the course of these discussions, I've become more and more deeply convinced that the human spirit must be capable of rising above dealing with other nations and human beings by threatening their existence. Feeling this way, I believe we must thoroughly examine every opportunity for reducing tensions and for introducing greater stability into the strategic calculus on both sides.

One of the most important contributions we can make is, of course, to lower the level of all arms, and particularly nuclear arms. We're engaged right now in several negotiations with the Soviet Union to bring about a mutual reduction of weapons. I will report to you a week from tomorrow my thoughts on that score. But let me just say, I'm totally committed to this course.

If the Soviet Union will join with us in our effort to achieve major arms reduction, we will have succeeded in stabilizing the nuclear balance. Nevertheless, it will still be necessary to rely on the specter of retaliation, on mutual threat. And that's a sad commentary on the human condition. Wouldn't it be better to save lives than to avenge them? Are we not capable of demonstrating our peaceful intentions by applying all our abilities and our ingenuity to achieving a truly lasting stability? I think we are. Indeed, we must.

After careful consultation with my advisers, including the Joint Chiefs of Staff, I believe there is a way. Let me share with you a vision of the future which offers hope. It is that we embark on a program to counter the awesome Soviet missile threat with measures that are defensive. Let us turn to the very strengths in technology that spawned our great industrial base and that have given us the quality of life we enjoy today.

What if free people could live secure in the knowledge that their security did not rest upon the threat of instant U.S. retaliation to deter a Soviet attack, that we could intercept and destroy strategic ballistic missiles before they reached our own soil or that of our allies?

I know this is a formidable, technical task, one that may not be accomplished before the end of this century. Yet, current technology has attained a level of sophistication where it's reasonable for us to begin this effort. It will take years, probably decades of effort on many fronts. There will be failures and setbacks, just as there will be successes and breakthroughs. And as we proceed, we must remain constant in preserving the nuclear deterrent and maintaining a solid capability for flexible response. But isn't it worth every investment necessary to free the world from the threat of nuclear war? We know it is.

In the meantime, we will continue to pursue real reductions in nuclear arms, negotiating from a position of strength that can be ensured only by modernizing our strategic forces. At the same time, we must take steps to reduce the risk of a conventional military conflict escalating to nuclear war by improving our non-nuclear capabilities.

America does possess—now—the technologies to attain very significant improvements in the effectiveness of our conventional, non-nuclear forces. Proceeding boldly with these new technologies, we can significantly reduce any incentive that the Soviet Union may have to threaten attack against the United States or its allies.

As we pursue our goal of defensive technologies, we recognize that our allies rely upon our strategic offensive power to deter attacks against them. Their vital interests and ours are inextricably linked. Their safety and ours are one. And no change in technology can or will alter that reality. We must and shall continue to honor our commitments.

I clearly recognize that defensive systems have limitations and raise certain problems and ambiguities. If paired with offensive systems, they can be viewed as fostering an aggressive policy, and no one wants that. But with these considerations firmly in mind, I call upon the scientific community in our country, those who gave us nuclear weapons, to turn their great talents now to the cause of mankind and world peace, to give us the means of rendering these nuclear weapons impotent and obsolete.

Tonight, consistent with our obligations of the ABM treaty and recognizing the need for closer consultation with our allies, I'm taking an important first step. I am directing a comprehensive and intensive effort to define a long-term research and development program to begin to achieve our ultimate goal of eliminating the threat posed by strategic nuclear missiles. This could pave the way for arms control measures to eliminate the weapons themselves. We seek neither military superiority nor political advantage. Our only purpose—one all people share—is to search for ways to reduce the danger of nuclear war.

My fellow Americans, tonight we're launching an effort which holds the promise of changing the course of human history. There will be risks, and results take time. But I believe we can do it. As we cross this threshold, I ask for your prayers and your support.

Thank you, good night, and God bless you.

Note: The President spoke at 8:02 p.m. from the Oval Office at the White House. The address was broadcast live on nationwide radio and television.

Following his remarks, the President met in the White House with a number of administration officials, including members of the Cabinet, the White House staff, and the Joint Chiefs of Staff, and former officials of past administrations to discuss the address.

WASHINGTON, D.C., 20451

Treaty Between the United States of America and the Union of Soviet Socialist Republics on the Limitation of Anti-Ballistic Missile Systems

Signed at Moscow May 26, 1972
Ratification advised by U.S. Senate August 3, 1972
Ratified by U.S. President September 30, 1972
Proclaimed by U.S. President October 3, 1972
Instruments of ratification exchanged October 3, 1972
Entered into force October 3, 1972

The United States of America and the Union of Soviet Socialist Republics, hereinafter referred to as the Parties,

Proceeding from the premise that nuclear war would have devastating consequences for all mankind,

Considering that effective measures to limit anti-ballistic missile systems would be a substantial factor in curbing the race in strategic offensive arms and would lead to a decrease in the risk of outbreak of war involving nuclear weapons,

Proceeding from the premise that the limitation of anti-ballistic missile systems, as well as certain agreed measures with respect to the limitation of strategic offensive arms, would contribute to the creation of more favorable conditions for further negotiations on limiting strategic arms,

Mindful of their obligations under Article VI of the Treaty on the Non-Proliferation of Nuclear Weapons,

Declaring their intention to achieve at the earliest possible date the cessation of the nuclear arms race and to take effective measures toward reductions in strategic arms, nuclear disarmament, and general and complete disarmament,

Desiring to contribute to the relaxation of international tension and the strengthening of trust between States,

Have agreed as follows:

Article I

1. Each party undertakes to limit anti-ballistic missile (ABM) systems and to adopt other measures in accordance with the provisions of this Treaty.

2. Each Party undertakes not to deploy ABM systems for a defense of the territory of its country and not to provide a base for such a defense, and not to deploy ABM systems for defense of an individual region except as provided for in Article III of this Treaty.

Article II

1. For the purpose of this Treaty an ABM system is a system to counter strategic ballistic missiles or their elements in flight trajectory, currently consisting of:

(a) ABM interceptor missiles, which are interceptor missiles constructed and deployed for an ABM role, or of a type tested in an ABM mode;

(b) ABM launchers, which are launchers constructed and deployed for launching ABM interceptor missiles; and

(c) ABM radars, which are radars constructed and deployed for an ABM role, or of a type tested in an ABM mode.

2. The ABM system components listed in paragraph 1 of this Article include those which are:

(a) operational;
(b) under construction;
(c) undergoing testing;
(d) undergoing overhaul, repair or conversion; or
(e) mothballed.

Article III

Each Party undertakes not to deploy ABM systems or their components except that:

(a) within one ABM system deployment area having a radius of one hundred and fifty kilometers and centered on the Party's national capital, a Party may deploy: (1) no more than one hundred ABM launchers and no more than one hundred ABM interceptor missiles at launch sites, and (2) ABM radars within no more than six ABM radar complexes, the area of each complex being circular and having a diameter of no more than three kilometers; and

(b) within one ABM system deployment area having a radius of one hundred and fifty kilometers and containing ICBM silo launchers, a Party may deploy: (1) no more than one hundred ABM launchers and no more than one hundred ABM interceptor missiles at launch sites, (2) two large phased-array ABM radars comparable in potential to corresponding ABM radars operational or under construction on the date of signature of the Treaty in an ABM system deployment area containing ICBM silo launchers, and (3) no more than eighteen ABM radars each having a potential less than the potential of the smaller of the above-mentioned two large phased-array ABM radars.

Article IV

The limitations provided for in Article III shall not apply to ABM systems or their components used for development or testing, and located within current or additionally agreed test ranges. Each Party may have no more than a total of fifteen ABM launchers at test ranges.

Article V

1. Each Party undertakes not to develop, test, or deploy ABM systems or components which are sea-based, air-based, space-based, or mobile land-based.

2. Each Party undertakes not to develop, test, or deploy ABM launchers for launching more than one ABM interceptor missile at a time from each launcher, not to modify deployed launchers to provide them with such a capability, not to develop, test, or deploy automatic or semi-automatic or other similar systems for rapid reload of ABM launchers.

Article VI

To enhance assurance of the effectiveness of the limitations on ABM systems and their components provided by the Treaty, each Party undertakes:

(a) not to give missiles, launchers, or radars, other than ABM interceptor missiles, ABM launchers, or ABM radars, capabilities to counter strategic ballistic missiles or their elements in flight trajectory, and not to test them in an ABM mode; and

(b) not to deploy in the future radars for early warning of strategic ballistic missile attack except at locations along the periphery of its national territory and oriented outward.

Article VII

Subject to the provisions of this Treaty, modernization and replacement of ABM systems or their components may be carried out.

Article VIII

ABM systems or their components in excess of the numbers or outside the areas specified in this Treaty, as well as ABM systems or their components prohibited by this Treaty, shall be destroyed or dismantled under agreed procedures within the shortest possible agreed period of time.

Article IX

To assure the viability and effectiveness of this Treaty, each Party undertakes not to transfer to other States, and not to deploy outside its national territory, ABM systems or their components limited by this Treaty.

Article X

Each Party undertakes not to assume any international obligations which would conflict with this Treaty.

Article XI

The Parties undertake to continue active negotiations for limitations on strategic offensive arms.

Article XII

1. For the purpose of providing assurance of compliance with the provisions of this Treaty, each Party shall use national technical means of verification at its disposal in a manner consistent with generally recognized principles of international law.

2. Each Party undertakes not to interfere with the national technical means of verification of the other Party operating in accordance with paragraph 1 of this Article.

3. Each Party undertakes not to use deliberate concealment measures which impede verification by national technical means of compliance with the provisions of this Treaty. This obligation shall not require changes in current construction, assembly, conversion, or overhaul practices.

Article XIII

1. To promote the objectives and implementation of the provisions of this Treaty, the Parties shall establish promptly a Standing Consultative Commission, within the framework of which they will:

(a) consider questions concerning compliance with the obligations assumed and related situations which may be considered ambiguous;

(b) provide on a voluntary basis such information as either Party considers necessary to assure confidence in compliance with the obligations assumed;

(c) consider questions involving unintended interference with national technical means of verification;

(d) consider possible changes in the strategic situation which have a bearing on the provisions of this Treaty;

(e) agree upon procedures and dates for destruction or dismantling of ABM systems or their components in cases provided for by the provisions of this Treaty;

(f) consider, as appropriate, possible proposals for further increasing the viability of this Treaty, including proposals for amendments in accordance with the provisions of this Treaty;

(g) consider, as appropriate, proposals for further measures aimed at limiting strategic arms.

2. The Parties through consultation shall establish, and may amend as appropriate, Regulations for the Standing Consultative Commission governing procedures, composition and other relevant matters.

Article XIV

1. Each Party may propose amendments to this Treaty. Agreed amendments shall enter into force in accordance with the procedures governing the entry into force of this Treaty.

2. Five years after entry into force of this Treaty, and at five-year intervals thereafter, the Parties shall together conduct a review of this Treaty.

Article XV

1. This Treaty shall be of unlimited duration.

2. Each Party shall, in exercising its national sovereignty, have the right to withdraw from this Treaty if it decides that extraordinary events related to the subject matter of this Treaty have jeopardized its supreme interests. It shall give notice of its decision to the other Party six months prior to withdrawal from the Treaty. Such notice shall include a statement of the extraordinary events the notifying Party regards as having jeopardized its supreme interests.

Article XVI

1. This Treaty shall be subject to ratification in accordance with the constitutional procedures of each Party. The Treaty shall enter into force on the day of the exchange of instruments of ratification.

2. This Treaty shall be registered pursuant to Article 102 of the Charter of the United Nations.

DONE at Moscow on May 26, 1972, in two copies, each in the English and Russian languages, both texts being equally authentic.

FOR THE UNITED STATES OF AMERICA

President of the United States of America

FOR THE UNION OF SOVIET SOCIALIST REPUBLICS

General Secretary of the Central Committee of the CPSU

Agreed Statements, Common Understandings, and Unilateral Statements Regarding the Treaty Between the United States of America and the Union of Soviet Socialist Republics on the Limitation of Anti-Ballistic Missiles

1. Agreed Statements

The document set forth below was agreed upon and initialed by the Heads of the Delegations on May 26, 1972 (letter designations added):

AGREED STATEMENTS REGARDING THE TREATY BETWEEN THE UNITED STATES OF AMERICA AND THE UNION OF SOVIET SOCIALIST REPUBLICS ON THE LIMITATION OF ANTI-BALLISTIC MISSILE SYTEMS

[A]

The Parties understand that, in addition to the ABM radars which may be deployed in accordance with subparagraph (a) of Article III of the Treaty, those non-phased-array ABM radars operational on the date of signature of the Treaty within the ABM system deployment area for defense of the national capital may be retained.

[B]

The Parties understand that the potential (the product of mean emitted power in watts and antenna area in square meters) of the smaller of the two large phased-array ABM radars referred to in subparagraph (b) of Article III of the Treaty is considered for purposes of the Treaty to be three million.

[C]

The Parties understand that the center of the ABM system deployment area centered on the national capital and the center of the ABM system deployment area containing ICBM silo launchers for each Party shall be separated by no less than thirteen hundred kilometers.

[D]

In order to insure fulfillment of the obligation not to deploy ABM systems and their components except as provided in Article III of the Treaty, the Parties agree that in the event ABM systems based on other physical principles and including components capable of substituting for ABM interceptor missiles, ABM launchers, or ABM radars are created in the future, specific limitations on such systems and their components would be subject to discussion in accordance with Article XIII and agreement in accordance with Article XIV of the Treaty.

[E]

The Parties understand that Article V of the Treaty includes obligations not to develop, test or deploy ABM interceptor missiles for the delivery by each ABM interceptor missile of more than one independently guided warhead.

[F]

The Parties agree not to deploy phased-array radars having a potential (the product of mean emitted power in watts and antenna area in square meters) exceeding three million, except as provided for in Articles III, IV and VI of the Treaty, or except for the purposes of tracking objects in outer space or for use as national technical means of verification.

[G]

The Parties understand that Article IX of the Treaty includes the obligation of the US and the USSR not to provide to other States technical descriptions or blue prints specially worked out for the construction of ABM systems and their components limited by the Treaty.

2. Common Understandings

Common understanding of the Parties on the following matters was reached during the negotiations:

A. Location of ICBM Defenses

The U.S. Delegation made the following statement on May 26, 1972:

Article III of the ABM Treaty provides for each side one ABM system deployment area centered on its national capital and one ABM system deployment area containing ICBM silo launchers. The two sides have registered agreement on the following statement: "The Parties understand that the center of the ABM system deployment area centered on the national capital and the center of the ABM system deployment area containing ICBM silo launchers for each Party shall be separated by no less than thirteen hundred kilometers." In this connection, the U.S. side notes that its ABM system deployment area for defense of ICBM silo launchers, located west of the Mississippi River, will be centered in the Grand Forks ICBM silo launcher deployment area. (See Agreed Statement [C].)

B. ABM Test Ranges

The U.S. Delegation made the following statement on April 26, 1972:

Article IV of the ABM Treaty provides that "the limitations provided for in Article III shall not apply to ABM systems or their components used for development or testing, and located within current or additionally agreed test ranges." We believe it would be useful to assure that there is no misunderstanding as to current ABM test ranges. It is our understanding that ABM test ranges encompass the area within which ABM components are located for test purposes. The current U.S. ABM test ranges are at White Sands, New Mexico, and at Kwajalein Atoll, and the current Soviet ABM test range is near Sary Shagan in Kazakhstan. We consider that non-phased array radars of types used for range safety or instrumentation purposes may be located outside of ABM test ranges. We interpret the reference in Article IV to "additionally agreed test

ranges" to mean that ABM components will not be located at any other test ranges without prior agreement between our Governments that there will be such additional ABM test ranges.

On May 5, 1972, the Soviet Delegation stated that there was a common understanding on what ABM test ranges were, that the use of the types of non-ABM radars for range safety or instrumentation was not limited under the Treaty, that the reference in Article IV to "additionally agreed" test ranges was sufficiently clear, and that national means permitted identifying current test ranges.

C. Mobile ABM Systems

On January 29, 1972, the U.S. Delegation made the following statement:

Article V(1) of the Joint Draft Text of the ABM Treaty includes an undertaking not to develop, test, or deploy mobile land-based ABM systems and their components. On May 5, 1971, the U.S. side indicated that, in its view, a prohibition on deployment of mobile ABM systems and components would rule out the deployment of ABM launchers and radars which were not permanent fixed types. At that time, we asked for the Soviet view of this interpretation. Does the Soviet side agree with the U.S. side's interpretation put forward on May 5, 1971?

On April 13, 1972, the Soviet Delegation said there is a general common understanding on this matter.

D. Standing Consultative Commission

Ambassador Smith made the following statement on May 22, 1972:

The United States proposes that the sides agree that, with regard to initial implementation of the ABM Treaty's Article XIII on the Standing Consultative Commission (SCC) and of the consultation Articles to the Interim Agreement on offensive arms and the Accidents Agreement,[1] agreement establishing the SCC will be worked out early in the follow-on SALT negotiations; until that is completed, the following arrangements will prevail: when SALT is in session, any consultation desired by either side under these Articles can be carried out by the two SALT Delegations; when SALT is not in session, *ad hoc* arrangements for any desired consultations under these Articles may be made through diplomatic channels.

Minister Semenov replied that, on an *ad referendum* basis, he could agree that the U.S. statement corresponded to the Soviet understanding.

E. Standstill

On May 6, 1972, Minister Semenov made the following statement:

In an effort to accommodate the wishes of the U.S. side, the Soviet Delegation is prepared to proceed on the basis that the two sides will in fact observe the obligations of both the Interim Agreement and the ABM Treaty beginning from the date of signature of these two documents.

In reply, the U.S. Delegation made the following statement on May 20, 1972:

---

[1]See Article 7 of Agreement to Reduce the Risk of Outbreak of Nuclear War Between the United States of America and the Union of Soviet Socialist Republics, signed Sept. 30, 1971.

The U.S. agrees in principle with the Soviet statement made on May 6 concerning observance of obligations beginning from date of signature but we would like to make clear our understanding that this means that, pending ratification and acceptance, neither side would take any action prohibited by the agreements after they had entered into force. This understanding would continue to apply in the absence of notification by either signatory of its intention not to proceed with ratification or approval.

The Soviet Delegation indicated agreement with the U.S. statement.

3. Unilateral Statements

The following noteworthy unilateral statements were made during the negotiations by the United States Delegation:

A. Withdrawal from the ABM Treaty

On May 9, 1972, Ambassador Smith made the following statement:

The U.S. Delegation has stressed the importance the U.S. Government attaches to achieving agreement on more complete limitations on strategic offensive arms, following agreement on an ABM Treaty and on an Interim Agreement on certain measures with respect to the limitation of strategic offensive arms. The U.S. Delegation believes that an objective of the follow-on negotiations should be to constrain and reduce on a long-term basis threats to the survivability of our respective strategic retaliatory forces. The USSR Delegation has also indicated that the objectives of SALT would remain unfulfilled without the achievement of an agreement providing for more complete limitations on strategic offensive arms. Both sides recognize that the initial agreements would be steps toward the achievement of more complete limitations on strategic arms. If an agreement providing for more complete strategic offensive arms limitations were not achieved within five years, U.S. supreme interests could be jeopardized. Should that occur, it would constitute a basis for withdrawal from the ABM Treaty. The U.S. does not wish to see such a situation occur, nor do we believe that the USSR does. It is because we wish to prevent such a situation that we emphasize the importance the U.S. Government attaches to achievement of more complete limitations on strategic offensive arms. The U.S. Executive will inform the Congress, in connection with Congressional consideration of the ABM Treaty and the Interim Agreement, of this statement of the U.S. position.

B. Tested in ABM Mode

On April 7, 1972, the U.S. Delegation made the following statement:

Article II of the Joint Text Draft uses the term "tested in an ABM mode," in defining ABM components, and Article VI includes certain obligations concerning such testing. We believe that the sides should have a common understanding of this phrase. First, we would note that the testing provisions of the ABM Treaty are intended to apply to testing which occurs after the date of signature of the Treaty, and not to any testing which may have occurred in the past. Next, we would amplify the remarks we have made on this subject during the previous Helsinki phase by setting forth the objectives which govern the U.S. view on the subject, namely, while prohibiting testing of non-ABM components for ABM purposes: not to prevent testing of ABM components, and not to prevent testing of non-ABM components for

non-ABM purposes. To clarify our interpretation of "tested in an ABM mode," we note that we would consider a launcher, missile or radar to be "tested in an ABM mode" if, for example, any of the following events occur: (1) a launcher is used to launch an ABM interceptor missile, (2) an interceptor missile is flight tested against a target vehicle which has a flight trajectory with characteristics of a strategic ballistic missile flight trajectory, or is flight tested in conjunction with the test of an ABM interceptor missile or an ABM radar at the same test range, or is flight tested to an altitude inconsistent with interception of targets against which air defenses are deployed, (3) a radar makes measurements on a cooperative target vehicle of the kind referred to in item (2) above during the reentry portion of its trajectory or makes measurements in conjunction with the test of an ABM interceptor missile or an ABM radar at the same test range. Radars used for purposes such as range safety or instrumentation would be exempt from application of these criteria.

C. No-Transfer Article of ABM Treaty

On April 18, 1972, the U.S. Delegation made the following statement:

In regard to this Article [IX], I have a brief and I believe self-explanatory statement to make. The U.S. side wishes to make clear that the provisions of this Article do not set a precedent for whatever provision may be considered for a Treaty on Limiting Strategic Offensive Arms. The question of transfer of strategic offensive arms is a far more complex issue, which may require a different solution.

D. No Increase in Defense of Early Warning Radars

On July 28, 1970, the U.S. Delegation made the following statement:

Since Hen House radars [Soviet ballistic missile early warning radars] can detect and track ballistic missile warheads at great distances, they have a significant ABM potential. Accordingly, the U.S. would regard any increase in the defenses of such radars by surface-to-air missiles as inconsistent with an agreement.

APPENDIX C: OTHER APPLICATIONS OF DIRECTED ENERGY WEAPONS

This Background Paper treats only one—and probably one of the most difficult—military application of directed energy. Many other applications of widely varying plausibility vie for funding and attention. An assessment of all these schemes is well beyond the scope of this Paper, but the list below is provided for reference. Mention of a scheme does not imply that it has any technical or military promise; this question would have to be properly studied.

Anti-satellite (ASAT). Directed energy attack on satellites from space-, air-, or ground-based weapons is substantially easier than boost phase BMD. A satellite's orbit is completely predictable, making it in effect a fixed target. Long dwell times and low fluences suffice for ASAT attack on unshielded satellites. For instance, long illumination at just a few watts/cm² (several times the sun's normal irradiance in space) could upset the thermal control systems that allow spacecraft to endure the extremes of heat and cold in outer space. Substantial hardening of large and complex satellites (including sensors) to directed energy weapons from all directions at all times is impractical. Unlike BMD, which must handle thousands of boosters in a few minutes, ASATs would have fewer targets and longer attack times. Last, BMDs must operate under the most hostile circumstances imaginable, whereas the superpowers might use ASATs in scenarios short of nuclear war.

This Background Paper has stressed (see Section 5.1) that maturation of the same technologies involved in boost phase BMD virtually assures potent ASATs. The so-called "Star Wars" systems could well be their own worst threats. Besides the intrinsic ease of ASAT over BMD, a Soviet defense suppression ASAT attack on U.S. defensive battle stations would have three key factors working in its favor: 1) The Soviets would pick the time and sequence of attack on the U.S. BMD system and launch of their ICBMs; 2) The Soviets need not destroy the entire defensive constellation, but only "punch a hole" for their ICBMs to pass through; 3) The attack would take place over Soviet territory.

Ground-based laser ASATs, presumably using excimer or free-electron lasers for best atmospheric propagation, would have the advantages of large size and power supplies. Airborne lasers could avoid some of the propagation disturbances introduced by denser air at low altitudes, but turbulence around the airplane skin could require adaptive beam compensation.

Space-based directed energy ASATs are the most interesting category of all, since they would be, in effect, long-range space mines. Rather than positioning itself next to its quarry like an ordinary space mine, a laser could be thousands of kilometers away and still be able to strike within milliseconds upon receipt of a radio signal from the gound.

Strategic offense. If they mature, the directed energy devices discussed for BMD might turn out to have been better termed "offensive breakthroughs" than "defensive breakthroughs." Consider, for example, a fleet of Soviet x-ray lasers launched simultaneously with (or minutes before) a Soviet first-stike ICBM attack. The pop-up x-ray lasers' job would be to intercept any U.S. ICBMs launched before arrival of Soviet silo-killing RVs. The Soviet x-ray lasers would therefore deprive the U.S. of its option for launch under attack. Microwave generators might be used for EMP-like attack on the U.S. command and control system. Another example of offensive use of beam weapons would be Soviet ASAT attack on U.S. warning, communications, nuclear detonation detection, or navigation satellites important to the U.S. rataliatory capability. Yet another example would of course be suppression of any U.S. BMD that used space-based weapons or sensors.

Bus intercept. This Background Paper has focused on intercept of ICBMs before booster burnout. Intercept of the bus or post boost vehicle poses a rather different challenge. Post-boost phase for today's ICBMs is rather long (several minutes) but could be shortened drastically on future ICBMs. Bus tracking requires a different sensor than booster tracking, since the bus plume

is much less conspicuous, and the bus rocket motor may not operate continuously. The bus is a target of declining value as it dispenses its RVs. Interruption of bus operation would not prevent the bus and its contents from continuing their ballistic flight to the target country, though the aim might be very wide of the target. Operating above the atmosphere, the bus can deploy lightweight shields, decoys, and sensor countermeasures (e.g., corner reflectors). On the other hand, x-ray lasers and neutral particle beams that cannot penetrate the atmosphere can attack the bus in space.

Anti-SLBM. A number of schemes have been suggested for using directed energy weapons against SLBMs, besides the obvious extensions of ICBM defense. Thus pop-up x-ray lasers could be positioned on U.S. coasts or ships at sea to intercept SLBMs launched from nearby Soviet submarines. Aircraft patrolling coastal waters and carrying lasers could attack ascending SLBMs in their area.

Anti-IRBM. Intermediate range ballistic missiles (IRBMs) have short boost phases and potentially low trajectories, making anti-IRBM defense rather different from anti-ICBM defense and perhaps better accomplished with ground-based terminal BMD systems deployed in the theater.

Defense of satellites (DSAT). Low-power wide-divergence (small optics) laser satellites (perhaps HF for high specific energy) could serve as "escorts" for other satellites, defending the other satellites from hostile objects—mines, ASAT missiles —approaching within a given range.

Anti-aircraft. At least four schemes have been broached for using directed energy weapons against aircraft or cruise missiles. The most ambitious would involve a worldwide constellation of trackers (possibly LWIR) and beam weapons (possibly DF or short wavelength lasers) to attack Soviet Blackjack strategic bombers, Backfire bombers attacking U.S. aircraft carriers, Soviet airborne command post "Doomsday planes," Soviet AWACS radar planes, and so on. In a second scheme, B-1 or B-52 bombers would be outfitted with lasers (possibly DF) to protect them from Soviet fighters, surface-to-air missiles (SAMs), and air-to-air missiles. A third scheme equips carrier battle groups with lasers or particle beams to defend themselves against cruise missile attack. Fourth and last, ground-based beam weapons might replace surface-to-air missiles for local air defense.

Midcourse and terminal BMD. Intense electron beams have long been studied as replacements for interceptors in reentry BMD. In midcourse BMD, beam weapons might not only destroy RVs, but aid discrimination of RVs from lightweight decoys: lasers, particle beams, or x-ray lasers would illuminate approaching objects, and sensors would use the response of each object as an extra piece of data to judge whether it was a true RV (see Section 6).

Submarine communications. This scheme would use a blue-green laser to communicate with submerged submarines. Seawater is opaque to all but VLF and ELF radio frequencies, used for submarine communications today, and to the blue-green portion of the visible light spectrum. A blue-green laser beam originating on a satellite, reflected from a space-based mirror, or carried by an airplane would be modulated in accordance with the message to be transmitted and directed at a given spot on the ocean. After transmission of the full message, the beam would dwell on a neighboring spot and transmit again, and so on, eventually covering all submarine patrol areas. Optical sensors on the submarine hull would detect the message.

Blinding sensors and seekers. Analysts have studied a wide range of tactical applications for lasers, involving blinding of battlefield sensors, missile seekers, and even human beings.

Office of Technology Assessment

The Office of Technology Assessment (OTA) was created in 1972 as an analytical arm of Congress. OTA's basic function is to help legislative policymakers anticipate and plan for the consequences of technological changes and to examine the many ways, expected and unexpected, in which technology affects people's lives. The assessment of technology calls for exploration of the physical, biological, economic, social, and political impacts that can result from applications of scientific knowledge. OTA provides Congress with independent and timely information about the potential effects—both beneficial and harmful—of technological applications.

Requests for studies are made by chairmen of standing committees of the House of Representatives or Senate; by the Technology Assessment Board, the governing body of OTA; or by the Director of OTA in consultation with the Board.

The Technology Assessment Board is composed of six members of the House, six members of the Senate, and the OTA Director, who is a nonvoting member.

OTA has studies under way in nine program areas: energy and materials; industry, technology, and employment; international security and commerce; biological applications; food and renewable resources; health; communication and information technologies; oceans and environment; and science, transportation, and innovation.

Summary

In late 1982 and early 1983, the Subcommittee on Arms Control, Oceans, International Operations, and Environment of the Senate Committee on Foreign Relations held hearings on space weapons and arms control. To explore these issues further in a discussion format not easily achieved in hearings, Sen. Larry Pressler, Chairman of the Subcommittee, asked OTA to conduct a workshop focusing on anti-satellite (ASAT) weapons as one aspect of space arms control. The workshop, held in Washington, D.C., on January 30 and 31, 1984, provided an opportunity for technical, diplomatic, military, and policy-analysis experts to interact, think out loud, and build upon each other's ideas.

The workshop was organized into six sessions, although issues involving anti-satellite weapons and arms control are not easily compartmentalized into distinct subject areas. Each session was introduced by a 10- or 15-minute informal oral presentation which set the stage for further discussion. This workshop proceedings volume is organized along the same divisions as the sessions, with some rearrangement.

The first session, an overview, reviewed technical aspects of anti-satellite systems and presented a candidate set of topics for discussion in later sessions. The second session covered pros and cons of ASAT arms control. Soviet attitudes and efforts regarding ASATs were the focus of the third session; U.S. attitudes and developments in ASATs and ASAT arms control were reviewed in the fourth. The effect of ASATs on the continued viability of the 1972 Anti-Ballistic Missile (ABM) Treaty, and vice versa, were covered in the fifth session. The last session centered on verification issues.

At Senator Pressler's request, OTA is publishing the workshop proceedings. OTA's agreement with the panelists was that the workshop report would discuss the viewpoints, ideas, and findings arrived at during the conference, but that particular statements or opinions would not be attributed to specific individuals. Therefore, the transcript has been paraphrased and rearranged to form this report. The proceedings have been circulated among the panelists, who were given the opportunity to suggest corrections and clarifications. They have not been reviewed by the Technology Assessment Board.

The workshop panelists were asked to raise and clarify issues, not to resolve them. No attempt was made to reach conclusions or develop consenses during the workshop sessions. However, OTA has noted and listed below several points where the panelists appeared to be in general agreement. These points are followed by a brief discussion of some of the fundamental bases for disagreement among the panelists. Following that is a list of some issues, raised during the course of the workshop, which were felt to merit further research and analysis.

POINTS OF GENERAL AGREEMENT

No arms control agreement can eliminate all anti-satellite capability. However, panelists differed in interpreting the significance of this residual ASAT capability which would be infeasible or impractical to ban. Some systems not designed to be ASATs (ICBMs, manned spacecraft, etc.) nevertheless have some ASAT potential, making some de facto residual ASAT capability inevitable. ASAT arms control supporters stressed that it would be minor compared to the capability of extensive ASAT or "space mine" efforts which could be undertaken in the absence of an arms control agreement, while some of the ASAT arms con-

trol opponents believed that the residual capability might nevertheless pose a significant threat to U.S. satellites.

ASAT arms control cannot eliminate the need to protect or supplement vital satellites with a variety of survivability measures. However, it can serve to lessen the measures required to protect space systems. Under any arms control accord, programs to ensure survivability of critical satellites or programs which supplement or replace their function will remain vital. The temptation to assume that survivability measures could be relaxed following an agreement must be resisted. "We could be that stupid," said one panelist, "but we don't really have to be."

The "verifiability" of an ASAT accord can only be assessed for a specified set of restrictions and measures, and any discussion of the verifiability of a particular provision ought to include consideration of the significance of potential violations of that provision. The panelists did not evaluate in detail, partly because of security classification restrictions, the verifiability of compliance with the various kinds of arms control agreements that were discussed. It was clear that the standards of verification required for effective ASAT arms control are highly controversial. Panelists agreed, however, that bans on testing would require less extensive verification measures than bans on possession, and that compliance with some ASAT arms control provisions could be verified with high confidence.

Future U.S. and U.S.S.R. activities in space hold great potential for generating uncertainty and misunderstanding regarding the countries' respective intentions. Workshop participants agreed that the Soviet Union will continue its vigorous exploitation of space, and that some Soviet activities will be perceived in the United States as provocative. Similarly, some American actions will appear provocative to the Soviets. Both countries will observe activities which they will not completely understand and which will cause considerable concern. Misunderstandings concerning the intent of various space actions could be particularly dangerous during crises or low-level conflicts.

Ambiguities might be lessened or resolved with some type of "rules of the road" or "behavior in space" agreement. Some panelists thought that an agreement concerning behavior in space, or towards space objects, might serve to reduce tensions and uncertainties. Such an agreement need not be associated with other measures limiting anti-satellite weapons systems; indeed, there might be value even if (thought some panelists) or especially if (thought others) there were no accompanying ASAT restrictions. Such an agreement might be modeled after the "rules of the road" on the high seas, which are embodied in several international agreements that recognize freedom to operate, lessen the risk of accidental collision, and minimize unnecessary provocation at sea. Possibly the most valuable feature of a "rules of the road in space" agreement would be the establishment of a forum like the U.S.-U.S.S.R. Standing Consultative Commission, which would help maintain an ongoing dialog between the United States and the Soviet Union and would permit discussion of activities whose significance was not clear. A "rules of the road" agreement should not be allowed to impede more serious provisions concerning space weapons if such provisions are found to be desirable. The precise form of a "space behavior" agreement was not explored in depth at the workshop, and the political and diplomatic procedures and tradeoffs required to negotiate and implement such an agreement were not addressed.

If ASAT threats are reduced by an agreement, there may be fewer reservations about placing important systems in space, creating in turn greater incentive for developing ASAT weapons. If an accord has the effect of relaxing survivability measures at the same time that reliance on space systems is increasing, then the growth of targets both valuable and vulnerable might provide strong motivation to attempt covert ASAT development. This possible paradox reinforced panelists' observations that an ASAT accord is no substitute for effective measures to reduce space system vulnerability.

Preservation of the functions now performed in space does not require the survival of all space

assets. Military support activities carried out in space are very important, but they can be duplicated or distributed among many space systems. Furthermore, many alternatives to space-based systems exist or can be developed.

The idea that the United States needs an ASAT weapon in order to deter enemy ASAT attack was not strongly supported. Many participants felt that the ability to retaliate against terrestrial assets served to deter ASAT attack at least as well as the ability to respond in kind against enemy satellites. Furthermore, one of the rationales other than deterrence which has been given for the U.S. ASAT program—to carry out attacks on particularly hostile Soviet satellites—conflicts with the ASAT's deterrent role. Nobody at the workshop felt that ASAT attack scenarios were well enough understood to predict the outcome of "tit-for-tat" ASAT retaliatory attacks in general. The likelihood and nature of subsequent escalation would be highly dependent on which satellites were attacked and under what circumstances.

The U.S. air-launched ASAT weapon now undergoing testing is clearly technically superior to the present generation of Soviet ground-launched ASATs. The ability to home in from a wide range of directions, and the flexibility of being launched from highly mobile aircraft, will make the U.S. ASAT a considerably more capable weapon if deployed. The United States will be able to launch consecutive ASATs much more rapidly than the Soviets, who are restricted in how rapidly their ASAT can be fired by their limited number of launch sites and by the time required to recycle them. There are also significant asymmetries in the target sets which are at risk to the two systems. Many important space functions are carried out by the United States using satellites in geosynchronous orbit, well out of range of the Soviet ASAT. Many Soviet satellites with similar functions use highly elliptical "Molniya" orbits, which could be vulnerable to U.S. attack at their lower altitudes. However, the United States would face severe logistical and operational difficulties in attempting to exploit this vulnerability. In addition, since Soviet satellites are shorter lived than U.S. satellites and are consequently replaced more frequently, the Soviets may be better prepared to reconstitute space systems than the United States would be.

In spite of asymmetries in capability, neither the existing Soviet ASAT nor the U.S. ASAT undergoing tests poses a severe military threat to the other side. The present level of ASAT technology is significantly limited. Both U.S. and U.S.S.R. weapons are restricted to targets in low Earth orbit and cannot reach geosynchronous orbit. Both systems may have to wait several hours for a target satellite to come within range of the appropriate F-15 base (for the U.S. system) or ground launch site (for the Soviets), although the mobility of the F-15 makes this restriction considerably less severe for the U.S. ASAT. If either the U.S. or the U.S.S.R. system were mated to boosters able to reach geosynchronous orbit, the ascent would take many hours. In light of these limitations, many treaty proponents would tolerate (although not necessarily prefer) a treaty which would "grandfather" existing systems. Perceptions differed as to the relative political implications of the existing U.S.S.R. system versus the U.S. ASAT which is undergoing testing, but nobody felt that the overall military balance was affected significantly by either—especially when compared with potential future ASAT developments.

A ban on testing ASAT weapons would greatly increase the difficulty of developing a high-confidence, high-quality, dedicated ASAT system. Panelists thought it would be very difficult to develop and field a highly capable new system with no detectable tests. Some tests might go undetected—for example, there are many perfectly legitimate activities involving rendezvous in space which could be made to be partial tests of ASAT interception capability—but many tests would be required to instill confidence in an ASAT system, and some of these would probably be detected. Banning the tests would force the violator either to forgo tests or to test covertly; covert testing, assuming that it could in fact be carried out undetected, would certainly be more difficult

and less extensive than the overt testing that would be possible in the absence of a ban. In the absence of tests, all agreed that no one could be highly confident that a new system would be effective in difficult scenarios (against many targets in a short time interval and/or effective at geosynchronous altitude). If a system were to be developed without testing, the inability to make refinements based on tests and the lack of confidence developed through tests would degrade the system's military significance.

ASAT and ballistic missile defense (BMD) systems and technologies are closely related. As effective ASAT weapons are developed and introduced, boost-phase ballistic missile defense systems will become increasingly problematical since all such systems utilize space-based early warning systems and possibly other subsystems which would be vulnerable to ASAT attack. Many, although not all, prospective midcourse BMD systems would also have vulnerable space-based assets, and even terminal BMD systems would likely utilize space-based early-warning sensors. At the same time, even a poor quality or prototype midcourse or boost-phase BMD system may have very significant ASAT capability since satellites are much easier to destroy than missile warheads. Therefore, development of boost-phase and mid-course BMD systems will severely constrain ASAT arms control possibilities. Conversely, since ASAT and BMD technologies are related, treaties limiting ASAT development or testing will limit development and deployment of boost-phase and midcourse BMD systems. Of course, the 1972 ABM Treaty and 1974 protocol thereto already severely constrain testing, development, and deployment of BMD systems.

POINTS OF DISAGREEMENT

Disagreement over the desirability of an ASAT treaty hinges on basic philosophical differences over the role of arms control. Although acknowledged at the workshop, these differences were not discussed or debated significantly during the sessions. They are outlined below in an attempt to summarize some of the considerations most relevant to different sides of the ASAT arms control debate.

One attitude, supporting ASAT arms control, is that we value the safety of our own satellites more than we value the ability to destroy Soviet satellites. We want to protect those of our own military support functions which we presently carry out via satellites, and protecting them is much easier if our satellites are not threatened by a highly developed, highly capable Soviet ASAT. Preventing the Soviets from deploying an effective ASAT would be much more helpful than developing our own.

While a ban on all Soviet ASATs would be ideal, the principal U.S. interest is to prevent the Soviets from developing a highly capable system: one which works reliably, threatens satellites in geosynchronous orbit, operates with no warning, and/or attacks many targets at once. Several approaches, including banning ASAT testing, banning the development of new ASAT systems, or banning all dedicated ASAT systems, could inhibit such a Soviet development. Banning only tests or new developments would be more easily verified than banning all dedicated ASATs; however, a total ban might nevertheless be a more effective approach to preventing development of a highly capable Soviet system. Although no agreement can eliminate all ASAT capability, supporters of ASAT arms control felt that an agreement could be devised which would make Soviet development of such a highly capable ASAT system very difficult, and that such an agreement could be adequately verified. The criterion for supporting an agreement would be improvement in the security of our space systems as compared to not having an agreement.

A contrasting approach considers military competition between the United States and U.S.S.R. to be inevitable, with arms control in many cases not being an effective or appropriate alternative to that competition. Accordingly, the relevant measure of national security would be relative advantage or disadvantage of the United States with respect to the U.S.S.R. Those holding this view consider it essential to deny the enemy the use of space during a conflict when such use provides a military advantage. In the case of ASAT arms control, even if U.S. satellites were to be safer with an ASAT limitation or test ban than without one (which would almost certainly be the case), a treaty might not be appropriate if it would benefit the Soviet Union more than it would the United States. Such asymmetrical advantage might arise under an ASAT accord for two reasons: First, a treaty would divert the military competition away from an arena (ASAT competition) where the United States would otherwise have been able to exploit its superior ability to develop highly sophisticated technologies. Second, the Soviets might cheat. Because of the asymmetric nature of Soviet and American societies, it is argued, the Soviet Union is much more likely than the United States to cheat on an agreement. For the same reason, Soviet attempts to cheat are more likely to be successful. Whether or not the kinds of violations which might go undetected would in themselves pose major threats to U.S. security, any covert violation would work to our military disadvantage and would have undesirable political and psychological consequences as well.

There is disagreement regarding how much significance can be attributed to residual or covert ASAT capability. The panelists agreed that a considerable testing program is required in order to have high confidence in an ASAT system. However, there are differences of opinion regarding how significant an incompletely or covertly tested system might be. A covert system might not engender high confidence, it might not be as reliable as a dedicated, overtly tested system, and it might be discovered, but it might nevertheless still be developed. There is disagreement not only about how remote this possibility is, but also about how this possibility affects the relative advantages of a treaty versus the risks.

ASAT arms control is also complicated by more general considerations regarding the military use of space. On the one hand, emplacing weapons in space or using weapons against targets in space can be seen as breaking a de facto political taboo which would be difficult to restore. Furthermore, introducing weapons into space might make the world a more dangerous place; this is now almost universally believed to be the case concerning introduction of multiple independently targetable reentry vehicles (MIRVs). On the other hand, any space arms control might be viewed as a political and psychological barrier inhibiting the much wider exploration and exploitation of space as a theater of military operation. A primary example of the wider possibilities of space is ballistic missile defense—while many would not be willing to limit ASAT weapons at the price of impeding investigations into the possibilities of BMD, others see those restrictions on BMD which would be included in an ASAT accord as reinforcing the ABM treaty in support of its original and continuing goals.

TOPICS FOR FURTHER RESEARCH

Among the more general subject areas suggested to the workshop for further research were possibilities for "rules of the road" agreements in space. As noted above, many participants believed that some measures to reduce uncertainty and ambiguity in space might be desirable. Although possible models were proposed, potential agreements were not discussed in detail. What sort of mechanisms (be they unilateral actions, treaties, or informal working ar-

rangements) could be established to permit mutual U.S. and U.S.S.R. use of space with a minimum of suspicion?

Are there ways of characterizing ASATs such that we can define and ban the most threatening or destabilizing types? Certain activities in space are clearly more threatening than others, just as certain activities are more visible than others. Is there a way that a "rules of the road" agreement could focus on the more dangerous rather than the more visible? What are the implications for verification and for stability?

No treaty of any kind can be perfectly verified. Several questions arise in handling ASAT treaty provisions which must therefore be verifiable only partially, or with less than 100 percent confidence. One problem involves how general or specific treaty provisions must be made. Treaty language intended to prevent some particularly threatening activity (e.g., testing ASAT interceptors at geosynchronous orbit) might be phrased in general terms (e.g., forbidding all ASAT tests) which would include less threatening activities that might be less verifiable (e.g., testing ASATs in low earth orbit where they might be masked as non-ASAT-related operations). What are the implications of having varying levels of confidence in verifying compliance with treaty provisions? Are activities which are not explicitly proscribed under a treaty necessarily condoned?

Another verification issue requiring further work involves cooperative verification procedures. Although existing rules regarding freedom of navigation and innocent passage on the high seas permit forces of one country to approach those of another, approaching a foreign satellite closely enough to examine it in space might nevertheless not be taken kindly in the absence of prior approval. If nuclear weapons are to be kept out of space with high confidence, then cooperative inspection procedures (either in space or on the ground) will likely be required. Can such procedures be arranged?

Opening Statement by Senator Larry Pressler

In the quarter-century since the launch of the first man-made satellites, the world has witnessed a quantum leap in the development of space-based and space-related technology. These developments have largely served peaceful purposes. We have learned to use satellite data in crop forecasting; space systems are today's key link for communications between nations; and by operating in space we may be able to solve our energy crisis and learn more about the universe in which we live. The military has also played a major role in space. To date, military space programs have enhanced global security and provided a principal method for arms control verification. No one can dispute that the military should sustain these efforts.

But as technology has improved our ability to operate in space, attention has turned towards using space as a new medium of warfare. We are no longer simply speaking of using space systems for reconnaissance, military communications, early warning and crisis management, but we are on the threshold of transforming space into the new field of battle.

Some would argue that this threshold has already been crossed. Indeed, for over 15 years the Soviet Union has operated an anti-satellite weapon. That weapon continues to be tested and its use against American satellites would seriously harm U.S. security.

In response to this deployment, the United States has developed and started to test a counter-ASAT. This American system will become operational in the latter half of this decade.

The ASAT problem is, however, only the forward edge of a potentially ominous trend in the military uses of space. The United States, and no doubt the Soviet Union, is starting a process that may lead to the deployment of beam-powered weapons capable of attacking a large number and a wide variety of targets in or flying through space, including ballistic missiles.

While I support the goals of removing the threat posed by nuclear weapons, it is far from clear that the move into space-based ballistic missile defenses will remove this threat. We must proceed with caution and engage in careful deliberation before beginning such an initiative. These futuristic weapons are certain to cost hundreds of billions of dollars. They may be ineffective and could complicate the task of providing for an effective national defense posture, while undermining strategic stability.

Given the potential costs and risks, I believe that the Congress must carefully consider both the strategic options and their arms control implications. For this reason, the Senate Foreign Relations Arms Control Subcommittee has held a series of hearings on the issue of arms control in space. Let me note that we began our deliberations long before ASAT and so-called "Star Wars" weapons received the serious attention given to them today. In consequence of these hearings, the Foreign Relations Committee favorably reported out S.J. Res. 129 which calls for a return to the negotiating table on ASATs, a moratorium of limited duration on ASAT space flight tests, and the inclusion of future space weapons technologies in these talks.

The hearings in the Arms Control Subcommittee provided Senators with a great deal of information in analyzing the implications of a space arms race and the arms control alternatives. But we continue to face many uncertainties and many questions remain unanswered. These issues must be quickly addressed if arms control is to be relevant to the problem. In addition, the Congress will soon have to decide whether to fund a multi-billion dollar research program on directed energy weapons. This workshop should allow us to continue the learning process begun in the Foreign Relations Committee.

I am, therefore, pleased that the Office of Technology Assessment has agreed to conduct

this workshop. Special thanks go to OTA Director Jack Gibbons and to workshop director Peter Sharfman for organizing this meeting. In addition, I want to thank this highly distinguished group of participants for coming to Washington to share their wisdom with us, particularly our workshop Chairman, McGeorge Bundy.

As I said, the Congress has a great deal to learn about space weapons and arms control. I am certain that this workshop will have an important role in our examination of these issues.

Overview

This workshop focused on anti-satellite weapons as an arena for arms control. Early in the first session, however, a panelist pointed out that such a focus in many ways creates an artificial distinction. Space holds a special "emotional allure." Much of the public debate concerning the militarization of space may result as much from that allure as from an informed judgement of the contribution of space activities to the military balance of power.

"Nuclear weapons and nuclear war remain the most important focus for arms control," a panelist pointed out. "ASAT arms control could reinforce nuclear arms control, but it could also divert attention from that central, overriding threat." At the same time, however, he and the remainder of the panel recognized that the appeal of space for military support operations is indeed high, and that the "allure of space" cannot be neglected in any discussion of ASAT arms control.

ORGANIZING DISCUSSION

Three ways of organizing discussion about ASATs were presented in the opening session. The first is to enumerate the various mechanisms of destroying satellites. There are essentially three distinct types: 1) direct interceptors, such as the current U.S. and Soviet ASAT weapons which home in on and then destroy target satellites; 2) "space mines," satellites which are stationed in orbit and later detonated to destroy nearby satellites; and 3) directed-energy weapons, which destroy satellites by delivering particle or radiation beams from a distance.

Other techniques such as concealment, spoofing, jamming, capturing control, and attacking ground stations, can disrupt the operation of a satellite. The difference between interfering with a satellite and permanently disabling it is significant, especially with respect to what is possible or desirable to regulate in a treaty. This distinction was made several times during the workshop.

A second method of organizing ASAT issues is to focus on the functions of potential target satellites and on the implications of subjecting these satellites to attack. So far, there are five primary roles for military support satellites—communications, surveillance and warning, navigation, meteorology, and geodetic survey. Different measures may be required to preserve each of these different functions in the presence of an ASAT threat.

A third organizational scheme is to enumerate anti-satellite attack scenarios and consider their effects on military capabilities and their prospects for escalation. Journal articles and press reports have discussed "just about every possible circumstance" involving anti-satellite activity, from tampering in peacetime to global nuclear war. Studying various possible scenarios has the advantage that, while ASAT technology can and will change, the scenarios for ASAT conflict may be more constant.

DISCUSSION FOCUSES

According to one panelist, the intersections or confluences of these three approaches—ASAT technologies, tempting or particularly threatening targets, and plausible circumstances—show the relevance of ASAT weapons and tactics to arms control. He singled out in the first workshop session several points about which further discussion could be fo-

cused. These issues, along with some items identified later in the workshop, are briefly described below and include:

RESIDUAL ASAT CAPABILITY

Many systems can destroy satellites besides those built or designed for that purpose. For example, ICBMs can be reprogrammed to attack satellites rather than terrestrial targets, giving both the U.S. and U.S.S.R. a de facto nuclear ASAT capability. The nuclear-armed Galosh anti-ballistic missile (ABM) interceptors, deployed by the Soviet Union around Moscow under the terms of the 1972 ABM Treaty, can easily destroy satellites passing overhead at altitudes lower than about 1,000 km. However, several panelists pointed out that the use of nuclear warheads against satellites is not plausible in situations short of nuclear war.

There is also nonnuclear residual capability. Rendezvous and docking procedures used in manned spaceflight could be applied to ASAT interception. With sufficient radar support, it is conceivable that Galosh interceptors having conventional warheads might be effective against satellites.

Since the above systems would remain even if all dedicated ASAT systems were banned, panelists agreed that residual ASAT capability will exist under any arms control regime. The more that space utilization and space technology develop, the greater the residual ASAT threat will become. Therefore, panelists strongly emphasized that no arms control agreement can replace the need to make the functions that we carry out in space survivable (see app. A). Functional survivability includes protection against non-ASAT threats, such as attacks on ground stations, and it does not require survival of all space assets. Space systems can be duplicated, and non-space-based alternatives for many support functions now done in space can be developed. Panelists noted that survivability would be easier to ensure if dedicated ASAT systems, especially highly threatening future ones, were controlled.

Determining the level and effectiveness of residual ASAT capability is important to weighing the desirability of any treaty. An ineffective ASAT which had no more capability than the residual capability of non-ASAT systems would not significantly increase the threat these non-ASAT systems potentially pose to satellites. There is, then, some minimum level of capability that an ASAT weapon would have to exceed before its existence would be significant. It would make little sense for an ASAT treaty to require a level of verification holding ASAT capability far below this minimum. However, exactly where this minimum level is located is a highly debatable point. Panelists who felt that the residual capability of non-ASAT systems was quite significant questioned the value of negotiating any limit to dedicated ASATs at all. The level of residual ASAT capability was discussed further in the verification session of the workshop.

COMPARISON OF U.S. AND U.S.S.R. ASAT WEAPONS

Although this topic is unavoidable in any discussion of ASATs, several panelists warned against overemphasizing the two countries' respective capabilities in isolation, without simultaneously considering their respective target sets and possible scenarios.

Both U.S. and U.S.S.R. weapons are designed to intercept target satellites using a three-step procedure. First, ground-based sensors identify the target satellite and determine its orbit. Next, the interceptor is launched and guided towards the intercept point, and finally, the interceptor's homing sensors are activated and it closes in on the target satellite. However, while the U.S. air-launched ASAT climbs directly towards its target satellite in ten or twenty minutes, the Soviet ground-launched ASAT must roughly match orbits with its target, a process which has taken up to several hours in tests.

The range of the booster and the homing process determine which target orbits an ASAT weapon can threaten. The U.S. Miniature Homing Vehicle (MHV) ASAT weapon now undergoing testing destroys its target by direct impact and can home in on its target from a wide range of directions. It needs only to get to the same place at the same time as its target, and does not need to match orbits with that target. The present generation of Soviet ASATs, on the other hand, is co-orbital—it needs to be in the same place at the same time traveling roughly in the same direction at the same speed as its target. So far, all Soviet ASAT tests have been conducted against targets in orbits with inclination angles near 65 degrees.

Workshop panelists felt it "beyond doubt" that the U.S. air-launched approach is "clearly superior" to the Soviet ground-launched technique. Besides the limitation of having to share its target's orbit, the Soviet ASAT is restricted by the small number of launch sites that can handle its modified SS-9 booster. As many as twelve hours might be required, while the Earth turns under the target orbit, to bring the target within range of a launch site. The Soviets are further limited by the recycle time of each launch pad, and they cannot launch many ASATs in rapid succession. U.S. air-launched ASAT interceptors can be launched much more rapidly, and from a much wider geographic area, than the Soviet ground-launched ASAT. The advantages of the U.S. ASAT's airplane-launched approach, and its direct homing interception, more than compensate for its altitude limit, which has not been released by the Air Force but was estimated by a panelist to be considerably lower than that of the Soviet ASAT. Although present U.S. plans call for ASAT-equipped F-15 squadrons having the associated logistical support to be based only at two sites within the continental United States, the planes and the associated support structure could be based in other areas to give even wider geographic coverage and more immediate response.

Another important asymmetry between near-term U.S. and U.S.S.R. ASAT capabilities is the target sets which each weapon will face. Many critical functions which the United States performs in space are carried out by satellites in geosynchronous orbit, far out of range of the Soviet ASAT. Similar functions for the U.S.S.R. are in many cases carried out by satellites in highly elliptical "Molniya" orbits, which could be vulnerable to U.S. attack at their lower altitudes. Present plans for deploying ASAT-equipped squadrons within the continental United States would not permit such attacks, but suitably equipped planes might be able to attack these Soviet satellites if they, and the appropriate logistical support, were based in the Southern Hemisphere. Even assuming appropriate bases could be obtained, in-flight refueling would be required.

Countering the potential advantages of the United States system is that it is still undergoing preliminary testing, whereas the Soviet ASAT has been tested, in a restricted manner, about twenty times over the last 16 years. The U.S. Department of Defense considers the Soviet ASAT to be operational. A panelist warned against comparing something that is "technologically possible that one side doesn't have" against an opposing system which "perhaps looks a little bit like a turkey" but in fact does have some capability. At any rate, no one doubted that the U.S. system could be made operational within a few years at most.

MILITARY ROLE IN SPACE

Much of the concern about ASATs and ASAT arms control deals with the role of satellites in military activities and the corresponding threat to military capability posed by ASAT weapons. Space systems are used extensively for military support, but satellites do not now fill a crucial, indispensable, and irreplaceable role. Many functions now carried out in space can be performed by other means. A paradox arises in that, to the extent that ASAT arms control masks the intrinsic vulnerability of satellites, alternatives to space systems may not seem necessary and satellites will be increasingly relied upon. If space utilization grows, so will the incentive to build

ASAT weapons. The solution is for arms control, if pursued, to supplement satellite survivability and redundancy programs and not to replace them. This point was repeated throughout the workshop: ASAT arms control cannot be a substitute for protecting and duplicating satellite functions.

ASAT ATTACK SCENARIOS AND POTENTIAL FOR ESCALATION

Does ASAT attack have a unique potential for triggering wider conflict? Does it imply that future conflict might be restricted to space? These points stimulated considerable discussion, but the panel doubted both.

Since military satellites are used principally for support activities, they don't functionally differ from terrestrial support systems. "Is the sinking of a U.S. intelligence ship not as likely and as inflammatory in a crisis as interception of a U.S. spy satellite?" questioned one panelist. Another panelist pointed out that "war in space cannot at all be separated from war on Earth." In any conflict, each side has certain objectives, and they are on the ground. "You don't shoot satellites just for the fun of it."

Other participants pointed out, though, that an ASAT attack might be less provocative than a terrestrial attack since people would not be directly threatened. "Maybe you destroy the 'allure of space'," said a panelist, "but you don't kill anybody." One panel member stressed that one cannot dismiss isolated ASAT scenarios to consider ASAT attack only in the context of a wider conflict. "I am skeptical about that because the United States has worked as hard as it possibly can to make itself extraordinarily vulnerable" to a low-level ASAT attack. "We have nothing in the pipeline to replace anything that's in space."

One panelist stated that the most worrisome ASAT scenarios involve low-level conflicts. In desperate cases, even a party not having a dedicated ASAT weapon might be tempted to attack an opposing satellite with whatever means could be arranged on the spur of the moment. In a low-level crisis which had not yet escalated to such a stage, however, existence or lack of a dedicated ASAT able to intercept with high confidence a threatening satellite might make the difference between attacking and not attacking. Carrying out such an attack "would be a tremendous temptation if it were easy to do so and could be done quickly and precisely and with very low collateral damage," even with the attendant risk of escalation.

Another panelist disagreed, maintaining that having fewer or poorer weapons does not necessarily lower the probability of their use. If a power feels that conditions warrant an attack on a satellite, it will be as likely to carry out that attack if it has one weapon as if it has 100. A decision of that magnitude will be a response to many internal and external pressures. "It isn't going to happen by itself," and if it is deemed to be necessary it may as likely happen with an improvised system as with a dedicated one.

An ASAT attack scenario which has been widely discussed involves attacks on the satellite-borne sensors that provide the U.S. early warning of a Soviet first strike. One participant minimized the importance or plausibility of such an attack scenario. A Soviet attack on warning sensors to prevent a preemptive or "launch-under-attack" U.S. strike might instead trigger that strike. So, if it were not to reveal an imminent Soviet nuclear attack, any Soviet ASAT attack would have to be nearly simultaneous with the launch of the ICBMs that it was intended to mask. Since any direct-intercept ASAT would take several hours to climb to the U.S. early warning sensors at geosynchronous altitude (no existing ASAT is presently capable of getting that far), only yet-to-be-developed directed-energy weapons or pre-emplaced space mines would present a significant threat in this scenario.

At any rate, the United States does not rely solely on early-warning satellites for notification of impending attack. Ground-based radars provide a backup, and for submarine-

launched missiles they give negligibly less warning time than space-based sensors. Ground-based radars can also be supplemented by ship-borne, air-borne, and rocket-borne sensors.

CONNECTIONS BETWEEN ASAT AND BALLISTIC MISSILE DEFENSE

There are quite significant strategic and technological links between anti-satellite weapons and ballistic missile defense (BMD) systems. ASAT issues are central to BMD, and while consideration of BMD is less crucial to analysis of ASAT per se, the two subjects have significant overlap.

One connection is that any effective BMD (except for local, low-altitude site-defense systems) is an even more effective anti-satellite weapon. Even a poor BMD can have significant ASAT capability since satellites are much easier to destroy than missile reentry vehicles (RVs). A system used for ASAT would face at most a few dozen targets, and therefore could take much more time to attack a satellite than a system used for BMD could allocate to each of the up to 1,000 ICBMs or thousands of warheads in a massive attack. Satellites are intrinsically more vulnerable to damage than are RVs, and in a great many ASAT scenarios, attacks on satellites would take place in a much less hostile environment than the nuclear war in which a BMD would have to operate. Furthermore, an orbiting satellite's trajectory is completely predictable, except for limited maneuvers, making a satellite in effect a fixed target.

A second link between ASAT and BMD is that BMD systems (again with the possible exception of local site-defense systems) have space-based elements which would be vulnerable to ASAT attack. Even if a BMD system did not use weapons based in space, it would likely have space-based sensors and communications links; any BMD system intended to attack ICBMs during their boost phase necessarily would require space-based sensors to detect missile launch. If BMD weapons systems were put in orbit, they would be ideal targets for each other. They would be large, expensive, and hard to miss. All indications at present are that space-based weapons would be much cheaper to destroy than to replace "probably by a factor of 10. Right now it looks like a factor of 1,000." On the other hand, they might be capable of self-defense once they became operational.

As ASAT technology is perfected, it will become increasingly unrealistic to deploy "anything that's space-based and expensive." Conversely, if BMD technology is significantly developed, it will severely constrain the possibilities for ASAT arms control, but it might also elevate strongly the incentive for ASAT arms control.

PROSPECTS FOR VERIFICATION

The issue of verifying compliance with an ASAT accord occupied much of the later workshop sessions. Panelists agreed that a total ban on **anything** having any ASAT capability would be both infeasible and unrealistic considering that residual ASAT capability (ICBMs, manned spacecraft, etc.) will invariably remain even if all **dedicated** ASAT systems are banned. There was also considerable agreement, though, that the extensive testing program necessary to develop and acquire confidence in an advanced ASAT weapon would almost certainly be detectable, and that a ban on such testing would require less extensive verification measures than a ban on possession. These issues are discussed further elsewhere in this report (p. 39 ff.).

"RULES OF THE ROAD"

Another important point developed in later sessions was the concept of "Rules of the Road" or "Utilization of Space" agreements. Whether or not some agreement limiting ASAT weapons or testing is desired or implemented, panelists saw a use for an agreement between the United States and U.S.S.R. which would allow each party to continue its use of

space without unnecessarily threatening the other. The United States and U.S.S.R. are each likely to conduct space activities which will appear provocative to the other, and some arrangements for reducing uncertainty might be helpful. The form of such an agreement was not discussed in detail; some additional discussion is reviewed in later sections of this report.

PRESENT TECHNOLOGY

The panel agreed that present ASAT technology (both Soviet and U.S.) is limited in significant ways, and that developing systems free of these limitations would require testing programs which would almost certainly be observable. Both existing systems (the Soviet system and the U.S. system undergoing tests) are only capable of reaching low earth orbit (on the order of 1,000 km)—neither can reach important satellites located at geosynchronous orbit (36,000 km). Both systems have inherent time delays, in waiting for targets to come within range of the launch site and in reaching their targets once launched. (The U.S. system, however, is significantly less constrained in these respects.) Both systems leave intact the adversary's ability to launch ASATs. There was general agreement that present ASAT weapons are much less threatening, and much less destabilizing, than what could be deployed in a new generation of ASATs, including ones which could attack many targets promptly and which could reach geosynchronous orbit.

As an example, one panelist posed the case of both the United States and U.S.S.R. having constellations of space-based beam weapons. As mentioned previously, such systems would likely be targeted at each other. Whichever side attacked first would not only retain its own ASAT (or BMD) capability but would eliminate its opponent's. This extreme incentive to attack first would be highly destabilizing.

Another participant took issue with this scenario, stating that the systems would likely operate so that such an attack by one side would result in most of both constellations being destroyed. For instance, one party detecting an attack could detonate space mines trailing its opponent's systems. All panelists agreed, however, that the present systems are not as threatening as future ones could be.

Descriptions, Pros, and Cons of Possible Agreements

FOCUSES AND PHILOSOPHIES

Before the United States undertakes to negotiate a treaty, it must determine that a treaty would be desirable. Could there be a treaty which would be in our interest, recognizing that Soviet interests do not coincide with our own? We then need to ask whether such a treaty might also be in the Soviet interest. If not, it is pointless to continue. It is not sufficient to find a single set of actors on each side that would be in favor of a treaty. In order to be acceptable, a treaty must be desirable to a large number of players on each side.

Early in the workshop, a panelist questioned whether anti-satellite weapons were indeed an appropriate focus for arms control. He pointed out that the technology and concepts are still being developed. Furthermore, given that some residual ASAT capability will always exist, one can't deny a country the ability to destroy satellites. Although an ASAT arms control accord might include some desirable features, the panelist felt that those goals might better be pursued in association with other arms control ventures.

Another panelist stated that an ASAT agreement would greatly increase the security of our satellites by limiting the development of new ASATs that could be considerably more sophisticated than the present systems. Such an agreement would make the task of protecting our satellites much easier. We must compare the residual ASAT capability under a treaty with the threat to our satellites in an all-out ASAT competition, he pointed out.

One panelist felt that we should be seeking a stable stopping point to the ASAT competition, or at least some intermediate points that would slow down the race, reduce tensions, and lend themselves to further negotiation. In particular, some concern was expressed about the U.S. ASAT being deployed without sufficient consideration of its long-term or possibly irreversible implications. An interim accord would provide some time.

Many participants supported the idea of finding ways to prevent "provocative and inflammatory" activities in space. Panelists realized that both the United States and the Soviet Union will continue to utilize space in ways which might have great potential for creating uncertainty and misunderstandings. This possibility could be mitigated by an arms control agreement. "Survivability is not the only goal" of a space arms control agreement, suggested a panelist, "and in my mind not even the main goal." He explained that the case for arms control really rests on the Soviets' desire to come to some working agreement with us so we both can develop space capabilities "without coming to clashes or crises or problems." This panelist supported a "rules of the road" agreement which would "provide some limit on activities which are going to pose major puzzles" to both the United States and the U.S.S.R. This form of agreement might or might not include an ASAT ban.

We and the Soviets tend to legislate the norms of international conduct by our actions and our agreements, noted a participant. In this manner, we have, for example, in effect declared that "offensive nuclear weapons are okay to have," but that "they're not okay to use directly in a threatening manner in crises." Regarding anti-satellite activity, we have so far "pretty much legislated that it's okay to live and let live in space."

"An ASAT treaty," he continued, "ought to reinforce that healthy kind of approach to space."

PHILOSOPHICAL DIFFERENCES

A point which was readily recognized at the workshop, but was not discussed or debated in depth, was that disagreement about the value of an ASAT accord stems from deeper philosophical differences about arms control in general.

Putting it a little simplistically, treaty proponents feel that our national security will be better with an ASAT treaty than without one, and that such a treaty can be verified well enough to ensure our security. Treaty opponents, on the other hand, focus on possible asymmetries in the relative costs and benefits of a treaty to the United States and to the Soviet Union. The Soviet Union, they feel, would benefit more from United States compliance than the United States would benefit from Soviet adherence with possible cheating. They feel that arms control is appropriate only if it would be advantageous to the U.S. in spite of this inherent asymmetry.

Is the criterion for negotiation that we end up better with a treaty than without one? Or, is it rather that our position with respect to the Soviets be better with a treaty than without one? Similarly, there are differences in overall attitudes concerning space and space arms control. Some view deployment of space-based or space-directed weapons as the breaking of a de facto political taboo, which would not only make the world more dangerous but would also be difficult to reverse. Alternatively, any space arms control treaty could be seen as a political and psychological barrier to the wider exploration and exploitation of space as a theater of military operation.

ASAT LIMITATION TREATIES

In discussing possible forms of ASAT arms control, the panel categorized five types of ASAT arms control agreements:

1. Bans on all testing, use, and possession of all ASAT capability.
2. Bans on all testing, use, and possession of dedicated ASATs.
3. Bans on use and testing, but not possession, of dedicated ASATs.
4. Bans on development or use of new types of ASATs; no restrictions on existing ASAT systems.
5. Bans on use of ASATs; no restrictions on possession or testing.

Panelists readily agreed that the first type of agreement is unattainable. Some non-ASAT systems have some capability to serve as ASATs, so residual capability would remain even if dedicated ASAT systems were banned. Recognizing this fact, the second type of agreement would deal only with dedicated, and presumably more threatening, ASAT systems.

Most of the workshop discussion about ASAT limitations involved a testing ban which might or might not include existing systems and which might or might not prohibit ASAT possession. Testing of a dedicated ASAT weapon would be more visible, and less ambiguous, than its possession. To avoid some of the difficulties of a more extensive ban, a treaty could permit possession of ASATs but ban use and testing. Without testing, the significance of possible ASAT possession might decrease with time. In the view of some, new systems could not be relied upon, and confidence in existing systems would slowly degrade.

The fourth type of agreement, conceding the existence and operation of existing systems, would still restrict the deployment of new and more threatening ASATs. It would also suppress the question of residual ASAT capability, since if both sides had a dedicated system it is unlikely that either would use "baling-wire" systems. Considering the disparity between the U.S. and the Soviet ASATs, though,

several panelists felt that the Soviets might not be willing to concede to the United States the right to test and deploy the air-launched MHV ASAT without reserving the right to develop a system at least as effective.

The fifth type of agreement in the above list would prohibit the use of ASAT weapons and might also delineate acceptable behavior by codifying some set of "rules of the road." Such measures attracted much interest among the panelists as supplements to, as well as alternatives to, ASAT limitations. Proposed agreements of this sort are not as well defined as prohibitions of ASAT testing or possession, for which draft treaties have been prepared by various parties.

ASAT ARMS CONTROL: PRO ARGUMENTS

ASAT treaty proponents see an ASAT arms race as not serving our best interests. "The burden is always on arms control to explain how the world is going to be better with the treaty than without," remarked a panelist, "and the burden is never on the person who just wants to keep blundering ahead to explain how the world is going to be safer that way." Treaty proponents see continued ASAT competition as unwise, and believe that a treaty would be worthwhile even if it served only to constrain future developments. Observing that the ASAT problem will not disappear completely, with or without a treaty, one panelist noted that "in the absence of restrictions, the problem is going to get a great deal worse."

Offense Dominance.—An ASAT race is not desirable because, for the foreseeable future, the offense will always win. Satellites are expensive, and they are inherently vulnerable because of their known trajectories, their limited numbers, and their fragility. Significant cost and performance tradeoffs are required to protect satellites against attack. Therefore, U.S. satellites are likely to be much cheaper to destroy than to replace. This balance will not be changed by deployment of a U.S. ASAT weapon, even if it is superior to the Soviet ASAT. Assuming that we need our own satellites much more than we need to attack Soviet satellites, treaty proponents believe that we should attempt to negotiate a mutual limitation on ASATs.

Defense and Possible Future Developments.—Arms control proponents particularly saw great value in ending the ASAT competition as soon as possible. Current technologies are relatively primitive compared to future possibilities, which could be very threatening. It is easier to protect satellites against the current threat than against subsequent generations of ASATs. The later that action is taken, the more systems will be deployed, the more complicated the technology will become, and the more difficult compliance with any treaty will be to verify. Adequately verifiable testing bans are possible, proponents feel, and they would severely limit the development of truly threatening anti-satellite weapons. The ASAT competition has not progressed so far that stopping now would be irrelevant.

We are now at a stage in which only our low-altitude satellites might be vulnerable, and we face the quite possible future alternative of having our entire in-orbit force structure subject to prompt destruction. Directed-energy ASAT weapons, for example, will very likely be deployed if there is no ASAT accord. Such weapons, having long ranges and near-instantaneous reaction times, would be destabilizing—especially if based in space. If such systems were developed by either or both sides, they would be tempting targets, and each side would have great incentive to attack first in order to disarm its opponent. In the absence of an ASAT accord, we are also likely to see the advent of space mines, which could be comparatively inexpensive. If space mines were widely deployed, most or all of our important satellites would be subject to almost instantaneous destruction.

Existing Unreliability.—Future ASATs will likely be much more reliable than the present systems, which has significant implications for stability. Neither the existing Soviet ASAT nor the U.S. ASAT under development can presently be considered highly reliable. The

U.S. weapon has never been tested against a target in space. According to published reports, the Soviet weapon has not functioned properly in a significant percentage of its tests. Some panelists did note, however, that without knowing the nature of and responses to these failures, we can not necessarily infer a reduced confidence or lower reliability of the Soviet ASAT.

Highly reliable ASATs, if they existed, might increase the risk that low-level crises would escalate. As discussed in the overview, confidence in the ability to attack a threatening satellite easily, quickly, and precisely may increase the likelihood of doing so. In a tense situation, posited one panelist, the United States or the U.S.S.R. might initiate ASAT conflict by reasoning "we're not going to kill anybody; we're not going to threaten anybody's strategic warning system, but nobody's going to take pictures of us for a few weeks now." Both the temptation and the danger of an ASAT attack against a reconnaissance satellite in a crisis would be "extraordinarily high."

Economic Pressure.—A panelist noted that ASAT limitations could forestall utilization of ASAT competition by the Soviets as a relatively low-cost means of applying pressure to the United States. Perceiving a full-scale military buildup by the United States, but constrained by the performance of their own economy, the Soviet political leadership may seek ways to pressure the United States without having to engage in an across-the-board response. In most cases, the development, or improvement, of an ASAT system is much cheaper than protecting against ASATs by duplicating or supplementing space assets.

Mutual Benefit to Treaty.—ASAT arms control advocates noted that ASAT arms control negotiations are not a "zero-sum" game. Both the United States and the Soviets would benefit from an ASAT accord. Soviet interest in negotiations does not mean that we must a priori oppose them. "Certainly you can't expect the Soviet Union to sign any agreement which works to their net disadvantage," explained a panelist, "but most people regard the elimination of nuclear war, or even the significant delay, decade by decade, of all-out nuclear war, as being to the advantage of the Soviet Union as well as the United States."

Private Sector Concerns.—One argument which has been made in favor of ASAT arms control found no support at the workshop. In the past, it had been argued that without an ASAT accord, private industry would be reluctant to invest in space systems which are inherently vulnerable to ASAT attack. Panelists pointed out that the Soviet's current capability to destroy anything in the United States or at sea has not affected the private sector. They noted, as an example, that the Soviet ability to shoot down airliners "which has been demonstrated" has not affected airline investment decisions.

A concern of private industry which was backed up at the workshop is the problem of space debris from ASAT weapons test. Studies mentioned at the workshop indicate that a significant source of debris in low-altitude orbit is Soviet ASAT testing and ASAT-related activity. ASAT tests at or near geosynchronous orbit would be of considerable concern to communications satellite companies.

ASAT ARMS CONTROL: CON ARGUMENTS

Much opposition to ASAT treaty efforts stems not from the desire to have ASAT weapons but rather from the viewpoint that arms control is not an effective or appropriate means of addressing the ASAT question.

Residual ASAT.—ASAT treaty opponents raised the problem of residual ASAT capability—means for destroying satellites which would be infeasible or unrealistic to eliminate by any form of agreement. They also noted that methods for interfering with the operation of systems using satellites, short of destroying them (jamming, spoofing, or attacking ground stations or support facilities), might be difficult to address in an ASAT arms control accord.

Asymmetric Societies.—The asymmetrical nature of the Soviet and the U.S. societies, according to arms control opponents, implies that there will be asymmetric advantage from any symmetric treaty. The Soviets are much more likely than the United States to cheat on an agreement, and if they do cheat they are much more likely to get away with it. Furthermore, there seem to be differences between the United States and the Soviet Union in interpretation of "borderline" activities—"I think we have learned over the last twenty years that the way the Soviet Union keeps a treaty is not exactly the way two-thirds of the Senate had in mind," summed up one participant.

Verification.—Treaty opponents are very concerned about the verifiability of compliance with an ASAT accord. No treaty, of course, is perfectly verifiable, but different people assess differently the likelihood (or significance) of activities which may escape detection. Inventories of ASAT interceptors on the ground or the contents of satellites in space may be difficult to monitor. Compliance with bans on ASAT interceptor testing may be difficult to verify since there are many legitimate activities requiring rendezvous in space which could be made to be partial tests of ASAT interception capability. Furthermore, even a small amount of Soviet cheating in an ASAT arms control agreement could be significant since U.S. satellites are long-lived, valuable, and limited in number. We would be more sensitive to loss of a few satellites than the Soviets, whose satellites have shorter lifetimes and are consequently replaced more frequently.

Limits on U.S. Strengths.—More general objections to ASAT arms control result from the constraints it would put on the ability of the United States to exploit its technological expertise. By permitting the Soviets to "make up lost time" in developing advanced ASAT technology, said a panelist, ASAT arms control would "allow the Soviets a major competitive advantage."

Both the United States and the Soviet Union have too great an interest in the military use of space to agree to an ASAT treaty that would deny the ability to engage in conflict there, he explained. "If there is conflict, there is going to be conflict in and from space. It's inevitable because of what we've been doing for about the last twenty years" by putting very valuable systems in space and using them to the extent that we do.

Ballistic Missile Defense. Another very significant source of opposition to ASAT arms control is the desire to investigate advanced ballistic missile defense technologies. Some of the concepts most attractive to BMD supporters involve "boost-phase" defenses which attack missiles as they climb out of the atmosphere. However, since effective boost-phase weapons would likely also be effective against satellites, they would almost certainly have to be restricted under an ASAT accord which limited the most threatening ASAT technologies. Systems capable of doing boost-phase BMD would be inconsistent with the existing 1972 ABM treaty, but supporters of BMD research may not wish to contend with a restrictive ASAT accord as well. An opinion expressed at the workshop was that "the ABM treaty is bad enough to have as a complicating factor in any type of transition towards strategic defense without adding a layer of porous ASAT agreement."

Difficulty.—A more pragmatic reason for opposing ASAT arms control is that the process of negotiating such a treaty with the involved executive agencies, with the Soviets, and with the Congress is "incredibly painful" and not worth undertaking in the absence of an overwhelming conviction that it would be in the national interest.

ASAT WEAPON: PRO ARGUMENTS

Those opposing an ASAT treaty believe that ASAT arms control is not in the national interest. They may also believe that having an ASAT weapon is in the national interest. Anti-ASAT treaty arguments and pro-ASAT weapon arguments, although related, are distinct.

Three justifications for developing anti-satellite weapons were reviewed at the workshop. Of the three, one was mentioned but not discussed in detail, and another was not supported by ASAT proponents on the panel.

Attack Hostile Satellites.—The primary reason for developing an American ASAT weapon is to deny the use of space to an adversary during conflict. The particular example cited by administration officials and by workshop participants is the threat posed by Soviet ocean reconnaissance satellites which are said to be able to locate U.S. Navy ships on the high seas. Those holding this view do not wish to allow the Soviets freedom to conduct reconnaissance activities from space which threaten American forces. They also expect that the Soviets will utilize other space assets for improving the effectiveness of their military forces ("force-multiplication") and want to be able to deny the Soviets these capabilities as well.

An American ASAT weapon could be stabilizing, it was argued, if used against Soviet reconnaissance satellites which would otherwise be available for retargeting Soviet missiles. In a "shoot-look-shoot" scenario, Soviet reconnaissance satellites would be used to locate U.S. military targets that had survived a first strike. This data would be used to retarget a Soviet reserve force to destroy those remaining targets. The Soviets likely know that they would probably need "more than one echelon of strategic attack" to carry out an effective strike against the United States homeland, argued a panelist. Denying them this "shoot-look-shoot" capability would make it harder to conduct an effective first strike, lessening its probability and therefore increasing stability.

Support Negotiations.—A second reason mentioned at the workshop for developing a U.S. ASAT weapon would be use as a "bargaining chip" to induce the Soviets to negotiate an ASAT treaty. Whether or not this viewpoint may motivate development of some weapons systems, it does not properly belong in a tabulation of "pro-weapon" arguments. If one seeks to negotiate a ban on ASAT weapons, for example, then one presumably has already determined that having an ASAT weapon is not necessary.

Deterrence.—The third reason given for having an ASAT weapon is to deter ASAT attack. This rationale was not supported at the workshop. Arms control supporters and opponents both felt that the ability to retaliate against terrestrial targets served to deter ASAT attack at least as well as the ability to retaliate against satellites. Satellites can be protected against ASAT attack in a number of ways, and having the capability to respond in kind was not thought to be singularly effective in protecting satellites.

A panelist also pointed out that the deterrent role of an ASAT is in opposition with, not in support of, the role of eliminating hostile satellites. If an ASAT capability is required in order to support objectives (such as preventing detection of naval surface units by Soviet satellites) which are unrelated to retaliation, then the deterrent value of an ASAT must be balanced against its potential use in initiating space conflict to attack hostile satellites.

"RULES OF THE ROAD"

Many panelists, including supporters of ASAT limitations as well as those questioning the effectiveness or utility of ASAT bans, agreed that some sort of international agreement concerning "rules of the road in space" could be beneficial. These rules could also include rules on space-related ground activities. While the nature of such an agreement was left vague, and the negotiation process which might conclude in such an agreement was not analyzed, several motivations and possible examples for such an agreement were raised.

Rules of the road would try to alleviate situations which either side would consider particularly dangerous. For example, they might inhibit effective placement of space mines by establishing a minimum separation between satellites. As both sides continue their operations in space, such rules may become increasingly valuable.

One of the functions of a regime of rules in space would be to reduce instances where seemingly dangerous activities are observed without the means of finding out exactly what is going on. Certain activities which might be provocative could be prohibited, or they might be required to be accompanied by an explanation, perhaps in advance, which had some basis for being believable. The most important function of such an agreement, suggested one panelist, might be the establishment of a forum where questionable activities could be discussed. That the forum would help maintain an ongoing dialogue between the United States and the U.S.S.R. would be healthy in and of itself. Alternatively, said another panelist, it would be nice to know that if the Soviets do something that we find very threatening, they did it on purpose. "We might still find ourselves getting dangerously close to a war, but at least we would know better where we stood." A panelist also pointed out that besides defining acceptable conduct, "rules of the road" might also give some basis for responding to certain violations.

A precedent for "rules of the road" is the ban in the 1972 ABM Treaty prohibiting interference with the national technical means used by each side to verify compliance with that treaty. This measure is a "function ban": it does not refer to satellites or space in particular, but rather prohibits interfering with the function of verification. Such a function ban might be extended by building upon the example of the 1971 "Agreement on Measures to Reduce the Risk of Outbreak of Nuclear War," which requires the United States and the U.S.S.R. to notify each other "in the event of signs of interference with [early warning systems] or with related communications facilities, if such occurrences could create a risk of outbreak of nuclear war." This clause could be strengthened to prohibit interference with the function of early warning in general without reference to satellites or ASATs. A very important motivation for rules of the road would be the recognition, such as that implicit in the 1971 Measures Agreement, that accidents will happen.

An additional model could be the international regime existing on the high seas, in which certain particularly hostile and dangerous activities have been banned. Similar bans could be applied to space activities. However, since the "rules of the road" on the high seas as they currently exist do not keep ships out of lethal range of each other, similar rules would not be sufficient to ban space mines. New measures would be required if it were desired to eliminate the threat of space mines by keeping satellites apart by more than a lethal distance.

"Rules of the road will not prevent ASAT attacks," pointed out one panelist. "Perhaps they can't even be verified very well. . . . Nevertheless, an agreement along those lines might be worth having precisely because it would reduce ambiguous acts" and minimize the chances of escalation or misunderstanding in a crisis. Panelists agreed that "rules of the road" would not require an ASAT ban; some of those supporting an ASAT accord felt that it would be strengthened by rules of the road; those opposed to an ASAT agreement saw merit in rules of the road as an alternative.

All panelists agreed that the Soviets are increasing their utilization of space, including their development of ASAT capability. That fact, taken with their willingness to negotiate space arms control with the United States, can be seen as indicating that they would like to jointly draw up some general rules of behavior. "If that's the signal, that's a very interesting signal," interpreted a panelist. "It makes it that much more useful to look for ASAT treaties that simply have the merit of putting some kind of terms of agreement on record, if nothing more."

GENERAL DISCUSSION

There was no agreement on how much the ASAT threat would be reduced by a treaty, or on the significance and likelihood of residual or covert ASAT activity. An important point is the extent to which residual, possibly covert, ASAT systems would place our spacecraft at risk under a treaty regime. "Is it going to be closer to one-eighth of the original threat or is it going to be closer to seven-eighths?" asked one participant.

GRANDFATHERING EXISTING SYSTEMS

The discussion of possible ASAT limitations, their advantages, and their disadvantages touched on a number of issues. One of these was the question of "grandfathering" existing ASAT systems: Should the Soviets be permitted to keep their system? Should the United States be permitted to continue developing its own? One panelist felt strongly that the objective of a treaty is to prevent the development of technologies and capabilities which are much more threatening than those existing now. Such a treaty would block the "sustained, organizational effort" required to implement such advances in ASAT technology. Existing systems, which are not nearly as threatening as future ones could be, might be grandfathered in such a treaty. Alternatively, further testing and development of existing systems could be banned, especially at higher orbits.

One panelist felt that the Soviets would not accept an agreement which would permit existing systems because of the asymmetries in capability between the U.S. and U.S.S.R. ASATs. The U.S. F-15 system, a far more capable weapon, will be able to destroy Soviet satellites much more rapidly than they could be replaced and would be sufficient to deny the Soviets access to low earth orbit for a considerable period of time. Given the Soviets' present technique for attaining higher orbits by using lower altitude parking orbits, the U.S. ASAT could effectively deny the Soviets the ability to reconstitute higher orbit systems as well.

Another panelist was skeptical about negotiating away the Soviet ASAT because of the measures that would be required to give the United States assurance that it had been dismantled. The Soviets have "only in a sort of Aesopian way" admitted that the present SS-9 based ASAT exists at all, he said, "which is not a hopeful way to start out on the negotiation" concerning the "extraordinary measures" required to ensure that the system had been dismantled. However, if the Soviet ASAT is neither eliminated nor balanced with a symmetrical U.S. capability, then the political viability of any ASAT accord in this country would be "very, very low."

U.S. ASAT REQUIREMENT

Another issue stimulating considerable discussion was the need for a U.S. ASAT weapon. There was widespread disagreement about the requirement for an American ASAT to deny the Soviets the ability to target the U.S. fleet with their ocean reconnaissance satellites. There were no panelists with Navy backgrounds ("we've been sinking the Navy without its representation," noted a participant), but at any rate there was little support for the position that the Radar Ocean Reconnaissance Satellite (RORSAT) is an extremely threatening system. The capability to destroy Soviet reconnaissance satellites is neither necessary nor sufficient to protect the U.S. fleet, it was pointed out. The United States has many ways to deny the Soviets intelligence from these satellites—RORSATs are vulnerable to a variety of electronic countermeasures. Studies made more than 10 years ago laid out a "long laundry list of things that could be done other than blowing it up," such as decoying and jamming.

Furthermore, there are many ways the Soviets can locate American ships without the use of RORSATs. "For instance, they can ask

38-036 O - 84 - 86

their own ships, which accompany our aircraft carriers," pointed out a panelist. "If they didn't have radar ocean reconnaissance satellites, they would have other things."

Also disputed was the argument that a U.S. ASAT would be stabilizing since it would deny the Soviets the ability to execute a "shoot-look-shoot" attack. That rationale is an example of the "impractical war conduct scenarios" which one can set up and then show to be impossible if only some particular weapon is built, a panelist said. "That is not a valid reason to oppose ASAT treaties."

Finally, the argument that a U.S. ASAT weapon is needed to induce the Soviets to negotiate was also challenged. "It is not supported by historical experience," said a panelist. "In 1978 and '79, the negotiations [with the Soviets on anti-satellite weapons] were very active and were moving along nicely, and we didn't even have a paper program—much less a system." He pointed out that the Soviets "accepted it on faith" that the United States was quite capable, technologically and industrially, of putting together a system if it wanted to. "If both parties feel they can't negotiate except from a position of strength, the conclusion is there will be no negotiations."

LIMITATIONS OF ASAT ACCORDS ON BMD DEVELOPMENT

According to some panelists, the effects of an ASAT accord on the future development of ballistic missile defense are some of the most important anti-treaty arguments. "They involve important issues of judgement." While it was in effect, an ASAT accord would prevent development and deployment of space-based ballistic missile defense, said an accord supporter. However, any such treaty could have provision for periodic review. Treaties can be mutually eliminated or unilaterally abrogated; they contain "all kinds of possibilities for not constraining ourselves for the indefinite future." However, another panelist countered that treaties "tend to become sacrosanct." Any attempt to withdraw from an ASAT accord would become a "major political football" which might obscure strategic considerations.

URGENCY

One of the most important points raised by treaty supporters was that, if an agreement is to be reached at all, there is great value in reaching it sooner rather than later. A treaty may be much harder to negotiate, and be much less effective, if it is delayed. In particular, many treaty proponents thought it would be "extremely damaging" to complete tests of the U.S. air-launched ASAT because the Soviets will react to that development. If, following future American tests, the Soviets believe the U.S. system to operate reliably, they may not be willing to concede the United States' right to keep that system without demanding that they themselves be permitted to match or exceed that system's capabilities. "Quit while you're behind," urged a panelist, "or while you're nominally behind." In another panelist's words, "negotiating from strength is a sinusoidal function and you have to pick your timing right. . . . We should be negotiating now because we are behind by just the right amount."

In arguing for an agreement as soon as possible, one panelist noted that the negotiations need not take a long time. "You do not have to negotiate the ultimate ASAT agreement, and the best agreement to negotiate first is the broadest one." Another panelist countered that while an agreement need not take a long time, it probably will take a long time for reasons which are more political than technical. "If you don't want an agreement and you don't go to the table, it is likely to take a very long time" to negotiate and conclude a treaty.

Soviet Attitudes and Efforts

MILITARY EFFORTS

PAST DEVELOPMENT AND PRESENT STATUS

The Soviets have attached a great deal of significance to space activities. Their programs, controlled by the military, are a source of great national pride and have tremendous momentum. They have pursued all of the military support activities in space that the United States has undertaken, often for reasons not clear to American observers. The U.S.S.R. has also exploited options that the United States has forgone.

Development of the current Soviet co-orbital ASAT began in the 1960's for reasons which "really kind of remain something of a mystery" and quite possibly were not thought through in depth. It is not presently a very capable weapon. "I don't think that the orbital intercept system is of great military significance," said a panelist, echoing views which were widely shared at the workshop. "Indeed, it's hard to imagine exactly what threat it does pose." However, the Soviets have been taking the system very seriously. They have maintained it, tested it, and improved it over the years. They have not made major advances or introduced significant variants of the co-orbital ASAT, but instead have been systematically making incremental modifications. A panelist warned against drawing too many conclusions about the lack of major upgrades in the Soviet ASAT. The United States had maintained nuclear-armed ASAT interceptors on islands in the Pacific Ocean for 12 years without upgrades. We chose to develop an entirely new system—the air-launched direct homing interceptor—because that type of system had clear advantages. "There is no reason to suppose that the Russians might not have made a similar decision."

One must be careful in comparing the Soviet and the American space efforts. Many qualifications are required in order to determine true Soviet capabilities or level of effort. When comparing launch rates, for example, one must recognize that Soviet satellites are much shorter lived than American ones. Although the Soviets had 98 launches (military plus civilian) in 1983 compared to 22 for the United States, during that time the United States had about twice as many active satellites in orbit as the Soviets.

To some extent, the Soviet approach of having more but shorter-lived satellites reflects the Soviets' poorer technology; nevertheless, it does give them some significant strengths. They have replacement satellites and launchers and will be able to reconstitute space systems quickly in case of ASAT attack.

"The Soviets would fare better than we would in an environment in which satellites had an 'enemy-induced lifetime' of two weeks," said a panelist. "They would hardly notice it whereas it would hurt us a lot." However, he noted that if the United States deploys its ASAT, it will be able to destroy Soviet satellites within a few hours of launch. The Soviet ability to replace satellites every few weeks would not be very useful.

At present, the United States is seen by many observers as being more dependent on space systems than the Soviet Union. However, as the Soviets increase their use of space support systems, any asymmetry between Soviet and American reliance on space will lessen. Indeed, one panelist felt that the Soviets are now "fully as hooked on the use of those systems as we are," and that they are clearly using space systems in connection with their Afghan and other military ventures.

SPECULATION ON FUTURE DEVELOPMENTS

Future Soviet space activities are certain to increase and will appear provocative to many observers in the United States no matter what the "real" explanations may be. The Soviets will be undertaking "all sorts of operations at a level substantially higher than we're going

to be involved in." The Soviets are reportedly doing research and development into directed energy weapons, and at least one participant gave "considerable credence" to the notion that the Soviets might launch a space laser later in this decade. Such a device, rather than an incremental refinement of their co-orbital interceptor, would be required to deal with the American target set which has many satellites in very high orbits.

Another panelist cautioned that there has been, at times, considerable misrepresentation of the Soviet space program. "They may be working on lasers," he said, and "they certainly work on space." However, there has been "no significant, no credible report" of Soviet space-based lasers. "They could put a laser into space, just as we could," he continued, but it would be "militarily insignificant."

One participant questioned the relevance of speculating about Soviet motivations and developments, and of comparing the Soviet and American systems. "Useful as [that process] might be if better answers were available," he felt, it turns out "not to be a particularly illuminating way to go" in the present circumstances. "Maybe it's a diversion that really isn't very helpful at all."

DIPLOMATIC AND POLITICAL

SOVIET PERCEPTIONS

The Soviets currently say they see the U.S. strategic buildup as representing a desire to achieve and maintain a first-strike capability. Looking for means of countering this across-the-board buildup, the Soviets could see development of their ASAT weapons system as being an effective way to put very significant pressure on the United States with very little investment.

A panelist, attempting to view the American strategic rearmament program from the Soviets' "rather paranoid perspective," noted that the MX, the Trident D-5, and the Pershing II missiles are seen as being the "workhorses" of this presumed preemptive attack. Enduring command and control systems and ASAT weapons would fulfill vital support roles. If the United States were to pursue ballistic missile defense, it would be perceived, from this viewpoint, as enhancing a first strike posture by threatening to blunt Soviet retaliation.

American arms control overtures are also seen by the Soviets as supporting a U.S. first-strike capability, explained the panelist. Our proposals, which would have the effect of reducing Soviet force levels while not constraining the types of weapons programs we are undertaking, would just make it easier for us to undertake a first-strike attack.

POSSIBLE POLICY

The Soviets have stated their interest in resuming ASAT negotiations with the United States. They have been getting diplomatic credit for taking the initiative in promoting space arms control. The Soviets in 1981 and again in 1983 brought draft ASAT treaties before the United Nations. A major factor which seemed to have been a damper on U.S.-U.S.S.R. progress in the 1978 and 1979 ASAT negotiations had been the People's Republic of China's nonaccession to the Outer Space Treaty of 1967. After the OTA workshop had concluded, one of the participants informed OTA that the PRC had indeed acceded to the Outer Space Treaty as of December 1983--an event "of great importance."

Panelists noted that the Soviets have several incentives to negotiate an ASAT treaty with the United States. One is the argument "so frequently employed in American arms control negotiations: 'sure, we can make that proposal because, even though it might not be a good thing if it were accepted, we can count upon the Americans to not accept it simply because we propose it.' " Alternatively, and

contrary to their seeking to engage in an ASAT race to pressure the United States, the Soviets have an interest in limiting ASAT technology because that is an area where the United States might be able to excel. The Soviets are concerned that "we're going to push them into a technological race in areas where we have some advantage."

The Soviets have changed their public position since 1981. At that time, they would have permitted existing ASAT systems to remain under a treaty. Now, they claim that the U.S. weapon is too much more capable than their own to permit such an arrangement, and they will likely seek to ban it or else demand the right to respond with at least as capable a system of their own. A panelist noted that, should the Soviets seek to mirror the U.S. ASAT by deploying an air-launched equivalent, their BACKFIRE bomber would be a "splendid machine" for that purpose. It is large, fast, maneuverable, and can climb to high altitudes; BACKFIRES and their crews and logistical support exist in quantity.

The 1983 Soviet draft ASAT treaty modified or removed many of the features of the 1981 draft which had been considered objectionable from the American point of view. In particular, it did not include explicit objection to the U.S. space shuttle. The Soviets do not find the space shuttle to be an object of "fear and loathing," said a panelist. He dismissed the idea that, using the space shuttle, the United States might "swallow one of their satellites and bring it back to Los Angeles or somewhere and dissect it." "I would strongly suggest that we not try that," he continued. "The first time we try it, we will have three shuttles instead of four."

However, Soviet attitudes concerning the shuttle might very well be modified by use of the shuttle for anti-satellite experiments or tests. *Aviation Week and Space Technology* articles cited at the workshop report that anti-satellite related activity is scheduled for future shuttle missions. Although the Soviets have indicated an understanding of the importance placed by the United States on protecting shuttle activities, including those involving military support, it was felt at the workshop that their tolerance would not extend to active ASAT experiments. One panelist felt that, in reaction to U.S. ASAT activity (shuttle-related or otherwise), the Soviets may go so far as to challenge such long-established precepts as right of overflight of Soviet territory by military-support space systems.

Other panelists made the observation that it would be "very surprising" if the Soviets, in concluding an ASAT treaty, would be prepared to give up the capability to attack elements of a strategic weapons system based in space. This would apply in particular to space-based elements of a strategic defensive system.

A panelist noted that by vigorously pursuing space activities and at the same time seeking space arms control negotiations with the United States, the Soviets could be indicating that they would like to draw up some rules of behavior which would permit them to expand their space activities in a way that is "reasonably safe and reasonably in concordance with what we want to do." Lack of significant progress on their co-orbital ASAT should not be taken as indicative of a desire for arms control. "I don't think that it's useful or that it's likely to succeed to rest the case for arms control on evidences of Soviet restraint. . . . They will restrain themselves when they see a political purpose to it, and the arms control agreement or other agreements provide the political purpose for it." Without disagreeing, another panelist cautioned against attributing to the Soviets the same policy or operational doctrine concerning ASATs as the United States holds. "We have a notion of what we think ASAT development or ASAT arms control would do within the context of American security policy . . . [but] it is not obvious to me that they are going to make those judgments in the same way we do."

U.S. Attitudes and Efforts

BACKGROUND

DEPENDENCE ON SPACE SYSTEMS

The United States has placed high importance on the utilization of space for military support operations. It has developed advanced space technology which is deployed in valuable, sophisticated, and long-lived satellites. Space systems are particularly attractive to the United States in view of its policy of being able to project power worldwide. The high capability and high cost of American satellites, however, tend to make them attractive targets for ASAT attack. We have not expended much effort in the past making these assets redundant or survivable, increasing the motivation for the Soviets to develop an ASAT.

At the same time, the U.S. has recognized the vulnerability of space assets and has not relied on them as extensively as it otherwise might have. For example, the space-based Global Positioning System, when fully operational, will permit increased accuracy of U.S. strategic missiles, but guidance of U.S. ICBMs and SLBMs will not rely solely upon that system. Space systems play a very important role in military support which should not be underestimated, but critical, indispensable systems are designed with minimum dependence on satellites. If space links are involved, they are part of a redundant set of alternatives. As a result, there has not been a strong incentive to develop ASAT weapons.

Possibly more significant than our partial dependence on satellites, thought some panelists, is our moving towards total dependence on the space shuttle as a launch vehicle. "If the Soviets have an interest in impeding or disabling all or some parts of our space program, the way to go to the jugular is to go to the shuttle," remarked a panelist. "The Air Force's claims that there is need for retention of conventional launch capability are absolutely correct."

ANTI-SATELLITE SYSTEMS AND NEGOTIATIONS

In the 1960's, the United States maintained an operational system of nuclear-armed ASAT interceptors at Johnston Island and Kwajalein atoll in the Pacific Ocean. These were decommissioned by 1975 for several reasons, including: 1) the threat of orbiting nuclear weapons, which the ASATs were intended to counter, never materialized; 2) nuclear ASAT detonations in space would damage friendly satellites and terrestrial systems by electromagnetic pulse (EMP) generation; and 3) the existence of the nuclear-armed ASAT system formed a disincentive to spending additional money on a more sophisticated and more usable ASAT weapon. In 1978 and 1979, the United States held three rounds of bilateral negotiations with the U.S.S.R. concerning ASAT weapons. The talks were never resumed following the Soviet invasion of Afghanistan.

PRESENT POLICY

Although administration representatives were invited to participate in the workshop, none did so. As a result, the panelists attempted to represent administration positions from the perspective of outside, interested, and knowledgeable observers, and at times cited administration testimony before the Senate Foreign Relations Committee.

ASAT ARMS CONTROL

Present Reagan Administration policy is to complete development and deployment of the F-15-launched, direct-ascent ASAT interceptor and to defer ASAT negotiations which have been sought by the Soviet Union. Three reasons have been given to Congress for building a U.S. ASAT weapon: 1) The existence of the Soviet ASAT requires that the United States develop an equivalent capability in order to deter Soviet ASAT attack, 2) the United States requires an ASAT in order to compel the Soviet Union to enter ASAT weapon negotiations in good faith, and 3) the United States requires the capability to deny the Soviets use of space assets which support attacks against U.S. forces.

Inadequate verification has been the primary stated reason for the United States not responding positively to Soviet requests to resume ASAT negotiations. Difficulty in verifying the destruction or ensuring the absence of dedicated ASAT systems, and the inevitable existence of potential residual ASAT capability (Galosh ABM interceptors, Soyuz rendezvous procedures, etc.) have been cited as being impediments to treaty verification. Potential residual or covert Soviet ASAT capability has been felt to preclude an effective ASAT treaty. Pursuit of the Strategic Defense Initiative, which would likely be impeded by effective ASAT arms control, may have been a factor in the opposition to ASAT negotiations but had not been brought up in testimony before the Senate Committee on Foreign Relations as of early 1984 (the most recent testimony offered before that Committee had been in May 1983).

ASAT arms control was not seen by the panelists as being high on the incoming Reagan administration's list of priorities. Its most important military objective was to build up strategic forces, and ensuring the survivability of military support satellites was made a very high priority. Strategic Arms Reduction Talks and Intermediate Nuclear Forces negotiations may have been a priority, but ASAT negotiations certainly were not. The possibility of future ASAT talks had not been foreclosed, but it was felt that they could be considered at some future time if they were seen to be in the national interest. For the time being, the Air Force was to continue development of the air-launched ASAT weapon.

A workshop participant noted that it seemed as if there had been no net assessment, at least in the first three years of this administration, of the overall advantages and disadvantages of an ASAT treaty. ASAT was not a priority issue, so there was no motivation for overcoming bureaucratic impediments against "getting the focused attention either of persons who don't wish to agree or of the person who can tell them to." The lack of such a comprehensive policy, if it indeed is missing, is likely due to the lack of ongoing ASAT negotiations. During the 1978-79 ASAT negotiations, there was incentive to formulate an administration-wide policy. "Negotiating with the Soviets was really driving the whole process" at that time, observed a panelist.

ARMS CONTROL IN GENERAL

The Reagan administration reevaluated previous administrations' attitudes towards arms control. It was felt by members of the incoming administration that many previous arms control agreements had not been in the best interests of the United States. Negotiations which had led to treaties had had the effect of codifying and preserving the status quo. Since the new administration felt that the United States was in an unsatisfactory military balance with respect to the Soviet Union, taking into account rates of buildup as well as levels of deployed forces, this imbalance would have to be redressed before there was much hope of successful arms control. "The burden of proof," explained a panelist attempting to interpret administration attitudes, "would be on those who argued that an arms control negotiation about anything was more likely to succeed if begun in 1981 than if begun in 1982 or 1983 or 1984 or 1986 or 1987."

Panelists also perceived an assumption within the administration that it would be a mistake to modify military programs to meet arms control objectives — either to make arms control successful or to rely upon successful conclusion of an agreement. "If a program makes sense in the absence of arms control," voiced a panelist attempting to represent this attitude, "then that program makes sense, and one should not think about the alternatives of either 'go ahead with this program' or 'go ahead with an arms control treaty'."

Administration policies seemed to some panelists to be consistent with an attitude, held implicitly by administration policymakers, that the U.S./U.S.S.R. relationship will be one of military competition for the indefinite future. "It is beyond the ability of policy makers to opt out of that competition," as restated by a panelist. However, "the policymakers may have some choices about where that competition takes place." It would therefore make sense for the United States to steer the military competition into an arena where the United States might excel—developing and deploying sophisticated technology, such as space technology—and away from competitions which just involve spending money, such as putting tanks into Central Europe. Along these lines, there are those who argue that space is where the United States can "outflank" the Soviets and sustain some kind of superiority, and that consequently an ASAT treaty might be one of the less attractive arms control possibilities.

ASAT, BMD, and the 1972 ABM Treaty

ASAT systems and anti-ballistic missile systems are closely related, as are ASAT and ABM arms control. The development of ASATs can affect the continued viability of the existing ABM arms control regime; conversely, development of strategic defensive systems can affect possibilities for ASAT arms control. This section reviews the 1972 ABM treaty ("I have a rule . . . never to be flabbergasted at the same thing more than three times," explained a panelist, "but I am always somewhat surprised at how people forget what it is that the treaty says and what it does not say"). This section also discusses some of the relationships between ASAT and ABM, regarding both weapons systems and arms control measures.

REVIEW OF 1972 ABM TREATY

PURPOSE

The Treaty Between the United States of America and the Union of Soviet Socialist Republics on the Limitation of Anti-Ballistic Missile Systems, which entered into force on October 3, 1972, states its overall purpose in Article I:

> 1) Each party undertakes to limit anti-ballistic missile (ABM) systems and to adopt other measures in accordance with the provisions of this Treaty.
>
> 2) Each party undertakes not to deploy ABM systems for a defense of the territory of its country and not to provide a base for such a defense, and not to deploy ABM systems for defense of an individual region except as provided for in Article III of this Treaty.

This explicit declaration of purpose is an important aspect of the treaty. As time, technology, and circumstances change, it is possible to refer again to the declared purpose in order to develop specific new understandings which are required to modernize the treaty.

DEFINITIONS

An anti-ballistic missile system is defined, for the purposes of the treaty, as "a system to counter strategic ballistic missiles or their elements in flight trajectory." This phrase is followed by the words "currently consisting of" and then a list of three items: ABM interceptor missiles, ABM launchers, and ABM radars. The treaty is not restricted to those systems. It says what the current systems are, but it is intended to cover all ABM systems.

Note that the definition refers to strategic weapons. Systems to counter tactical missiles are not covered at all—"a loophole that we designed carefully, and which they are pushing through," according to a panelist (see app. B). Note also that the treaty defines an ABM as a system to counter strategic weapons. It does not say "system designed to counter," as the Soviets would have liked, nor does it read "system capable of countering," which was the United States' preferred wording. The United States was concerned that, by upgrading surface-to-air missiles (SAMs), the U.S.S.R. would be able to deploy a considerable ABM capability. The Soviet Union, on the other hand, was concerned that it would be forced to classify some 10,000 SAMs as ABM interceptors. The analogy of upgrading ASAT weapons to give them ABM capability is similarly relevant and similarly covered by the treaty.

This definition is essentially a capability test. All systems which are ABM-capable, whether or not they were designed for that purpose, are either considered ABM systems under the treaty or else are in violation of Article VI(a), which prohibits giving ABM capability to non-ABM systems. This article was "really aimed at SAM systems," explained a panelist, "but the same thing applies to ASAT systems." If an ASAT weapon is given the ability to counter strategic ballistic missiles,

then "it's a violation or else it's got to count as an ABM system, one way or the other."

MAJOR PROVISIONS

The ABM treaty prohibits all ABM deployments which are not explicitly permitted. Article III bans all deployments other than two sites (amended by a 1974 protocol to one) on each side, each having restricted numbers of interceptors, launchers, and radars. These prohibitions, interpreted a panelist, are clear: "Can you deploy lasers? No. Can you deploy particle beams? No. Can you deploy squizzle dumps or freeble dobbles? No."

Article IV permits testing, at designated test sites, of certain systems not deployable under Article III. However, systems permitted at test sites or deployments are severely constrained by Article V, in which "each party undertakes not to develop, test, or deploy ABM systems or components which are sea-based, air-based, space-based, or mobile land-based." Only fixed, land-based systems can be tested, and only specified fixed, land-based systems can be deployed. "Development," as referred to in this provision, was defined in a statement to Congress by the chief U.S. negotiator of the ABM treaty: "It is understood by both sides that the prohibition on development applies to activities involved after a component moves from the laboratory development testing stage to the field testing stage, wherever performed." Interpreted by a workshop panelist, "if I see one outside the laboratory—a prototype, a bread-board model—if I see one, it's a violation. I don't have to see it tested." The second part of Article V prohibits a launcher from being able to fire more than one interceptor or be reloaded rapidly.

Upgrades are prohibited in Article VI(a), as discussed above. No non-ABM systems shall be given ABM capability or be tested in an ABM mode. The second part (b) of Article VI restricts ABM battle management radars by requiring early warning radars to be on the periphery of the country and oriented outwards. Agreed Statement F, approved by U.S. and U.S.S.R. delegation heads at the same time that the treaty was signed, excludes radars used "for the purposes of tracking objects in outer space or for use as national technical means of verification" from the location and orientation restrictions in Article VI(b).

Article XII prohibits interference with verification of the treaty, both by banning interference with the national technical means used for verification and by prohibiting "deliberate concealment measures" which would impede verification by national technical means. Article XIII establishes the Standing Consultative Commission to handle questions relating to treaty compliance, to consider possible amendments, and to consider proposals for further limiting strategic arms.

Agreed Statement D of the ABM treaty discusses components based on "other physical principles" and capable of substituting for interceptors, launchers, or radars. Capability, again, is crucial. If a new device can substitute for a launcher, interceptor, or radar, its deployment is prohibited. If it is instead only an adjunct or supplement, it would be permitted. This article specifies that "specific limitations" on such new systems and their components would be "subject to discussion" in the Standing Consultative Commission, and that such discussion might lead to amendment of the treaty. Only if the treaty were amended to permit these new components would their deployment be allowed; otherwise, they are prohibited.

CONNECTIONS BETWEEN ASAT, BMD, AND THE ABM TREATY

As mentioned above, developing an ASAT system which had BMD capability, or upgrading one to give it BMD capability, would be a violation of the ABM treaty. The test of violation is capability—can the ASAT destroy missiles? There is an absolute prohibition on anything not fixed on land at an ABM site or a designated test site which is able to destroy "strategic ballistic missiles or their elements in flight trajectory."

National technical means of verification are protected from interference in Article XII. Reconnaissance satellites are not explicitly mentioned in the treaty text, but they are listed as an example of national technical means in the transmittal letter from the Secretary of State to the President which accompanied the treaty and were also mentioned in the transmittal letter to Congress. ASAT attacks against reconnaissance satellites used to monitor compliance with the ABM treaty are, therefore, banned by that treaty.

Another relevant connection between ASAT systems and the ABM treaty involves the radars required for ASAT battle management (in the absence of an ASAT treaty) or ASAT treaty verification (if such a treaty is concluded). These space-track radars will physically be very hard to distinguish from early-warning radars and ABM battle management radars which are covered by the ABM treaty, and any ASAT treaty may need specifically to address space-track radars to ensure that the prohibitions against ABM battle management radars are not circumvented. However, according to a panelist, the signal emitted by a radar "would be quite different if it were fundamentally a space track system than if it were an ABM," making somewhat easier the task of distinguishing between the two (see app. B).

TECHNOLOGIES

There is great overlap between BMD and ASAT technologies. In general, even a poor or prototype anti-ballistic missile could be an excellent ASAT. Looking at BMD systems designed to attack a ballistic missile at different stages in its flight trajectory, we have three categories of BMD systems:

1. **Boost-phase BMD.**—BMD systems designed to attack missiles as they are climbing out of the atmosphere under powered flight have great ASAT potential. Therefore, any treaty effectively limiting systems having ASAT capability would almost certainly have to restrict boost-phase BMD. Of course, the ABM treaty already in effect prohibits boost-phase BMD: in order to respond quickly enough to attack missiles in their boost phase, a boost-phase BMD system will either require space-basing of weapons components or else it will need to launch "pop-up" components immediately upon detection of missile launch by space-based sensors. It may well also require directed-energy weapons which produce beams propagating at or near the speed of light. "Both of those are prohibited by the ABM treaty," reminded a panelist. "It's not as if there's some little, subtle question as to whether a space-based BMD system would be permitted or not. It's not. You can't develop it, you can't test it, you can't deploy it, and it's caught in about eight different places in the treaty. It is not close."
2. **Midcourse BMD.**—The trajectory of a missile reentry vehicle while outside the atmosphere is similar to a satellite orbit: the peak altitude is on the order of 1,000 km and the velocity is slightly suborbi-

tal. There is therefore great overlap between midcourse BMD systems and ASAT systems. The Soviet Galosh ABM system was not designed as an ASAT but does have ASAT capability for satellites in orbits similar to ICBM trajectories; the U.S. miniature homing vehicle ASAT weapon evolved from a design originally intended for midcourse BMD. Since the ABM Treaty strictly limits locations of permitted ABM systems, there are significant constraints, in terms of number and location, on ABM systems which could be used as ASATs. Including the interceptors at test ranges, each side would have only about 115 interceptors and they would be located between 45 and 60 degrees latitude. ABM systems permitted under the treaty are therefore "important for some kinds of satellites in certain kinds of orbits, in certain places," but they are "probably not a very significant threat" to satellites in general. In addition to the constraints in the ABM treaty, midcourse BMD (like boost-phase BMD) would probably be inhibited by an effective ASAT treaty.

3. **Terminal BMD.**—BMD systems which attack missile warheads after the warheads have re-entered the Earth's atmosphere have the least overlap with ASAT technology. They are also not very useful systems for defending large areas, as opposed to selected hardened targets. While research into terminal BMD systems is proposed as part of the Reagan administration's Strategic Defense Initiative, they are not the systems primarily responsible for the renewed interest in ballistic missile defense pursuant to the President's March 23, 1983 "Star Wars" speech.

ROLES

Since ASAT and BMD technologies are so closely related, the outcome of any ASAT limitation or testing ban will almost certainly impede midcourse and boost-phase BMD development. Conversely, technology development ostensibly for an advanced ASAT system might provide a loophole for undertaking BMD research which would be in violation of the ABM treaty.

At the same time, the development of high-quality ASATs which will probably occur in the absence of an ASAT agreement would put the space-based elements of any BMD system (sensors if not weapons) at risk. Unconstrained ASATs would threaten sensors even for ABM systems which are within the scope of the present ABM treaty.

PERCEPTIONS

As noted above, aggressive ASAT development will aid development of advanced BMD systems since technologies investigated for ASAT may be useful in either role. ASAT development may therefore be perceived as supporting a BMD program. To the extent that development of BMD is seen as being threatening, ASAT development may likewise be perceived to be a threatening act.

In a political context, a participant suggested that some of the hostile implications of pursuing BMD research might be ameliorated by simultaneously pursuing some sort of space behavior or "rules of the road" agreement.

DRAFT ASAT TREATIES

The 1983 Soviet draft ASAT treaty includes a subtlety of language which may or may not have been intended. The phrase "space object" is a negotiator's "term-of-art" originating with the Outer Space Treaty negotiations. It stands for anything in space **except for** ballistic missile reentry vehicles, which were purposely and carefully exempted from the jurisdiction of that treaty. Although the Soviet draft mentions space objects in the introduction, an operative article prohibits testing and deploying "space-based weapons for the destruction of objects on the Earth, in the atmosphere, or in outer space" (emphasis added). It does not say "space objects," implying that attacks on reentry vehicles would not be excluded from

the ban. One participant, noting that the "Soviets are not dummies when it comes to treaty language," thought that quite possibly they intended to use language that was "opaque as to their views" which would "invite us to reveal our views of some of these substantive matters through the route of fiddling around with these language details."

The draft ASAT treaty proposed by the Union of Concerned Scientists, on the other hand, prohibits attacks on "space objects" and therefore does not address the problem of attacks on reentry vehicles. That exemption was made because the ABM problem had been explicitly addressed in the 1972 ABM treaty. "There is a tendency in drafting treaties to make the treaty stand by itself," commented a panelist. "That should be resisted. Every treaty exists in the milieu of other agreements."

At least one participant disputed the value of preparing drafts outside of an ongoing process of negotiation: "I do not like the idea of people putting out draft treaties on ASAT matters." They are invariably "incomplete" since the text alone does not include any of the history that accompanies a true negotiation process and since the authors are not necessarily official representatives of their governments. The "prejudicial effects" of extant drafts "could probably be dismissed in a couple of weeks," but that time could be put to better use should negotiations be resumed.

TREATY WORDING

The language of the ABM treaty was left "fuzzy" in places, and definitions were not made overly precise, in order to leave a "no-man's-land" surrounding prohibited areas. The hope was that debate would ensue as to whether the "no-man's-land" had been entered before there were any questions of treaty violation. This "noble experiment," however, did not provide the desired results. "It turns out the Soviets are creatively legalistic," interpreted one panelist. "They don't worry about the fuzzy areas. In their view, action in a fuzzy area is permitted because it's not prohibited."

However, the suggestion that the Soviets do not uphold the spirit of a treaty was debated by another panelist. "I don't like to talk about the 'spirit of agreement' because there ain't no such thing." However, this panelist noted that there is significant value in having an operative article in a treaty which states the treaty's general purposes. When circumstances change, forcing development of new understandings in order to maintain the treaty, one can look back on that declaration of intent to make an easy transition. "Here is the agreed purpose that's built into the treaty. Here are the new circumstances that bear on that purpose, and here are the new specific understandings that are needed to modernize" the treaty.

Verification Issues

CAVEATS

Verification issues are inherently difficult to discuss in an open meeting. However, a panelist pointed out that verification is much more than a detailed catalog of technical intelligence capabilities. Another panelist agreed, noting that the intelligence agencies say that their job is not verification, but monitoring. They make that distinction very clearly, he explained: "verification" is a political, legal, diplomatic, and military process, of which "monitoring" is only a part.

Workshop panelists started the session devoted to verification by making two observations. First, verification is concerned with determining whether or not specified treaty provisions are being complied with and is therefore inherently dependent on the wording of those provisions. Second, any discussion of verification ought to include consideration of the overall military or security purposes which the treaty is to serve. The level and confidence with which compliance with a provision need be verified must depend on the significance and implications of violating that provision.

GOALS

Therefore, any discussion of verification technology and procedure must implicitly or explicitly be preceded by discussion of philosophy—what is it that the treaty is to accomplish? Five not necessarily mutually exclusive goals of a space arms control or space behavior agreement were identified at the workshop:

1. to reduce the vulnerability of existing space assets to dedicated or residual ASAT threats by constraining those threats;
2. to prevent future development of a high-confidence, high-quality ASAT by the opposing party;
3. to relax tensions between the superpowers by establishing a regime of acceptable behavior in space;
4. to obtain political or diplomatic goodwill; and
5. to avert or constrain an arms race in space.

Some aspects of a treaty may be much more relevant for achieving the principal purposes of the agreement than others, and therefore it may be more important to verify some portions of an agreement than others.

LEVELS OF VERIFIABILITY

Some provisions in a treaty may serve to ban activities which are not very threatening in themselves but are prohibited in order to ensure that other, more threatening activities are not undertaken. In these cases, the activities which are of less concern might not need to be detected with as high a level of confidence as long as there were higher confidence that the more threatening activities were not taking place. As an example, consider a ban against testing ASAT interceptors at geosynchronous orbit, which would be a more threatening act than testing them in low Earth orbit. It might be easier to ban these high altitude tests if tests in low earth orbit were also prohibited. Even if some low-altitude tests were conducted covertly by masking them as legitimate rendezvous operations, the

low-altitude ban might prevent overt, explicit low-altitude ASAT tests which might be more easily adapted to higher orbits than a covert capability would be.

Limitations which might not be highly verifiable, taken alone, might nevertheless be useful in an agreement as long as one understands the limited contributions such bans might make to security. Subversion of even a leaky ban would require a totally covert program, which would certainly be more difficult than an overt one and which may or may not be possible. Furthermore, technical encroachment of a treaty proscription by a single component is not the same as development of a militarily significant system. "Soyuz can ram satellites," admitted a participant, "but you have to have one hell of a lot of Soyuzes floating around to make a terribly militarily effective ASAT system."

The problem of levels of verification has arisen in previous arms control issues. "In the late 1970's, there was some agreement among a large fraction of the community," said a panelist, "that although cruise missile verification could not be absolute, verification could be good enough considering that they did not pose a first strike threat." Another panelist noted that we do not necessarily have to respond to weaknesses in our verification capabilities by either contorting arms provisions to avoid the weaknesses or by avoiding arms control altogether. There are defensive means other than arms control, such as hardening and survivability measures or changes in operational procedures, which can offset the military advantage that might accrue to a party attempting to cheat on an agreement.

FACTORS IN VERIFICATION OF ASAT ARMS CONTROL

COMPLICATIONS

Discussion of ASAT arms control brought forth several factors which tend to complicate the verification of compliance with such an agreement, and several other factors which ease that task. One of the complications is the enormous volume of space where illicit activities might be conducted. Verification of compliance with a SALT or START arms control agreement involves inspection of number of areas within the Soviet Union or its immediate airspace. This area, although vast, is relatively well determined and is amenable to close inspection by space-based photographic reconnaissance satellites. The region where space activities might be conducted starts at altitudes of about 100 km and can range well past geosynchronous orbit at 36,000 km. Also increasing the difficulty of verifying compliance with an ASAT treaty is the large number and growing variety of Soviet space launches. Soviet launches have increased at a rate of about 2 percent per year, averaged over the last 15 years. Although this launch rate may very well decrease in the future as the Soviets develop longer lived satellites, each additional type of satellite requires a body of experience in order to classify its function and permit discrimination between unusual activity and routine behavior.

Third, the functional characteristics distinguishing ASAT weapons or space mines from other satellites may not be readily observable. All national technical means have imperfect discrimination, and the physical differences between permitted and prohibited satellites may be small. As panelists had previously pointed out, much Soviet space activity is not likely to be completely understood by the United States no matter what the "true" Soviet intent might be.

A fourth complication is the inevitable presence of some residual ASAT capability in systems which may be undesirable or infeasible to ban. ICBMs, SLBMs, ABM interceptors, maneuvering spacecraft, and possibly air-

based or ground-based lasers may fall into this category. These systems may pose problems in determining whether they are being operated in an ASAT mode; normal operation (of rendezvous between spacecraft, for example) may be difficult to distinguish from certain types of ASAT activities. This question of residual ASAT capability is one of the most crucial factors in the debate concerning the desirability of an ASAT accord, and just how much ASAT activity could go undetected is a critical question. As the number of systems possibly having some ASAT capability proliferates, the monitoring task of determining how these systems are being used will become even more difficult.

A fifth, somewhat ironic, point made during this discussion was that at present, the principal motivation for the United States to develop the sort of space monitoring capability which would be useful in verifying an ASAT accord is to provide targeting information for the U.S. ASAT weapon. Panelists did note, however, that it is likely that any monitoring capability needed to verify a treaty would be desirable in any case. Intelligence collection requirements would persist even in, or especially in, the absence of a treaty. However, the lack of an ASAT weapon system might reduce the bureaucratic enthusiasm or political backing for an extensive space monitoring system.

SIMPLIFICATIONS

Mitigating these complications are several offsetting factors which assist our capability for monitoring space arms control. First, although space is large, it is transparent and accessible to monitoring, and weaknesses in ground-based monitoring systems can be mitigated by putting those systems into space. Soviet satellites will be observable by U.S. national technical means. Confusion as to the true nature of a Soviet spacecraft may be mitigated by an agreement which will serve to reduce ambiguity of space operations. Furthermore, all ASAT-related activities start on the ground. Relevant ground sites, including launch facilities, can be observed by an extensive array of U.S. monitoring facilities; all launches of significant size from Soviet territory can now be detected. After all, although the Soviets have never publicly announced their existing ASAT tests, these tests have been detected and analyzed by the United States.

Second, if the Soviet Union attempts to conduct covert ASAT testing or development, it will need to monitor its own activity if it intends to obtain any data concerning how well its system performs. The Soviet requirement to recover data from or observe its activity in some way may also provide the United States with an opportunity to detect or intercept the transmission. The Soviet need to hide covert testing from the United States may narrow down the regions where the United States need concentrate its own verification effort.

Finally, the claim has been made that unattainably stringent levels of verification are needed for an ASAT treaty because U.S. targets are few and valuable and therefore vulnerable to even a small amount of cheating. This reasoning was thought by many participants to be not so much an argument against an ASAT treaty as it was a compelling reason for the United States to increase the survivability of its space systems. Rather than precluding arms control, the situation of having few but valuable satellites calls for having alternatives to them. "If the United States is truly and genuinely that dependent upon a few satellites, I'd just like to know what the hell DOD plans on doing about it, because in the absence of any ASAT arms control, the problems are only worse."

VERIFICATION PARTICULARS

The verification discussion was explicitly not intended to be an exhaustive analysis. Security considerations, in particular, prevented many highly relevant points from being studied in detail. However, like the other workshop sessions, the session on verification did serve to foster discussion on a range of topics.

One participant pointed out that ASAT treaties would ban, first of all, the act of destroying satellites, and that this aspect of any ASAT treaty is readily verifiable. Less clear was how detectable the capability to destroy a satellite or its ability to function would be.

Satellite failure can easily be detected. Although there was concern that the Soviets might be able to develop a system which could cause one or two U.S. satellites to fail in a manner mimicking an equipment malfunction, panelists noted that satellites presently have a lot of on-board "state-of-health" monitoring. These sensors can be augmented to determine whether a failure is due to an internal flaw or whether it has been externally induced. Satellites can have sensors to measure incident laser light, rises in temperature, or sudden accelerations, for example. A satellite's location or behavior might also indicate a cause for its failure, either hostile or benign. Therefore, the Soviets would not have high confidence that covert interference would remain undetected.

Central to the ASAT arms control debate is the level of residual or covert ASAT capability which could remain, or be developed covertly, after a treaty had been ratified. A panelist noted that capabilities associated with known ASAT launch sites and research and development facilities would be detectable. The detectability of other possible residual or covert activity was more controversial. One possible "worst-case" evaluation of ASAT capability which might be covertly developed or maintained under a test ban was attempted at the workshop. Again, no detailed assessment of the likelihood of these developments, or of the particular means the United States could employ to search for them, was undertaken. There was, however, a general feeling that nothing arose in that evaluation which would clearly permit covert development of a high-confidence, high-quality ASAT weapon under such a test ban, although some panelists did express strong reservations about the detectability of nuclear space mines and ground or air-based lasers. ASAT capability is categorized below by technology.

DIRECT INTERCEPTION

1) **Fully capable, dedicated, tested systems.**—Neither the United States nor the U.S.S.R. now has such a system. Developing one would require an extensive testing program. If such a proposed system were to be similar to the existing Soviet ASAT, its launches would be visible; orbiting vehicles would be noticed, especially maneuvering ones. If such a direct intercept system were to be similar to the U.S. miniature homing vehicle, its ascent could be seen, its telemetry could be detected, and its target could be seen. Suspicious rendezvous operations in space could be inquired about. Tests against points in space would eliminate any observation of the target, but there would be concomitant loss of confidence in the results of the test.

2) **Existing Soviet ASAT.**—Tests of the existing Soviet ASAT can be monitored. We possibly would not be assured that all ASAT interceptors had been destroyed pursuant to a ban, but we could with high reliability know if one had been tested. There will certainly not be high confidence that an ASAT interceptor would work reliably mated to a booster it has never been tested with. Even with no major design change, the confidence in and significance of any untested system is bound to degrade with time.

3) **Residual "baling-wire" direct intercept ASAT.**—One can never rule out the existence of some covert, improvised ASAT capability of this sort, but one can deny high confidence in such a system by preventing tests.

38-036 O - 84 - 87

4) Nuclear-armed ICBM or ABM missiles used as ASATs.—Testing nuclear warheads in space is risky, in terms of collateral damage to friendly systems; prohibited, under the limited test ban treaty; and easily detectable. (Testing warheads underground could be done with high confidence.) Nuclear ASAT capability cannot reasonably be prohibited since ICBMs and possibly ABMs will exist with or without an ASAT treaty. Workshop panelists felt that such systems did not present a significant ASAT threat except during nuclear war, in which case damage to satellites would be likely whether or not it had been intended. "The Soviets are bad, but they're not lunatics," said one panelist, "and I can just see no credibility whatsoever in the notion that they'd fling a nuclear weapon up into the heavens and crack it off. It would cost them a lot."

5) Non-nuclear ICBM or ABM used as ASATs.—With appropriate radar support, it is possible that the Soviet Galosh ABM could perform ASAT attacks with a non-nuclear charge. Galosh deployment and testing are permitted under the ABM treaty, but the location of the launchers and the consequent range of orbits at risk are limited by the ABM treaty and protocol. Testing of an ICBM or ABM in an ASAT profile would be prohibited under an ASAT test ban, would be differentiable from ABM tests, and would likely be detected.

"SPACE MINES"

In general, any satellite very close to another country's satellite is a priori suspicious. Any mine or weapon which would be effective from further away is a complex system which requires maneuvering or pointing and would therefore require testing. These tests would be detectable. Concerning close approach, however, panelists noted that under the regime presently existing on the high seas, opposing forces do have the right to make close approaches. Banning close approaches in space would require codification of principles not incorporated in present law. Such an agreement would be highly verifiable, and could be made even more so by putting potential target satellites in orbits "out in the middle of nowhere" where there would be no innocent reason for other satellites to be anywhere nearby at all.

1) Non-nuclear space mines.—These would have to get very close (on the order of 1 km) to their targets. There would be no innocent reason to have a satellite that close to another country's satellite, and such approaches could be easily detected.

2) Nuclear space mines.—The Outer Space Treaty of 1967 prohibits orbiting of "nuclear weapons, or any other kinds of weapons of mass destruction." Nuclear space mines are therefore presently prohibited. There are also significant inhibitions (collateral damage, breaking the nuclear threshold) against their use for ASAT (see "Nuclear-armed ICBM or ABM missiles" section above). At present, nuclear space mines can easily be built, tested underground, and deployed. However, actual emplacement of mines within a nuclear kill radius (100 to 200 km) of their targets, or of mines able to be maneuvered within that range, would likely be identified from tracking data. Inspector satellites that could detect nuclear weapons in space satellites were briefly discussed. However, they may not be technically feasible, and negotiating an agreement regulating their use might pose problems (see "Cooperative Verification Measures" section below).

3) Projectile-emitting.—Satellites carrying interceptors which could travel 100 kilometers or so to their targets could similarly be identified from tracking data; furthermore, projectile-emitting satellites would likely require extensive testing of their target acquisition and homing systems, and these tests would likely be detected.

DIRECTED ENERGY WEAPONS

1) Space-based directed energy.—Space-based directed energy weapons might best be considered space mines with kill radii of hundreds to thousands of kilometers since they are ef-

fectively instantaneously acting. Space-based, non-nuclear-pumped lasers would be quite large and may emit hydrogen fluoride or other gases. Their operation and testing would be observable. Nuclear-pumped directed energy weapons, like non-directed nuclear weapons, could not be tested covertly in space, and placing them into orbit is contrary to existing treaties. On-board nuclear weapons might be searched for (see discussion of inspection in "Cooperative Verification Measures" below).

2) **Air-based, ground-based, or pop-up directed energy.**—All such systems would require testing. Possible targets could in principle be monitored to see if they are being illuminated by strong lasers, are giving off gases, are being unexpectedly accelerated, or are emitting unusual signals. Air and ground-based systems may be detectable by national technical means; furthermore, they are increasingly less effective as the target altitude increases, since intensity drops off as the square of the distance between the weapon and the target. It is far easier to blind an optical sensor than to damage a satellite, requiring probably one millionth of the energy. Lasers capable of blinding sensors are easily available, so the capability of blinding sensors cannot be banned. However, the act of blinding a satellite would be readily detected: after all, "imaging satellites are only so particularly vulnerable when they are looking at you."

SPOOFING, JAMMING, OR OTHERWISE INTERFERING WITH THE OPERATION OF SYSTEMS USING SATELLITES

These categories would likely not be covered under an ASAT testing ban, since ensuring the absence of such capability would not be verifiable. Furthermore, the United States is not likely to negotiate away the capability to interfere with hostile satellites in these ways: "We would like to do that, we're very good at doing that, and we intend to do that in case of conflict."

COOPERATIVE VERIFICATION MEASURES

Some of the verification techniques discussed at the workshop would require, or would at least greatly benefit from, cooperative verification procedures between the United States and the U.S.S.R. Just one example would be verifying the absence of orbiting nuclear weapons, although such measures might be useful in many other cases as well.

If the capability for detecting nuclear weapons in orbit were felt to be required (note that the 1967 Outer Space Treaty forbidding them was ratified, and remains in force, in the absence of such explicit procedures), some sort of co-operative program would need to be established. One method mentioned at the workshop might involve a form of "on-orbit" inspection. In that example, all satellites would be required to withstand some level of neutron irradiation. On demand, suspect satellites would be subject to such irradiation from an orbiting inspector satellite. Emission of delayed neutrons from the target would reveal the presence of fissionable material. Alternatively, non-intrusive examination for fissionable material might be done on the launch pad.

There are several difficulties with inspection in orbit. In the case mentioned above, for example, it might be possible to conceal a nuclear warhead by shielding it appropriately. A more general problem with any "on-orbit" inspection is that the inspector satellite, requiring the capability to acquire, track, and rendezvous with a target satellite, would have and would regularly test all the attributes of an ASAT interceptor except for detonation of a warhead. Another problem with actively probing inspections in particular, noted a panelist, is that "if it's carrying an accelerator, one

might want to think about it"—such an inspector might indeed have ASAT potential in its own right. Perhaps limits on the size, approach velocity, or capability of inspector satellites could be established.

Appendix A

Survivability of Space Capability

All panelists agreed that survivable space capability is important to the United States with or without an ASAT treaty. An irreducible residual ASAT threat will remain under any treaty, making survivability measures essential. Without a treaty, of course, satellites will face dedicated ASAT systems in addition to residual capability, making survivability requirements that much more difficult.

"Survivable space capability" includes measures both to protect and to supplement satellites. U.S. satellites have been hardened against nuclear effects and are spaced so that not more than one at a time should be vulnerable to any one nuclear explosion. Protection includes hardening against radiation, hardening against system-generated electromagnetic pulse (high voltages induced within components by radiation from nuclear explosions), and hardening against other nuclear effects. There are additional protective measures which can and should be applied to satellites to guard against non-nuclear threats. Satellites can be made to evade direct-intercept ASATs or space mines by maneuvering or by interfering with (jamming or confusing) the ASAT's homing sensors. In the absence of an ASAT ban, satellites could conceivably also be given active defenses.

Another way to protect satellites is to proliferate them. Various functions can be distributed on a wide variety of satellites, and duplicate satellites can be orbited. These spares can be left silent until needed and they can be decoyed, making their detection and destruction more difficult. One of the most important motivations for distributing capability is to buy time—it will take much longer to destroy many satellites with shared functions than it will take to destroy any single satellite. Proliferated systems should be simpler and more basic than the full-fledged, highly sophisticated equipment now used in military satellites. Non-space assets such as ground stations would have to be proliferated as well, with the proviso again that the proliferated stations not be as complex as the main ground station.

Satellites can also be replaced by other systems. Today, satellites are used in support of strategic forces but they are not essential. Ground-based radars can be used for early warning. Nuclear detonation detection, besides being proliferated onto many small satellites, can be done for our own warheads by placing transmitters on them, if needed. Tactical theater support now done with satellites can be replaced with a variety of systems —remotely piloted aircraft, sounding rockets, balloons, and low-cost replacement satellites launched on cheap boosters or ICBMs or SLBMs. There are many alternatives to space for functions which are now carried out in space.

Appendix B

Compliance With the 1972 ABM Treaty

The Reagan Administration's recent public allegations of Soviet non-compliance with arms control agreements have drawn much attention. One of these allegations concerned construction of a radar in Siberia which was said to be almost certainly in violation of the 1972 ABM treaty. This radar was discussed at one point in the workshop, and portions of that discussion are described in this appendix.

THE SOVIET RADAR NEAR KRASNOYARSK

According to Articles III and IV of the ABM treaty, ABM radars may be located only at agreed ABM sites or test ranges. Article VI notes that early warning radars may not be constructed except on the periphery of the country and looking outward. Agreed Statement F states that phased-array (electronically steered) radars greater than a specified size may not be deployed except as permitted by Articles III, IV, and VI. It goes on to exempt radars used "for the purposes of tracking objects in outer space or for use as national technical means."

The Soviets are constructing a phased-array radar of greater than the specified size near Krasnoyarsk in central Siberia. The location is not near the periphery of the country and it is not oriented outwards. If it is indeed an early warning or ABM battle management radar, the Soviets are in violation of the ABM treaty. The Soviets claim that the radar is allowable under the exemption in Statement F. Since it is geographically poorly sited to be effective for intelligence (national technical means) purposes, it would have to be a space track radar to be permitted under the treaty.

The administration has charged that this radar "almost certainly" violates the ABM treaty. Others find the issue somewhat less clear. The radar "sort of looks like a duck, and it walks a little bit like a duck, but it doesn't look quite like all the other ducks," in the words of one panelist. "The Soviets say, 'Oh, don't worry. It's not a duck. Notice there are some differences between it and other ducks, and when you hear it later, you'll find out it barks. It doesn't quack.' "

According to a panelist, the signal from a space track radar (a "dog") would be quite different from that of a radar used for ABM battle management (a "duck"). Therefore, the question will presumably be resolved when the radar becomes operational. However, some panelists were not willing to wait that long to find out, and they thought that the administration's announcement was proper. "You can't expect me to look at something that looks like a duck and walks like a duck and tell me it's a dog and I'm supposed to take it on faith. . . . You've got to provide more help than that." They felt that the Soviets were obligated to be more forthcoming about the radar than they had been within diplomatic channels, and that the public announcement served notice that the United States feels the issue has not adequately been resolved. Other panelists felt that existing channels were the appropriate forum and that the public announcement did not serve any constructive purpose.

Some panelists were generally skeptical as to whether the radar is in fact in violation of the ABM treaty. The utility of having such a flagrantly illegal early-warning radar, if it is one, was not felt to be sufficient incentive for the Soviets to unilaterally abrogate the ABM treaty. Others, including some who had access to intelligence data, had little doubt that the radar is indeed optimized for the ABM role. The alternative to being an illegal ABM radar is for the radar to be for tracking satellites, indicating a buildup of the Soviet space monitoring capability and being at least suggestive of an extension of their ASAT program.

BREAKOUT FROM AND LOOPHOLES IN THE ABM TREATY

The ABM treaty is under a great deal of pressure. In the United States, no ongoing research, development, or deployment contradicts treaty provisions. However, deployment of ballistic missile defense beyond the permitted single site would violate the ABM treaty, as would development, testing, or deployment of any ABM systems or components other than fixed, land-based ones. A panelist estimated that at the time of President Reagan's March 23, 1983 "Star Wars" speech, U.S. research into ground-based BMD components was about three years away from the point at which continuation could have run up against the ABM treaty. In light of the March 23 speech and

ensuing developments, this estimate may be lengthened to about a decade because more futuristic BMD technologies, which are highly immature, presumably will be emphasized at the expense of the older, more developed systems which were closer to deployment.

The Soviets, according to articles in *Aviation Week and Space Technology* referred to by workshop participants, are building defenses against tactical ballistic missiles. Since the ABM treaty prohibits defenses only against **strategic** missiles, anti-tactical ballistic missile (ATBM) systems are not covered and are therefore permitted. Anti-tactical ballistic missiles were not included in the ABM treaty at United States insistence in order to protect SAM-D, a surface-to-air missile then under development which was intended to have some capability against short-range tactical ballistic missiles as well as against aircraft. However, according to a panelist, as SAM-D developed (changing its name to 'Patriot'), "it lost not only its capability against missiles, but it lost much of its anti-aircraft capability" as well. At the same time, "the Soviets have essentially designed and deployed the 'SAM-D-ski', which looks a lot like what we were trying to protect."

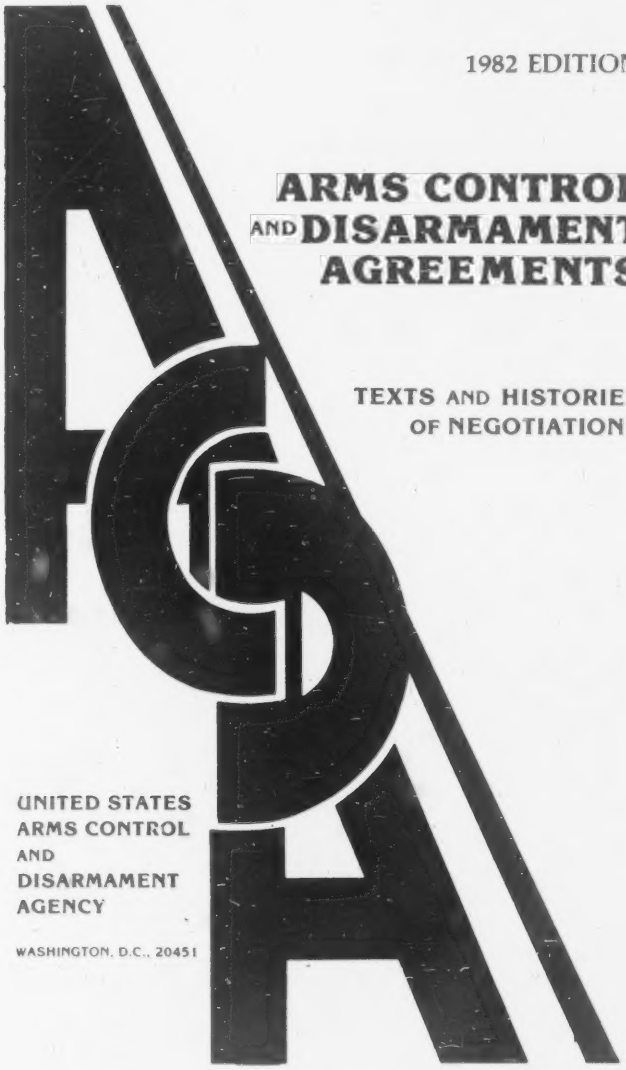
ATBM systems, and their impact on the continuing viability of the ABM treaty, were a source of considerable concern to many panelists. A panelist felt that "if things are deployed under the rubric of anti-tactical ballistic missiles, they can or will have an impact on the penetrability of our SLBMs and the French deterrent system and the British deterrent system, and the whole ball of wax can unravel." The U.S. deployment of Pershing II missiles in Europe could stimulate a particularly troubling Soviet ATBM deployment. 'The United States has no excuse for deploying anti-tactical ballistic missiles in its homeland," pointed out a participant, "but the Soviet Union does—and we're giving them a better one. We are now deploying an offensive system that says, 'Hey, you know those ATBMs? Come on, bring them out, there's a legitimate use for them now.' "

Panelists did note that, even if the Soviets should deploy extensive ATBM systems, it need not change the strategic balance. "We know how to deal with them," said one. "It requires penetration aids. We know how to do that." These aids are not presently deployed in the strategic inventory, which "we ought to do something about," but the United States is not in imminent danger of being effectively disarmed.

Another cause for concern is the continued miniaturization of components. Those who worry about possible scenarios in which the Soviet Union builds and stockpiles components in preparation for rapid breakout from the ABM treaty are worrying more now because small radars can have enough capability to fulfill some ABM roles. Even so, small radars cannot do so in the absence of large phased-array battle management radars. Since ABM battle management radars and space track radars share at least some characteristics, panelists felt that a radar clause might be required in an ASAT agreement to prevent circumvention of the ABM treaty restrictions on radars.

Appendix C

ABM Treaty and Related Documents



Treaty Between the United States of America and the Union of Soviet Socialist Republics on the Limitation of Anti-Ballistic Missile Systems

Signed at Moscow May 26, 1972
Ratification advised by U.S. Senate August 3, 1972
Ratified by U.S. President September 30, 1972
Proclaimed by U.S. President October 3, 1972
Instruments of ratification exchanged October 3, 1972
Entered into force October 3, 1972

The United States of America and the Union of Soviet Socialist Republics, hereinafter referred to as the Parties,

Proceeding from the premise that nuclear war would have devastating consequences for all mankind,

Considering that effective measures to limit anti-ballistic missile systems would be a substantial factor in curbing the race in strategic offensive arms and would lead to a decrease in the risk of outbreak of war involving nuclear weapons,

Proceeding from the premise that the limitation of anti-ballistic missile systems, as well as certain agreed measures with respect to the limitation of strategic offensive arms, would contribute to the creation of more favorable conditions for further negotiations on limiting strategic arms,

Mindful of their obligations under Article VI of the Treaty on the Non-Proliferation of Nuclear Weapons,

Declaring their intention to achieve at the earliest possible date the cessation of the nuclear arms race and to take effective measures toward reductions in strategic arms, nuclear disarmament, and general and complete disarmament,

Desiring to contribute to the relaxation of international tension and the strengthening of trust between States,

Have agreed as follows:

Article I

1. Each party undertakes to limit anti-ballistic missile (ABM) systems and to adopt other measures in accordance with the provisions of this Treaty.

2. Each Party undertakes not to deploy ABM systems for a defense of the territory of its country and not to provide a base for such a defense, and not to deploy ABM systems for defense of an individual region except as provided for in Article III of this Treaty.

Article II

1. For the purpose of this Treaty an ABM system is a system to counter strategic ballistic missiles or their elements in flight trajectory, currently consisting of:

(a) ABM interceptor missiles, which are interceptor missiles constructed and deployed for an ABM role, or of a type tested in an ABM mode,

(b) ABM launchers, which are launchers constructed and deployed for launching ABM interceptor missiles; and

(c) ABM radars, which are radars constructed and deployed for an ABM role, or of a type tested in an ABM mode.

2. The ABM system components listed in paragraph 1 of this Article include those which are:

(a) operational;
(b) under construction;
(c) undergoing testing;
(d) undergoing overhaul, repair or conversion; or
(e) mothballed.

Article III

Each Party undertakes not to deploy ABM systems or their components except that:

(a) within one ABM system deployment area having a radius of one hundred and fifty kilometers and centered on the Party's national capital, a Party may deploy: (1) no more than one hundred ABM launchers and no more than one hundred ABM interceptor missiles at launch sites, and (2) ABM radars within no more than six ABM radar complexes, the area of each complex being circular and having a diameter of no more than three kilometers; and

(b) within one ABM system deployment area having a radius of one hundred and fifty kilometers and containing ICBM silo launchers, a Party may deploy: (1) no more than one hundred ABM launchers and no more than one hundred ABM interceptor missiles at launch sites, (2) two large phased-array ABM radars comparable in potential to corresponding ABM radars operational or under construction on the date of signature of the Treaty in an ABM system deployment area containing ICBM silo launchers, and (3) no more than eighteen ABM radars each having a potential less than the potential of the smaller of the above-mentioned two large phased-array ABM radars.

Article IV

The limitations provided for in Article III shall not apply to ABM systems or their components used for development or testing, and located within current or additionally agreed test ranges. Each Party may have no more than a total of fifteen ABM launchers at test ranges.

Article V

1. Each Party undertakes not to develop, test, or deploy ABM systems or components which are sea-based, air-based, space-based, or mobile land-based.

2. Each Party undertakes not to develop, test, or deploy ABM launchers for launching more than one ABM interceptor missile at a time from each launcher, not to modify deployed launchers to provide them with such a capability, not to develop, test, or deploy automatic or semi-automatic or other similar systems for rapid reload of ABM launchers.

Article VI

To enhance assurance of the effectiveness of the limitations on ABM systems and their components provided by the Treaty, each Party undertakes:

(a) not to give missiles, launchers, or radars, other than ABM interceptor missiles, ABM launchers, or ABM radars, capabilities to counter strategic ballistic missiles or their elements in flight trajectory, and not to test them in an ABM mode; and

(b) not to deploy in the future radars for early warning of strategic ballistic missile attack except at locations along the periphery of its national territory and oriented outward.

Article VII

Subject to the provisions of this Treaty, modernization and replacement of ABM systems or their components may be carried out.

Article VIII

ABM systems or their components in excess of the numbers or outside the areas specified in this Treaty, as well as ABM systems or their components prohibited by this Treaty, shall be destroyed or dismantled under agreed procedures within the shortest possible agreed period of time.

Article IX

To assure the viability and effectiveness of this Treaty, each Party undertakes not to transfer to other States, and not to deploy outside its national territory, ABM systems or their components limited by this Treaty.

Article X

Each Party undertakes not to assume any international obligations which would conflict with this Treaty.

Article XI

The Parties undertake to continue active negotiations for limitations on strategic offensive arms.

Article XII

1. For the purpose of providing assurance of compliance with the provisions of this Treaty, each Party shall use national technical means of verification at its disposal in a manner consistent with generally recognized principles of international law.

2. Each Party undertakes not to interfere with the national technical means of verification of the other Party operating in accordance with paragraph 1 of this Article.

3. Each Party undertakes not to use deliberate concealment measures which impede verification by national technical means of compliance with the provisions of this Treaty. This obligation shall not require changes in current construction, assembly, conversion, or overhaul practices.

Article XIII

1. To promote the objectives and implementation of the provisions of this Treaty, the Parties shall establish promptly a Standing Consultative Commission, within the framework of which they will:

(a) consider questions concerning compliance with the obligations assumed and related situations which may be considered ambiguous;

(b) provide on a voluntary basis such information as either Party considers necessary to assure confidence in compliance with the obligations assumed;

(c) consider questions involving unintended interference with national technical means of verification;

(d) consider possible changes in the strategic situation which have a bearing on the provisions of this Treaty;

(e) agree upon procedures and dates for destruction or dismantling of ABM systems or their components in cases provided for by the provisions of this Treaty;

(f) consider, as appropriate, possible proposals for further increasing the viability of this Treaty, including proposals for amendments in accordance with the provisions of this Treaty;

(g) consider, as appropriate, proposals for further measures aimed at limiting strategic arms.

2. The Parties through consultation shall establish, and may amend as appropriate, Regulations for the Standing Consultative Commission governing procedures, composition and other relevant matters.

Article XIV

1. Each Party may propose amendments to this Treaty. Agreed amendments shall enter into force in accordance with the procedures governing the entry into force of this Treaty.

2. Five years after entry into force of this Treaty, and at five-year intervals thereafter, the Parties shall together conduct a review of this Treaty.

Article XV

1. This Treaty shall be of unlimited duration.

2. Each Party shall, in exercising its national sovereignty, have the right to withdraw from this Treaty if it decides that extraordinary events related to the subject matter of this Treaty have jeopardized its supreme interests. It shall give notice of its decision to the other Party six months prior to withdrawal from the Treaty. Such notice shall include a statement of the extraordinary events the notifying Party regards as having jeopardized its supreme interests.

Article XVI

1. This Treaty shall be subject to ratification in accordance with the constitutional procedures of each Party. The Treaty shall enter into force on the day of the exchange of instruments of ratification.

2. This Treaty shall be registered pursuant to Article 102 of the Charter of the United Nations.

DONE at Moscow on May 26, 1972, in two copies, each in the English and Russian languages, both texts being equally authentic.

FOR THE UNITED STATES OF AMERICA	**FOR THE UNION OF SOVIET SOCIALIST REPUBLICS**
RICHARD NIXON	**L. I. BREZHNEV**
President of the United States of America	*General Secretary of the Central Committee of the CPSU*

Agreed Statements, Common Understandings, and Unilateral Statements Regarding the Treaty Between the United States of America and the Union of Soviet Socialist Republics on the Limitation of Anti-Ballistic Missiles

1. Agreed Statements

The document set forth below was agreed upon and initialed by the Heads of the Delegations on May 26, 1972 (letter designations added).

AGREED STATEMENTS REGARDING THE TREATY BETWEEN THE UNITED STATES OF AMERICA AND THE UNION OF SOVIET SOCIALIST REPUBLICS ON THE LIMITATION OF ANTI-BALLISTIC MISSILE SYTEMS

[A]

The Parties understand that, in addition to the ABM radars which may be deployed in accordance with subparagraph (a) of Article III of the Treaty, those non-phased-array ABM radars operational on the date of signature of the Treaty within the ABM system deployment area for defense of the national capital may be retained.

[B]

The Parties understand that the potential (the product of mean emitted power in watts and antenna area in square meters) of the smaller of the two large phased-array ABM radars referred to in subparagraph (b) of Article III of the Treaty is considered for purposes of the Treaty to be three million.

[C]

The Parties understand that the center of the ABM system deployment area centered on the national capital and the center of the ABM system deployment area containing ICBM silo launchers for each Party shall be separated by no less than thirteen hundred kilometers.

[D]

In order to insure fulfillment of the obligation not to deploy ABM systems and their components except as provided in Article III of the Treaty, the Parties agree that in the event ABM systems based on other physical principles and including components capable of substituting for ABM interceptor missiles, ABM launchers, or ABM radars are created in the future, specific limitations on such systems and their components would be subject to discussion in accordance with Article XIII and agreement in accordance with Article XIV of the Treaty.

[E]

The Parties understand that Article V of the Treaty includes obligations not to develop, test or deploy ABM interceptor missiles for the delivery by each ABM interceptor missile of more than one independently guided warhead.

[F]

The Parties agree not to deploy phased-array radars having a potential (the product of mean emitted power in watts and antenna area in square meters) exceeding three million, except as provided for in Articles III, IV and VI of the Treaty, or except for the purposes of tracking objects in outer space or for use as national technical means of verification.

[G]

The Parties understand that Article IX of the Treaty includes the obligation of the US and the USSR not to provide to other States technical descriptions or blue prints specially worked out for the construction of ABM systems and their components limited by the Treaty.

2. Common Understandings

Common understanding of the Parties on the following matters was reached during the negotiations.

A. Location of ICBM Defenses

The U.S. Delegation made the following statement on May 26, 1972:

Article III of the ABM Treaty provides for each side one ABM system deployment area centered on its national capital and one ABM system deployment area containing ICBM silo launchers. The two sides have registered agreement on the following statement: "The Parties understand that the center of the ABM system deployment area centered on the national capital and the center of the ABM system deployment area containing ICBM silo launchers for each Party shall be separated by no less than thirteen hundred kilometers." In this connection, the U.S. side notes that its ABM system deployment area for defense of ICBM silo launchers, located west of the Mississippi River, will be centered in the Grand Forks ICBM silo launcher deployment area. (See Agreed Statement [C].)

B. ABM Test Ranges

The U.S. Delegation made the following statement on April 26, 1972:

Article IV of the ABM Treaty provides that "the limitations provided for in Article III shall not apply to ABM systems or their components used for development or testing, and located within current or additionally agreed test ranges." We believe it would be useful to assure that there is no misunderstanding as to current ABM test ranges. It is our understanding that ABM test ranges encompass the area within which ABM components are located for test purposes. The current U.S. ABM test ranges are at White Sands, New Mexico, and at Kwajalein Atoll, and the current Soviet ABM test range is near Sary Shagan in Kazakhstan. We consider that non-phased array radars of types used for range safety or instrumentation purposes may be located outside of ABM test ranges. We interpret the reference in Article IV to "additionally agreed test

ranges" to mean that ABM components will not be located at any other test ranges without prior agreement between our Governments that there will be such additional ABM test ranges.

On May 5, 1972, the Soviet Delegation stated that there was a common understanding on what ABM test ranges were, that the use of the types of non-ABM radars for range safety or instrumentation was not limited under the Treaty, that the reference in Article IV to "additionally agreed" test ranges was sufficiently clear, and that national means permitted identifying current test ranges.

C. Mobile ABM Systems

On January 29, 1972, the U.S. Delegation made the following statement:

Article V(1) of the Joint Draft Text of the ABM Treaty includes an undertaking not to develop, test, or deploy mobile land-based ABM systems and their components. On May 5, 1971, the U.S. side indicated that, in its view, a prohibition on deployment of mobile ABM systems and components would rule out the deployment of ABM launchers and radars which were not permanent fixed types. At that time, we asked for the Soviet view of this interpretation. Does the Soviet side agree with the U.S. side's interpretation put forward on May 5, 1971?

On April 13, 1972, the Soviet Delegation said there is a general common understanding on this matter.

D. Standing Consultative Commission

Ambassador Smith made the following statement on May 22, 1972:

The United States proposes that the sides agree that, with regard to initial implementation of the ABM Treaty's Article XIII on the Standing Consultative Commission (SCC) and of the consultation Articles to the Interim Agreement on offensive arms and the Accidents Agreement,[1] agreement establishing the SCC will be worked out early in the follow-on SALT negotiations; until that is completed, the following arrangements will prevail: when SALT is in session, any consultation desired by either side under these Articles can be carried out by the two SALT Delegations; when SALT is not in session, *ad hoc* arrangements for any desired consultations under these Articles may be made through diplomatic channels.

Minister Semenov replied that, on an *ad referendum* basis, he could agree that the U.S. statement corresponded to the Soviet understanding.

E. Standstill

On May 6, 1972, Minister Semenov made the following statement:

In an effort to accommodate the wishes of the U.S. side, the Soviet Delegation is prepared to proceed on the basis that the two sides will in fact observe the obligations of both the Interim Agreement and the ABM Treaty beginning from the date of signature of these two documents.

In reply, the U.S. Delegation made the following statement on May 20, 1972:

---

[1]See Article 7 of Agreement to Reduce the Risk of Outbreak of Nuclear War Between the United States of America and the Union of Soviet Socialist Republics, signed Sept. 30, 1971.

The U.S. agrees in principle with the Soviet statement made on May 6 concerning observance of obligations beginning from date of signature but we would like to make clear our understanding that this means that, pending ratification and acceptance, neither side would take any action prohibited by the agreements after they had entered into force. This understanding would continue to apply in the absence of notification by either signatory of its intention not to proceed with ratification or approval.

The Soviet Delegation indicated agreement with the U.S. statement.

3. Unilateral Statements

The following noteworthy unilateral statements were made during the negotiations by the United States Delegation:

A. Withdrawal from the ABM Treaty

On May 9, 1972, Ambassador Smith made the following statement:

The U.S. Delegation has stressed the importance the U.S. Government attaches to achieving agreement on more complete limitations on strategic offensive arms, following agreement on an ABM Treaty and on an Interim Agreement on certain measures with respect to the limitation of strategic offensive arms. The U.S. Delegation believes that an objective of the follow-on negotiations should be to constrain and reduce on a long-term basis threats to the survivability of our respective strategic retaliatory forces. The USSR Delegation has also indicated that the objectives of SALT would remain unfulfilled without the achievement of an agreement providing for more complete limitations on strategic offensive arms. Both sides recognize that the initial agreements would be steps toward the achievement of more complete limitations on strategic arms. If an agreement providing for more complete strategic offensive arms limitations were not achieved within five years, U.S. supreme interests could be jeopardized. Should that occur, it would constitute a basis for withdrawal from the ABM Treaty. The U.S. does not wish to see such a situation occur, nor do we believe that the USSR does. It is because we wish to prevent such a situation that we emphasize the importance the U.S. Government attaches to achievement of more complete limitations on strategic offensive arms. The U.S. Executive will inform the Congress, in connection with Congressional consideration of the ABM Treaty and the Interim Agreement, of this statement of the U.S. position.

B. Tested in ABM Mode

On April 7, 1972, the U.S. Delegation made the following statement:

Article II of the Joint Text Draft uses the term "tested in an ABM mode," in defining ABM components, and Article VI includes certain obligations concerning such testing. We believe that the sides should have a common understanding of this phrase. First, we would note that the testing provisions of the ABM Treaty are intended to apply to testing which occurs after the date of signature of the Treaty, and not to any testing which may have occurred in the past. Next, we would amplify the remarks we have made on this subject during the previous Helsinki phase by setting forth the objectives which govern the U.S. view on the subject, namely, while prohibiting testing of non-ABM components for ABM purposes; not to prevent testing of ABM components, and not to prevent testing of non-ABM components for

non-ABM purposes. To clarify our interpretation of "tested in an ABM mode," we note that we would consider a launcher, missile or radar to be "tested in an ABM mode" if, for example, any of the following events occur: (1) a launcher is used to launch an ABM interceptor missile, (2) an interceptor missile is flight tested against a target vehicle which has a flight trajectory with characteristics of a strategic ballistic missile flight trajectory, or is flight tested in conjunction with the test of an ABM interceptor missile or an ABM radar at the same test range, or is flight tested to an altitude inconsistent with interception of targets against which air defenses are deployed, (3) a radar makes measurements on a cooperative target vehicle of the kind referred to in item (2) above during the reentry portion of its trajectory or makes measurements in conjunction with the test of an ABM interceptor missile or an ABM radar at the same test range. Radars used for purposes such as range safety or instrumentation would be exempt from application of these criteria.

C. No-Transfer Article of ABM Treaty

On April 18, 1972, the U.S. Delegation made the following statement:

In regard to this Article [IX], I have a brief and I believe self-explanatory statement to make. The U.S. side wishes to make clear that the provisions of this Article do not set a precedent for whatever provision may be considered for a Treaty on Limiting Strategic Offensive Arms. The question of transfer of strategic offensive arms is a far more complex issue, which may require a different solution.

D. No Increase in Defense of Early Warning Radars

On July 28, 1970, the U.S. Delegation made the following statement:

Since Hen House radars [Soviet ballistic missile early warning radars] can detect and track ballistic missile warheads at great distances, they have a significant ABM potential. Accordingly, the U.S. would regard any increase in the defenses of such radars by surface-to-air missiles as inconsistent with an agreement.

Protocol to the Treaty Between the United States of America and the Union of Soviet Socialist Republics on the Limitation of Anti-Ballistic Missile Systems

Signed at Moscow July 3, 1974
Ratification advised by U.S. Senate November 10, 1975
Ratified by U.S. President March 19, 1976
Instruments of ratification exchanged May 24, 1976
Proclaimed by U.S. President July 6, 1976
Entered into force May 24, 1976

The United States of America and the Union of Soviet Socialist Republics, hereinafter referred to as the Parties,

Proceeding from the Basic Principles of Relations between the United States of America and the Union of Soviet Socialist Republics signed on May 29, 1972,

Desiring to further the objectives of the Treaty between the United States of America and the Union of Soviet Socialist Republics on the Limitation of Anti-Ballistic Missile Systems signed on May 26, 1972, hereinafter referred to as the Treaty,

Reaffirming their conviction that the adoption of further measures for the limitation of strategic arms would contribute to strengthening international peace and security,

Proceeding from the premise that further limitation of anti-ballistic missile systems will create more favorable conditions for the completion of work on a permanent agreement on more complete measures for the limitation of strategic offensive arms,

Have agreed as follows:

Article I

1. Each Party shall be limited at any one time to a single area out of the two provided in Article III of the Treaty for deployment of anti-ballistic missile (ABM) systems or their components and accordingly shall not exercise its right to deploy an ABM system or its components in the second of the two ABM system deployment areas permitted by Article III of the Treaty, except as an exchange of one permitted area for the other in accordance with Article II of this Protocol.

2. Accordingly, except as permitted by Article II of this Protocol, the United States of America shall not deploy an ABM system or its components in the area centered on its capital, as permitted by Article III(a) of the Treaty, and the Soviet Union shall not deploy an ABM system or its components in the deployment area of intercontinental ballistic missile (ICBM) silo launchers as permitted by Article III(b) of the Treaty.

Article II

1. Each Party shall have the right to dismantle or destroy its ABM system and the components thereof in the area where they are presently deployed and to deploy an ABM system or its components in the alternative area permitted by Article III of the Treaty, provided that prior to initiation of construction, notification is given in accord

with the procedure agreed to in the Standing Consultative Commission, during the year beginning October 3, 1977 and ending October 2, 1978, or during any year which commences at five year intervals thereafter, those being the years for periodic review of the Treaty, as provided in Article XIV of the Treaty. This right may be exercised only once.

2. Accordingly, in the event of such notice, the United States would have the right to dismantle or destroy the ABM system and its components in the deployment area of ICBM silo launchers and to deploy an ABM system or its components in an area centered on its capital, as permitted by Article III(a) of the Treaty, and the Soviet Union would have the right to dismantle or destroy the ABM system and its components in the area centered on its capital and to deploy an ABM system or its components in an area containing ICBM silo launchers, as permitted by Article III(b) of the Treaty.

3. Dismantling or destruction and deployment of ABM systems or their components and the notification thereof shall be carried out in accordance with Article VIII of the ABM Treaty and procedures agreed to in the Standing Consultative Commission.

Article III

The rights and obligations established by the Treaty remain in force and shall be complied with by the Parties except to the extent modified by this Protocol. In particular, the deployment of an ABM system or its components within the area selected shall remain limited by the levels and other requirements established by the Treaty.

Article IV

This Protocol shall be subject to ratification in accordance with the constitutional procedures of each Party. It shall enter into force on the day of the exchange of instruments of ratification and shall thereafter be considered an integral part of the Treaty.

DONE at Moscow on July 3, 1974, in duplicate, in the English and Russian languages, both texts being equally authentic.

For the United States of America:

RICHARD NIXON

President of the United States of America

For the Union of Soviet Socialist Republics:

L. I. BREZHNEV

General Secretary of the Central Committee of the CPSU

Office of Technology Assessment

The Office of Technology Assessment (OTA) was created in 1972 as an analytical arm of Congress. OTA's basic function is to help legislative policymakers anticipate and plan for the consequences of technological changes and to examine the many ways, expected and unexpected, in which technology affects people's lives. The assessment of technology calls for exploration of the physical, biological, economic, social, and political impacts that can result from applications of scientific knowledge. OTA provides Congress with independent and timely information about the potential effects—both beneficial and harmful—of technological applications.

Requests for studies are made by chairmen of standing committees of the House of Representatives or Senate; by the Technology Assessment Board, the governing body of OTA; or by the Director of OTA in consultation with the Board.

The Technology Assessment Board is composed of six members of the House, six members of the Senate, and the OTA Director, who is a nonvoting member.

OTA has studies under way in nine program areas: energy and materials; industry, technology, and employment; international security and commerce; biological applications; food and renewable resources; health; communication and information technologies; oceans and environment; and science, transportation, and innovation.

OTA Publishing Staff: John Bergling, Kathie S. Boss, Debra M. Datcher, Joe Henson, John C. Holmes

As the U.S. Administration pushes for lasers or particle beams as a defense against attacking nuclear missiles, the question is, could such a system be effective and reliable?

Lasers for missile defense

In late March President Reagan called upon scientists "to turn their great talents to the cause of mankind and world peace: to give us the means of rendering . . . nuclear weapons impotent and obsolete." The President had in mind not the formulation of new arms control agreements with the Soviet Union, nor the invention of novel ways of verifying compliance with such agreements. He was considering instead the development of high energy laser beams and other weapons for launching the military into space. He was asking scientists to help create a new generation of strategic weapons.

The prospect of the militarization of space has met with little opposition, largely because lasers are advertised not as a mere weapon, but as an "anti-weapon weapon." Lasers, it is claimed, would protect the people of this country from a nuclear attack; they would put an end to the nuclear arms race and enable the United States to live in peace under a shield of light. The types of space lasers being discussed in the Senate and in industry, oddly enough, are only capable of shooting down a few satellites and perhaps a small fraction of attacking Soviet missiles. But, the argument goes, an anti-satellite laser would be a first step to a laser defense against missiles in 30 or 40 years.

The idea that lasers in space could defeat a nuclear attack is, however, fatally flawed. It is unlikely that any system of lasers, no matter how comprehensive, could destroy missiles with sufficient reliability to be regarded as the main component of a defense against nuclear attack. And even if it could, missiles are not the only means of delivering nuclear weapons. Moreover, putting in orbit a system of lasers big enough to begin to protect civilian targets from missile attack would require tremendous effort, most likely larger than any military project yet undertaken. Finally, the deployment of even a small laser system – despite its ineffectiveness as a defense – would create profound instabilities in the strategic balance between the United States and the Soviet Union.

A laser anti-ballistic missile (ABM) system would have several components: one or more high-energy lasers, mirrors to point and focus the laser beam, sensors to detect and locate missiles in flight, and a command system for firing the lasers. Advocates of a laser ABM system envision a number of "battle stations" orbiting the Earth and providing continuous coverage of its surface. Since it would be in space, the laser beam would not be absorbed by the Earth's atmosphere. Whenever the launch of a hostile missile was detected, the beam would be directed precisely in the direction of the missile. The shooting would occur during the "boost phase" of the missile's flight, which lasts for the first 250 seconds or so when the rocket is under power. The missile would be targeted during the boost phase for three technical reasons: During this phase, the target is relatively "soft," can be tracked by following the rocket's flame, and all of the MIRVed warheads can be destroyed at once.

The designer of a system of lasers for defense against ballistic missiles is faced with three fundamental constraints:

- Laser light, like any other light, beyond a certain distance decreases in intensity of power as the square of the distance from the source. Even in the vacuum of space, the range of any laser weapon is limited by this basic physical principle.
- The lower the orbit and range of a laser, the smaller the area of the laser's coverage. While three satellites in geosynchronous orbit of 30,000 kilometers could cover the Earth's whole surface, more than 200 would be needed if the lasers had a range of 1,000 kilometers. Because satellites in low orbit cannot hover over one spot, in order to cover all of the Soviet Union it is necessary to cover virtually the whole of the Earth's surface.
- For an effective defense, the laser system would have to be designed to deal with the worst case situation – the Soviets launching all of their approximately 2,000 missiles in a short time. A sufficient number of lasers would need to be in position over the Soviet Union at all times to be capable of shooting down the missile force. Thus, the number of lasers needed for an effective ABM becomes very large.

Contrary to popular notions, laser weapons do not vaporize the target. Instead, the energy in a laser beam weakens the skin of the missile, causing it to destroy itself by its own internal stresses. Missiles have a certain "hardness," which corresponds to the amount of energy per square centimeter which the laser must deliver to destroy the missile.

Although the details of laser systems now under consideration by the military are classified, it is possible, using the principles outlined above, to determine the size of a laser system needed to defend against a barrage launching of all Soviet missiles. We have done so for the two types of lasers most discussed in the Senate as candidates for a laser ABM. The "small" laser is a five-megawatt hydrogen fluoride laser with optics four meters in diameter. The "large" laser is a 10-megawatt hydrogen fluo-

Daniel Kaplan is a scientist with Battelle Pacific Northwest Laboratories in Washington, D.C. (20036). He was formerly associated with the Federation of American Scientists.

ride laser with 10-meter optics. Both are huge compared with present high-energy lasers, and the optics are not comparable in size and precision to any high-power mirror that has yet been built. (See accompanying table for a range of missile hardness.)

Number of Lasers Needed for Defense[a]

Laser type	*Missile hardness (joules per square centimers)*	*Number of lasers required*
small	soft (300)	760
	medium (2,000)	4,700
	hard (20,000)	Hard missiles cannot be destroyed by small lasers.
large	soft (300)	55
	medium (2,000)	400
	hard (20,000)	4,000

[a]Theoretical minimum number of lasers needed to defend against a concerted launching of 2,000 Soviet missiles.[1]

It has been estimated that each laser weapon would weigh 100 tons. If this is true, as many as 14,000 launches of the space shuttle would be required to place the lasers in orbit, and more launches would be needed to maintain them. Currently, fewer than 400 launches of the space shuttle are planned through 1992. The National Aeronautics and Space Administration (NASA) estimates that a substantial increase in the number of launches would cause considerable harm to the ozone layer.

This is not the whole story, however. Only about four percent of the laser satellites would be over the Soviet Union at any one time. It is these four percent that would shoot at Soviet missiles in the event of an attack; the other 96 percent would be out of range. Advanced military equipment is in service typically around 60 percent of the time. Assuming that the lasers would be 80 percent reliable—even though they would be more complicated than any of today's military equipment—there is still a good chance that some of those few satellites over the Soviet Union would not be working. In order to protect against a hole in the defense, it would be necessary at least to double the number of satellites in orbit.

Such a huge system of lasers is certainly not practicable. And in any case, even a system of this magnitude probably could not prevent tens or hundreds of MIRVed missiles from getting through, allowing hundreds or thousands of warheads to reach U.S. cities. To see why this is so, assume that a "perfect" defense system could be deployed—perhaps a laser system with a backup "conventional" ABM. In order to determine with any certainty that the system is, say, 98 percent effective, hundreds of missiles would have to be tested against it, an expensive and perhaps dangerous operation. And even if testing of this magnitude took place, it would not be under the full range of war conditions. Nor could tests take into consideration unknown Soviet advances in hardening missiles or disabling the laser system. Thus, however perfect the system appears on the drawing board, it is unlikely to be considered more than 98 percent effective. If the Soviets deployed no more missiles than allowed by SALT II, more than 400 warheads could still get through such a defense, enough to inflict huge damage.

Despite speculation that lasers could shift the emphasis of nuclear strategy from deterrence to defense, it is unlikely that a laser ABM could do more than supplement a deterrent force. A laser defense probably would be little more than another element in the sort of nuclear balance of terror that exists today. Not only is it likely that missiles can penetrate a laser defense; a defense against nuclear attack would also be incomplete without some means of protecting against low-flying bombers, cruise missiles and other low-altitude delivery systems. The atmosphere absorbs, scatters and defocuses laser light, affording a natural protection against lasers to weapons operating at low altitudes. Unless a means of countering these effects is developed, a laser ABM would be only a partial defense, even if it were completely effective against missiles.

In addition to using cruise missiles and bombers, it is possible to counter laser weapons directly. For instance, a laser could be destroyed—before or after it became operational—by exploding a nuclear bomb nearby in space. Or, space mines could be used, with satellites carrying explosive charges stationed nearby to destroy the lasers before they were functional. Some have claimed that by a combination of armoring the laser and using it to shoot down anything that threatens it, a laser could be protected against attack. However, this does not seem to be practicable. One reason is that a laser weapon must have large optics, which are necessarily susceptible to damage. An effective way of disabling a laser, therefore, would be to shoot at its optics with a wire mesh, sand, or ball bearings travelling at high speed. Because the projectiles would be small, and not contain sensitive explosives or guidance equipment, the laser would have to vaporize them—a very difficult task at the intensities usually discussed. Creating even a small chip in the mirror would cause the laser to destroy itself in a short time, since it would absorb its own energy. Thus, it would probably not be possible to defend against such anti-laser weapons except by denying entry into space to all suspicious satellites.

Because a laser defense would be a system, rather than a collection of independent parts, one means of attack would be to interfere with the links among the components. In any laser system, there would probably have to

Lasers, it is claimed, would put an end to the nuclear arms race and enable the United States to live in peace under a shield of light.

be a command communication link between Earth and the laser satellites. This link might be disrupted by many things, among them the electromagnetic pulse produced by nuclear explosions in the atmosphere. And even if the connection between ground and satellite were secure, it would still be possible to diminish the system's effectiveness by disrupting the coordination between laser satellites, since each laser would have to know what targets other lasers were shooting at, so as not to waste its own fire or let missiles through.

To aim at a target, a laser weapon would need detectors with their own large optics. Because the detectors would have to be highly sensitive in order to pick up the feeble signs of an ICBM in flight hundreds of kilometers away, they would be easy to interfere with. This could be done by blinding the detectors with a ground-based laser, by lighting flares to confuse the detectors, or by launching decoys. Since it is practically impossible to distinguish decoys from warhead-carrying missiles, lasers would have to spend valuable time shooting at decoys. Decoys might also induce aiming or tracking errors. Another possibility might be to build "stealth" missiles (just as Stealth bombers are being considered), or to hide the missile itself behind a screen, so that although it would be detectable it would not be targetable.[2]

As already mentioned, missiles can be hardened against laser light. Current Soviet liquid-fueled missiles might be vulnerable to as little as 300 joules per square centimeter of laser energy incident upon their surface, because the stress produced by the laser would combine with the stresses produced in the missile during launch. However, present-day re-entry vehicles (that is, the warheads themselves) are hardened to about 7,000 joules per square centimeter. This is a by-product of their being made to withstand both re-entry into the atmosphere and X-rays produced by nuclear explosions. One estimate is that the limit of ablative coatings – in which the protective shield flakes off as it heats up – is as much as 20,000 joules per square centimeter.[3] And there is no predicting what the limits of other missile hardening technologies may be. By rotating the missile in flight, the laser's energy could be more widely distributed over the missile surface, effectively increasing its hardness more than three times. Because techniques of missile hardening can be developed relatively quickly a laser defense would be subject to sudden obsolescence.

Excerpted from President Reagan's March 23 speech:

I am directing a comprehensive and intensive effort to define a long-term research and development program to begin to achieve our ultimate goal of eliminating the threat posed by strategic nuclear missiles. This could pave the way for arms control measures to eliminate the weapons themselves.

Whatever countermeasures have already been discovered, it is likely that efforts to find still better ones will be spurred on by continuing development of laser weapons. And the potential for development of countermeasures forces the designer of a laser system to find a way to obviate them, or to build another weapon which will fill in the gaps left by the laser.

Advocates of space lasers see them as essentially defensive, and claim that it is unlikely that deploying such a system would adversely affect the arms race or America's relation in general with the Soviet Union. But considering the structure of the nuclear balance, in which offensive weapons are designated as a deterrent to attack, the classification of a weapon as defensive is practically meaningless. The Soviets would probably view a U.S. laser system as offensive, in much the same way that Soviet civil defense plans are interpreted in the United States as a sign of Soviet aggressiveness.

For Moscow to look upon U.S. deployment of even a small system of lasers as a preparation for attack on the Soviet Union is not unreasonable. One mission well suited to a system of only a few laser weapons would be to cover a counterforce first strike – against strategic military forces, not civilian targets. The position of the military today is that the danger of a counterforce surprise attack can be greatly reduced by planning to launch the targeted missiles before the incoming missiles arrive: the tactic of "launch on warning." However, if four or five lasers were orbited – not nearly enough to *defend* against a surprise missile attack – their orbits could be coordinated so that they could cover all necessary targets within a certain time window.

These few lasers could be used to prevent missiles from being launched on warning during the half-hour interval of a counterforce attack; or, at least, so some military planners claim. And because of this capability to back up a counterforce strike, even a few lasers put into orbit could stimulate the arms race, just as the claimed development of accurate "silo-killing" missiles has done.

Another problem with space laser weapons is that they would have to be on hair triggers. To be effective, a laser would have to fire at a missile during the missile's boost phase. In a mass attack, the very size of the missile launch would be a clear indication of hostile intent. But if just one or two

Despite speculation that lasers could shift the emphasis of nuclear strategy from deterrence to defense, it is unlikely that a laser ABM could do more than supplement a deterrent force.

launches were seen, there would be a serious question as to whether they were for aggressive purposes or not. Because of the short time available to make a decision, unless there were a policy against using lasers except during mass launches, a peaceful satellite might be shot down by mistake.

This problem is deepened by the likelihood that space lasers would be mined. In order to counteract a U.S. laser, for instance, the Soviets might orbit an explosive device nearby, designed to destroy the laser when commanded to do so. Equally, the mines might be countermined. In any crisis, there would be a temptation to use one's mines before the other side did. The existence of space lasers might tend to escalate a crisis.

The most likely Soviet response to a U.S. laser system would be an increase in Soviet spending on cruise missiles and low-altitude bombers, weapons which are virtually immune to space lasers. But even though lasers are meant specifically to shoot down ballistic missiles, it may be that the most effective response to the deployment of a laser system would be to increase the numbers of ballistic missiles, or to take even drastic measures to harden missiles. For any of the laser systems considered above to compensate for an increase of, say, 25 percent in the size of the Soviet missile force, the number of lasers in orbit would have to be raised by 25 percent.[4] Similarly, doubling the hardness of missiles would require doubling the number of lasers.

It is a mistake to consider the cost of a laser system as a one-time expense which can be borne without regard to the economies involved. If it costs more to shoot down a missile than to add one to the missile force, then the United States would probably lose a laser *versus* missile race. Of course, the Soviets might find it less expensive to harden old missiles, or to build cruise missiles or bombers, than to add new ballistic missiles.

Supporters of space lasers tend to view them as a kind of ultimate weapon. They feel that whichever nation first deploys them will not only be able to protect itself against nuclear attack, but control space as well. Senator Malcolm Wallop of Wyoming, a prime supporter of laser weapons, expresses the fear that "as the Soviet Union perfects the kind of space-based laser system that can deny one or two missiles entry into space, we will have to tell them in detail the payload of everything we send up from there on, or they will shoot it down, treaty or no treaty, and we may never get to deploy [our own lasers]."[5] Wallop urges the military to increase its research efforts so that a laser system can be deployed in five or 10 years. This, he says, would enable the United States to prevent the Soviet Union from orbiting its own lasers. Wallop succeeded in getting a bill passed which adds $50 million to the 1982 budget for space laser research, and this was a compromise. His original intention was to add $250 million to the research budget and stipulate that a prototype weapon be built by 1985. Yet most experts think that it will be at least 20 years before working space laser weapons can be built, and some believe it simply cannot be done.

Official Pentagon policy is to proceed with the development of lasers, large-scale optics and other equipment associated with a space-based laser weapon, but not to direct effort toward construction of prototype weapons. This policy allows the United States to maintain its position technologically with respect to the Soviets, helps determine what sorts of laser missions are and are not practicable, provides a basis for assessing Soviet technology, and gives the potential for warning of a Soviet breakthrough in laser technology. The budgets for laser research in the Air Force and the Defense Advanced Research Projects Agency have increased steadily to a total in 1983 of about $470 million, and they are expected to increase more rapidly in the future. Contracts have already been let to assess the vulnerability of missiles to laser light, to design pointing and tracking devices for lasers, and to develop large-scale optics.

While the Pentagon has given no indication of intending to build a prototype weapon, defense contractors are more ambitious. Lockheed Missiles has already unveiled a model of a space-based laser weapon, though it seems to have more publicity than technical value.

In the past, military projects have often proceeded despite a lack of strategic or technological justification. Sometimes, as with the nuclear-powered airplane, the only result was wasted money. Other times the price has not been so cheap: The ABM missile project has come and gone but MIRV—which was justified as a means of countering ABM—is a permanent legacy of escalation. Space lasers also have the potential to escalate the arms race and expand it into space. This potential completely dwarfs the benefits lasers might bring as a defense against missiles. □

1. These figures were arrived at through a calculation involving the power of the laser, its distance from the target missile, the hardness of the target, and the need, in theory, to be able to destroy 2,000 missiles that might be launched in an all-out enemy attack. The optimal altitude for a 10-megawatt, 10-meter diameter laser turns out to be 150 kilometers; however, this altitude leads to an unstable orbit. The given figures are based on an altitude of no less than 250 miles. For details on how the calculation was done, please contact the author.

2. See, for example, Richard Garwin, "Are We on the Verge of an Arms Race in Space?," *Bulletin* (May 1981), pp. 48-53.

3. *Aviation Week and Space Technology* (Feb. 16, 1981), p. 17.

4. This is because lasers, in most cases, could not be stationed at their theoretically optimal altitudes. See note 1.

Space Weapons

History and current debate

Richard Garwin and John Pike

Effect on strategic stability

Yevgeny P. Velikov

*President Reagan's proposal to create a comprehensive space-based anti-missile defense system has been vigorously challenged by scientists on technical as well as strategic, political and even moral grounds. Richard L. Garwin has been prominent among the challengers. In February 1983 he and Carl Sagan authored a petition urging the United States, the Soviet Union and "other space-faring nations" to agree to ban weapons of any kind from space and in particular "to prohibit damage to or destruction of satellites of any nation"—a petition signed by dozens of other leading U.S. scientists (*Bulletin, *November 1983).*

In the following article Garwin and John Pike provide a comprehensive argument against the Reagan proposal, concluding with an urgent call for negotiations. Their article is followed by one from Academician Yevgeny P. Velikhov of the Soviet Union. While agreeing in essence with the Garwin-Pike analysis, Velikhov also calls for a diversion of funds from weapons research into such joint U.S.-Soviet projects as space exploration.

Several prominent scientific organizations share the Bulletin's *concern with the militarization of space and either have published or are preparing studies of the military uses of space. A joint project of the Brookings Institution and the Massachusetts Institute of Technology has recently resulted in a book,* Ballistic Missile Defense. *In late March the Union of Concerned Scientists released the 106-page report of a study panel,* Space-Based Missile Defense. *The Federation of American Scientists has now made available a book-length study,* Anti-Satellite Weapons: Prospects and Implications. *The American Physical Society has established a task force to study and evaluate directed energy weapons. And finally, the American Academy of Arts and Sciences has begun a study of weapons in space, which is to be ready for publication by the end of this year. The* Bulletin *will continue to report on problems and developments in this area.*

History and current debate

by Richard L. Garwin and John Pike

THE QUESTION of space weaponry has become more urgent and much more widely discussed since one of the authors last wrote about the subject in these pages.[1] Two types of concerns are evident—those connected with anti-satellite capabilities and activities (ASAT) and those connected with global defense against ballistic missiles. This article will survey these two topics and their important, but limited interaction. Our conclusion, based upon many years of involvement with strategic offensive weapons, strategic defenses and military space systems, is that an effective ban on anti-satellite activities and capabilities and on weapons in space would best serve the national security interests of the United States. Furthermore, an effective ban is feasible and can be negotiated quickly.

Overview: history and present status

For the past 25 years, space weapons have remained largely in the realm of speculation. With President Reagan's Star Wars speech of March 23, 1983, their discussion assumed a certain immediacy, but underlying developments are equally to blame. Space weapons include systems that either are based in space or are intended for use against targets in space, such as satellites. In the past, the poor performance of such systems made it rather difficult to identify useful military missions for them. Now present and prospective improvements in sensor and computer technology, as well as in kill-mechanisms such as directed energy systems, have encouraged a reexamination of the case for space weapons.

Richard L. Garwin is adjunct professor of physics, Columbia University and a fellow at the IBM Thomas J. Watson Research Center, Yorktown Heights, New York (10598). He has been working on defense issues and military technology for over 30 years.

The technology of space weapons might have changed, but the strategic and political questions concerning them have not. It is important to ask whether any missions for space weapons would result in a net improvement in U.S. national security or in the prospects for peace.

During the 1960s both the United States and the Soviet Union developed anti-satellite systems with marginal capabilities. Because of their limitations, and because of the newfound value of satellites themselves, these systems generally did not attract much interest.

The two early U.S. ASAT systems suffered from several common defects. Deployed in very small numbers, they were capable of rather modest rates of fire, and their limited range meant that they had to wait for an intended target to pass within a few hundred miles of their base before an interception could be attempted. The use of high-yield nuclear warheads furthermore posed the risk of considerable collateral damage to friendly satellites. Neither of their potential missions—defense against Soviet orbital nuclear weapons and deterrence or defeat of Soviet attacks on U.S. reconnaissance satellites—seemed particularly compelling by the early 1970s.

Although the early history of Soviet ASAT efforts remains clouded by official secrecy, their capabilities seem no more than slightly behind those of the United States. A clear indication of Soviet work in this area came in 1968, with the initial test of an orbital ASAT, colloquially known as a "killer satellite," reminiscent of the abandoned U.S. SAINT

(Satellite Inspection Technique) program. The Soviet ASAT is launched by a modified version of the SS-9 ICBM. The intercept vehicle itself has a mass of 2,300–3,300 kilograms, and 1,000 kilograms of maneuvering fuel would give it a maneuvering velocity change of as much as one kilometer per second. The system has been tested 20 times, using a variety of trajectories that take from 45 minutes to several hours from launch to intercept, reported at a maximum altitude of 2,300 kilometers. Initial tracking of the target is reported to use ground-based radars. An on-board active radar guidance system achieved 10 successes in 14 attempts. Beginning in 1976, a more sophisticated passive system, perhaps using an optical sensor, has been tested six times with no more than one success. Several types of payloads might have been carried on the interceptor.

In 1979, Air Force Chief of Staff Lew Allen characterized the Soviet ASAT as "having a very questionable operational capability." The variety of anti-satellite components and techniques, as well as the fitful and irregular pace of the tests, suggest that the program is as much an effort to develop a generic military technology as it is to deploy a weapon to counter a specific set of targets. The limited maneuvering capabilities require that it be placed into an orbit that is generally similar in inclination to that of its intended target. Thus the interceptor cannot be launched until the orbital ground track of its target passes to within a few hundred kilometers of the launch facility. This requirement may not be satisfied for several hours, even as long as a day, after a decision has been made to conduct an intercept. The small number of launch pads available for ASAT launches imposes a further operational limitation.

The present Soviet ASAT potentially threatens low-flying U.S. space assets, including photographic reconnaissance satellites and the Transit navigation satellites. However, most important U.S. satellites, such as those used for early warning and communications, are in geosynchronous orbit (GEO) at 36,000 kilometers above the Earth—far beyond the demonstrated range of the Soviet ASAT. The threat to satellites in lower orbits will decline in coming years, as various survivability programs for them are implemented, such as the transfer of the navigation support mission to the Navstar satellites, which orbit at an altitude of 20,000 kilometers.

DURING the 1970s both countries greatly increased their reliance on space to support conventional and strategic forces on Earth. In the absence of restraint these numerous military support satellites could be an incentive to develop new and more capable ASATs in order to reduce enemy military effectiveness, with serious negative implications for both crisis and arms-race stability.

The Soviet resumption of ASAT testing in February 1976, after a pause of over five years, was the proximate impetus for the development of the new U.S. ASAT, initiated in the closing days of the Ford Administration. Major ASAT funding increases had been proposed prior to the resumption of Soviet testing, and the Carter Administration subsequently concurred in this decision as part of a multi-pronged effort that included programs to enhance the survivability of military satellites and negotiations with the Soviet Union to limit ASATs.

The ASAT configuration chosen for development is the Air-launched Miniature Homing Vehicle (ALMV), delivered by a small two-stage rocket to be carried on an F-15 fighter aircraft. The SRAM (Short-Range Attack Missile) first stage and the ALTAIR-III second stage would be launched from the F-15 guided by a programmed-inertial guidance system, to intercept a satellite whose orbital parameters had been determined by ground-based sensors. Weighing about 1,200 kilograms, the F-15 launched rocket would boost a Miniature Homing Vehicle (MHV) which would maneuver to intersect the target satellite's orbit, destroying the target on impact.

The maximum altitude at which the ALMV can attack satellites may be in the range of 2,000 kilometers. Whatever the "reach," or cross-range capability, of the ASAT, the F-15 can carry it to launch points several thousand kilometers from the home air base. With the use of mid-air refueling and basing at forward facilities such as Diego Garcia or Ascension Island, the ALMV could be used to attack low-altitude satellites at almost any point in their orbit. This system will be capable of attacking a wide range of Soviet military satellites, including all their photographic and electronic intelligence satellites, the Radar Ocean Reconnaissance Satellites (RORSATs), and the *Salyut* space station. Communication and early warning satellites in highly elliptical 12-hour *Molniya* (lightning) orbits can be attacked at the low points in their orbits, which are over the Antarctic Ocean. This would require forward basing of the F-15 at Diego Garcia, Ascension Island or North West Cape, Australia, as well as aerial refueling.

The first flight test of the ALMV booster was on January 21, 1984. The first test of the system against a target in space will come at the end of 1984, and at least ten additional such tests are planned before the system becomes operational in 1987. Over 100 interceptor rockets are scheduled for procurement at a total cost of $3.6 billion, although this cost is expected to increase. About 50 F-15s will be modified to carry the ASAT, permitting the entire arsenal of interceptors to be fired within a few hours.

To the extent that the United States or the Soviet Union depends or is believed to depend on satellites for strategic deterrent capability, acquisition by either country of an ability to destroy the opponent's early-warning, communication and navigation satellites could provide an incentive to initiate an anti-satellite campaign that would greatly degrade the capabilities of the opponent's military forces. Should *both* countries achieve such a capability, each would have considerable incentive to initiate preemptively such a

An F-15 plane equipped with anti-satellite weapons (ASAT), currently being tested by the U.S. military.

campaign during a time of acute crisis. Both instances would decrease crisis stability and increase the threat of war. If a strategic defense, especially a perfect or disarming one, depends on satellites, those satellites are at particular risk. The possibility that accidental malfunctions of vulnerable satellites could exacerbate an on-going crisis also cannot be ignored.

Today we are confronted by the third generation of anti-satellite weapons. The early U.S. ASATs, flying short ballistic trajectories to deliver nuclear warheads, were soon followed by the more advanced Soviet ASAT, which orbits a conventional explosive charge that maneuvers to within range of its target. Now the United States has begun testing an even more advanced air-launched system. In the absence of mutual restraint, it can only be a matter of time before both countries field even more capable systems, thus placing arms race stability at risk.

More advanced ASATs may pose increasingly serious challenges to the 1972 ABM Treaty. U.S. (and presumably Soviet) ASATs have incorporated technologies derived from ballistic missile defense systems. In the future, systems that were nominally for anti-satellite purposes could be used to approach ballistic missile defense capabilities that are otherwise prohibited by the ABM Treaty. The more capable ASATs of one side might create such suspicions on the other, raising the specter of a gradual erosion of the Treaty regime under the guise of an ASAT competition.

President Reagan's Star Wars speech, however, has posed a more immediate challenge to the ABM Treaty. Although the Administration has proposed no immediate abandonment of the Treaty, a number of likely development and test programs may raise questions of compliance with the letter of the Treaty. More important, if the doctrinal implications of the President's initiative gain general acceptance in the United States, the demise of the Treaty will soon follow. Under these circumstances, the Soviet Union can hardly be expected to sit back and wait for the United States to choose a convenient time to announce its renunciation.

The strategic and political rationale of the ABM Treaty was developed in an era of technology that both superpowers have now surpassed. But technological innovation does not invalidate that rationale, nor lessen the Treaty's importance. No ABM system in prospect could provide a perfect defense against attack. Such systems are subject to passive and active countermeasures, including direct attack on the defensive system itself, and a ballistic missile defense system which seems promising against the existing strategic offensive force may be defeated at little cost. A ballistic missile defense system would be much more effective in defending against a small and disorganized retaliation than it would in defeating a massive and well-organized first strike. This disparity would provide incentive for preemption (by either side) that would undermine crisis stability.

Arms-race stability would also suffer, as the most straightforward countermeasures would be a simple proliferation of offensive arms. Since each country would tend to overestimate the effectiveness of the opponent's defensive system, while underestimating the effectiveness of its own defenses, conservative planning would generate ever higher requirements for offensive forces. There is no rational upper limit to this competition, save perhaps the carrying capacity of the country's economy.

These systems would require funding on an unprecedented scale. Various estimates place the cost of two layers of ground-based ABM systems at $200 billion, and the cost of the space-based component at perhaps $500 billion. To these costs should be added those of continental air defense and civil defense, which would push the cost of the total strategic defense package to over $1 trillion.

These estimates, however, do not fully capture the magnitude of the problem, since such defensive systems will have to be maintained, modified and upgraded in response to the changing and inexorably expanding offensive threat. What is really under discussion is the addition of perhaps $100 billion annually to the defense budget, perhaps as soon as the mid-1990s. Given the negative impact on crisis and arms-race stability of strategic defensive systems, it is difficult to see the justification for expenditures of this magnitude.

Prospects

In most important respects the new U.S. ASAT constitutes an order of magnitude improvement over the existing Soviet ASAT. The flight time from launch to intercept is one-tenth as long. The total number of interceptors will be ten times greater. The Soviet ASAT booster is ten times the size, and 100 times the mass of the U.S. ASAT booster, and the disparity between the sizes of the actual intercept vehicles is even greater.

It is clear, however, that the new U.S. ASAT is not the last word in weapons of this sort. In the absence of negotiated restraint, both the United States and the Soviet Union are likely to develop even more capable anti-satellite weapons, which will share two disturbing characteristics: the ability to attack satellites in high orbits and an increasing resemblance to anti-ballistic missile systems. Both are good reasons for precluding the development of such weapons.

The United States has already studied several advanced ASATs that would use the Miniature Homing Vehicle and more capable boosters. A larger air-launched booster rocket could extend the range of the F-15 system so that it could attack satellites at an altitude of several thousand kilometers. Above this range, the advantage of using air-launching to match the orbital ground track of the target diminishes. Satellites at higher altitudes could be attacked by launching the MHV atop a larger rocket, such as the Minuteman

or the Trident. These systems could be developed in a few years time, at a cost of several billion dollars.

A transfer from low Earth orbit (LEO) to inject into GEO with minimum additional energy requires a velocity increase of 3.6 kilometers per second -- about a factor three increase in launch weight (or a factor three reduction in available payload). This does not include the plane change required if one insists on *co-orbital* trajectory; that amounts to almost another factor two if one starts with an orbital inclination of 60 degrees corresponding to Soviet launch latitudes. The flight time from launch to interception of satellites at semi-synchronous or geosynchronous orbits would be several hours, permitting evasive maneuvering by the target. Such long flight times would also result in loss of surprise, which is important for attacks on targets such as early-warning satellites.

Thus the use of directed energy weapons has attracted some attention. These weapons could be either ground-based or space-based. Published reports suggest that the United States could test a ground-based laser against targets in geosynchronous orbit by the end of this decade. Tests of a space-based laser of somewhat lesser range could begin by 1992. However, this space laser would pose serious questions concerning compliance with the 1972 ABM Treaty, and thus no decision has been made to conduct such a test.

The Soviet Union could also introduce a variety of improved ASATs. With continued testing, they will eventually perfect the thus far unsuccessful passive optical guidance for their present ASAT. Because the general trend in the Soviet ASAT program has been toward reducing the flight time from launch to interception, we might expect to see the introduction of a non-orbital "pop-up" ASAT, which would intercept its target within a few minutes after launch. The present Soviet system could be used in this mode if it were provided with a guidance system capable not only of bringing it to a specified point in space, but also at a specified time. Large ground-based radar could be used to overcome target countermeasures such as maneuvering, jamming or decoys. These radars could also be used in support of an air-launched system similar to the new U.S. ASAT, which could use planes such as the Foxbat fighter or the Blackjack bomber as launch platforms. Such systems would pose serious problems for verification of a treaty that included a ban on deployment.

For several years Defense Department officials have reported that the Soviet Union might soon launch a large laser into orbit. Given the pace and schedule of the U.S. space laser program, the state of Soviet work in this field and the Soviet tendency to move to field testing of prototypes at an earlier stage than is the case in U.S. programs, this prediction is not unreasonable. It tends to create the impression that a Soviet space laser would convey a military benefit, which is not the case. Nevertheless, testing of a space-based weapon would be regarded as development of a space-based ABM system, specifically banned by the ABM Treaty.

IN HIS MARCH 23, 1983 speech, President Reagan asked "the scientific community in our country . . . to turn their great talents now to the cause of mankind and world peace: to give us the means of rendering these nuclear weapons impotent and obsolete. . . . I am directing a comprehensive and intensive effort to define a long-term research and development program to begin to achieve our ultimate goal of eliminating the threat posed by strategic nuclear missiles." And on March 27, 1983, Secretary of Defense Caspar Weinberger said on the "Meet the Press" television program, "The defensive systems the President is talking about are not designed to be partial. What we want to try to get is a system which will develop a defense that is thoroughly reliable and total, yes. And I don't see any reason why that can't be done."

The President and the secretary are clearly talking about "assured survival," as an alternative to deterrence of nuclear war by threat of retaliation. But to eliminate the fear of nuclear weapons, even of delivery of nuclear weapons by ICBMs, in the presence of the almost 10,000 strategic reentry vehicles on either side, is more than we believe the United States or the Soviet Union can accomplish. ICBMs take about 30 minutes to fall to their targets, as do submarine-launched ballistic missiles (SLBMs) of intercontinental range. Shorter-range SLBMs and the notorious intermediate-range nuclear forces (INF) may take ten minutes. Thus to be useful against ballistic missiles a system must do its job within 30 minutes or not at all. A space-based defense which would prevent 50 percent of the reentry vehicles from landing would be doing a pretty good job; one which prevented 90 percent would be an active defense beyond experience. Yet achieving even such defenses would simply result in the elimination of some of the marginally useful targets for nuclear weapons and would focus the remainder (for

Figure 1. Destructive mechanisms

Mechanism	*Device*	*Operation*
Pulsed laser	X-ray laser Excimer laser	Deliver a high impulse or shock to a missile to break or blow a hole in it and cause structural collapse of the booster
Continuous wave laser	Free electron laser Excimer laser Hydrogen fluoride/ deuterium fluoride laser	Stay on target until a hole is burned through it, then switch to another target
Continuous particle beam	Neutral particle beam	Destroy internal weapon components
Mass accelerator	Kinetic energy rail gun	Accelerate small homing hit-to-kill vehicles (non-nuclear kill)
Self-propelled missile	Miniature homing vehicle	Infrared sensor senses spot of radiation from incoming re-entry vehicle. Homes in and destroys with hit-to-kill vehicle

deterrence or for "compellence") on the society's centers of value—industry and population.

Recognizing the difficulty or impossibility of having any system which will provide 99.99 percent protection (to reduce the expected number of warheads striking their targets to less than one), advocates of such programs rely on arithmetic, asserting that a defense of four totally independent layers, each of which allows only 10 percent of the incoming weapons to leak through, will allow an average of only one in 10,000 weapons through all four layers. This assumes that there are no common-mode failures (that is, if a reentry vehicle leaks through one layer, it will automatically leak through another) in which case the number leaking through increases by a factor 10, 100 or 1,000. Furthermore, the *assumption* of four layers, each with 10 percent leakage, does not guarantee the existence of even *one* such layer. Finally, if four independent defenses can be found which are compatible with layering, all four must be paid for, maintained, and not allowed to interfere with one another.

For 20 years the fact that one can "hit a bullet with a bullet" has not solved the ballistic missile defense problem. That solution requires not only the application of science and technology but also the assurance that the scientists, technologists and investors of the other side will not be able to *counter* the defenses. The fact that one nuclear warhead can kill a million people and do at least $100 billion worth of property damage makes it very important to prevent access by even one reentry vehicle. Obviously it is essential to know whether such a perfect defense is possible. A nation possessing such a defense need not be deterred from destroying its adversary, since it could protect totally against retaliation in case it launched a nuclear attack. Of course, not only the feasibility but also the *counterability* of such a defense is important, and neither side need promise to lie down and play dead if the other side develops and deploys a defense which promises to be effective against the "unadapted" force.

We went through this in the 1960s, when U.S. perceptions of the emergence of a ballistic missile defense by the Soviet Union led Secretary of Defense Robert McNamara to authorize the development of MIRVed Minuteman missiles, thereby countering the nascent Soviet ballistic missile defense and increasing greatly the flexibility of the U.S. strategic offensive force and the threat to the Soviet Union.

What is new? Not the desire to feel free from the threat of destruction! That is as old as human beings, and many have availed themselves of that desire by retreating to a world of unreality. New are the existence of high-speed flexible computation in small packages; optical lasers for viewing and for concentrating potentially damaging radiation at a distance; complex focal-plane arrays for viewing large areas with reasonable resolution; and the prospect of the soft X-ray laser pumped by a nuclear explosion which can hope to focus one one-thousandth or one ten-thousandth of the energy of a nuclear weapon into one-millionth or one-billionth of the sphere, corresponding to an increase of X-ray intensity over that provided by the same nuclear explosion by a factor 100 or 1,000 (or 100,000 or one million).

Furthermore, a ten-fold larger nuclear weapon exploded at 1 percent of the distance would correspond to a 100,000-fold increase in intensity over the reference weapon, so that there is a tradeoff (assuming operationally and technically feasible X-ray lasers) between their use and the pre-deployment of X-ray defenses. In fact, the X rays from a nuclear explosion may be much more effective than those from an X-ray laser, for the same energy delivered to the target.

ANY SUCCESSFUL manager or leader strives to eliminate potentially unsuccessful candidates as quickly as possible, and if defensive systems can be shown to be vulnerable, that is as good a way to eliminate them as showing them to be technically infeasible. Because defensive systems are far more complicated than offensive systems, the offense has time to adapt to a defense of potentially great effectiveness.

Thus the United States has long done major research and field testing on penetration aids against terminal and midcourse ballistic missile defense. It may not carry those "penaids" on its ICBMs and SLBMs since it is confident that no such defenses exist. Nevertheless, if the Soviet Union initiated a multi-year deployment of ballistic missile defenses the United States certainly would have pen-aids ready in time. At the cost of a small fraction of the warheads now carried on the strategic offensive force, the remaining warheads would have a high probability of penetration to their targets. An estimate of the penetration probability of the *unadapted* force might yield a totally different result, but it would not be relevant.[2]

Midcourse intercept of reentry vehicles continues to be frustrated by the feasibility of balloon decoys to fool radar and infrared and optical sensors.

The boost phase of an adapted offensive force lasts a short time (40–100 seconds), and defensive systems stationary with respect to the likely launch areas are either based on the Earth, in its atmosphere or in GEO (in any case 10,000 or 40,000 kilometers from the launch). It is thus not possible to attack with rocket-propelled defenses, unless the rockets can be fired *before* ICBM or SLBM launch, in confidence that the offensive weapons will be launched only to be destroyed! Considering systems based in orbit, cross-track capability out to 250 kilometers could be obtained from vast numbers of small interceptors which burn 90 percent of their initial mass as rocket fuel, but some 3,000 would be required in orbit to have one close enough to destroy a single ICBM. If no more than 100 silos are located within a circle 500 kilometers in diameter, 300,000 of these orbital rockets would be required even if they were 100 percent effective and reliable. (Of course, a mere 3,000 "space trucks" each carrying 100 interceptors could do the job, but they would be vulnerable to space mines.)

As for beam weapons, a simple calculation shows that a fluence (energy per unit area) exceeding ten kilojoules per square centimeter is required to damage a rocket booster which has been modified to survive against optical or X-ray lasers. For optical lasers, we have the usual tension bet-

ween basing in synchronous orbit (at some 40,000 kilometers from their targets and viewing the ICBM or SLBM launch sites all the time), and basing them in LEO, where they could use effective ranges as short as 1,000 kilometers. But in LEO they would have to reckon with the facts that the Earth's surface area is 500 million square kilometers and that the area coverable by a weapon at 1,000 kilometers is only 3 million square kilometers. If the effective range of a laser were to be taken as 1,000 kilometers instead of 40,000 kilometers, its power need be only one sixteen-hundredth as great (or its mirror diameter one-fortieth as large), but it would have to slew over a much wider angle to catch all the boosters within its purview, and 170 lasers in LEO would put only one within range of a particular launch. Furthermore, any laser would have to be able to destroy as many as several hundred boosters during the couple of minutes of boost phase.

Assuming the existence of one-megawatt lasers in the midwavelength range (perhaps three microns) and a boost phase for an adapted strategic offensive missile of 120 seconds, a laser could destroy *one* ICBM if it illuminated it for 100 seconds at a power of 100 watts per square centimeter to meet the assumed kill criterion of 10 kilojoules per square centimeter. At this wavelength, however, a mirror three meters in diameter would provide a spot 100 meters in diameter and the intensity from a 100-megawatt laser would be only *one* watt per square centimeter instead of the required 100. Therefore to destroy even a single ICBM in boost phase from GEO would require an optically perfect mirror 30 meters in diameter and a laser of 100 megawatts. One can *assume* that the problem of mirror accuracy can be solved by segmenting the mirror and controlling it adaptively, and that the problem of increasing laser power will yield to development. Nevertheless, these are only assumptions, and the problems of transporting the laser and its fuel to GEO and paying for it will remain. At a laser yield of about 500 joules per gram of fuel, the fuel for a single such intercept (using 100 megawatts of light for 100 seconds) weighs 20 tons and would take some 3 shuttle launches at $90 million each, to place the fuel for a single intercept into GEO ($300 million).

If one could have a laser of 0.3 micron wavelength (ultraviolet) instead of 3 micron and a mirror 30 meters in diameter with adequate reflectivity at this wavelength, and with the required ten times better perfection of its figure, the fuel requirement would fall by a factor 100. Nevertheless, such vastly expensive systems on satellites are easily countered by space mines or other ASAT means. No less a defense proponent than Edward Teller has testified and indicated in many interviews that no defensive system can depend upon satellites because they are "costly to put up and cheap to shoot down."

Furthermore, the vulnerability of the booster itself can be greatly reduced by various means: by rotating it, thereby spreading the heat over a larger region; by concealing it in smoke; by interposing reflecting foils so as to hide the booster itself; by deceiving the laser as to its position; and even by launching dummy boosters without warheads or silos, to provoke the defense to attack substantially more "ICBMs" than really exist, thus driving up the cost of defense. The ultimate problem for satellite-based lasers, or any orbital defensive system, is vulnerability to space mines —small satellites based in orbit in peacetime, remaining always in lethal range of their quarry satellites and ready to explode on command.

Some (notably George Keyworth, Jr., the President's science advisor) have advocated reducing the cost of such a system by placing the lasers and their fuel supply on the ground, directing the beam upward through the atmosphere by adaptive optics to compensate not only for imperfections of the mirror but also for the turbulent optical properties of the atmosphere. Such a ground-based laser would illuminate a relay mirror in orbit, which would then send the beam to other "fighting mirrors" which would direct the beam first at one booster and then at another. These mirrors also would be of very substantial size and cost and also vulnerable to space mines. As an additional element of vulnerability, the ground-based lasers could be put out of action by cloud, dust or sabotage.

"The President's defensive technologies initiative is a spectacularly ambitious one. Quite simply, it will require a scientific, technical, military, and organizational undertaking that will dwarf anything ever before mounted by the human race. . . .

I believe that mutual assured destruction is a morally bankrupt philosophy that places Government in the untenable position of refusing to defend its citizenry. What the President has proposed is no less than a moral recovery in American strategic policy which would take us from the horror of MAD to the promise of mutual assured protection. It is a goal which deserves the fervent support of all who yearn for a world safe from nuclear weapons. Unless we are willing to accept the prospect of a nuclear Pearl Harbor from space, we must now join the President in a new national commitment to mutual assured protection."

—*Ken Kramer (R-Colorado)*

Statement before the Subcommittee on Research and Development, House Armed Services Committee, Nov. 10, 1983, advocating the People's Protection Act. The Act was co-sponsored by Representatives Montgomery (D-Mississippi), Whitehurst (R-Virginia), Badham (R-California), Skelton (D-Missouri), Corcoran (R-Illinois), Davis (R-Michigan), Daniel Crane (R-Illinois), Hunter (R-California), Dyson (D-Missouri), Hartnett (R-South Carolina) and Skeen (R-New Mexico).

The other type of damaging energy that can be projected at nearly the speed of light consists of particles given their energy by particle accelerators in space. Although charged particles can be accelerated with efficiencies above 50 percent, they are bent by the Earth's magnetic field. Conversion of the charged particles to neutral particles can also be done with reasonable efficiency, but the quality of the

beam is spoiled, and the angular spread introduced dilutes the fluence at the target. The negative hydrogen atom, however, is unique among charged particles and would present a considerably smaller angular spread. The problems of developing and deploying a particle-beam defense even against a non-reactive adversary are enormous, but the system is ultimately vulnerable to space mines or to other ASAT weapons.

NEW SINCE Garwin's article in the May 1981 *Bulletin* is the X-ray laser driven by a nuclear explosive.[3] This "recombination-pumped" laser produces a low-density plasma by absorbing the energy from a nuclear explosion in space, at some 100 centimeters from a set of metal wires pointing at a distant target. Almost all the energy from the fission or fusion process in a space explosion resides initially in the thermal energy of the bomb materials or in the radiation energy of its volume; this energy can be radiated as thermal X rays before the materials of the weapon can expand far enough to acquire a substantial fraction of the bomb energy as kinetic energy. The relatively "hard" X-ray photons from the bomb are to be absorbed in copper or zinc, expanding the wires which continue to absorb photons and lose electrons, which then recombine selectively to populate the upper levels of the ions. Since no mirrors are available at these X-ray wavelengths and fluences, the angular aperture of the X-ray beam is at least as big as the angular aperture of one of the lasing rods—roughly the ratio of width to length—which in the example is about 1,000 microradians.

There are many problems in making a laser and many further problems in making an effective weapon from that laser. One might hope to achieve a transformation of 0.1 percent of the bomb energy into directed X rays, and if one uses the one milliradian angular aperture, this corresponds to a fluence from GEO of 0.1 percent of the bomb energy (which might be 20 kilotons) over a diameter on the order of 40 kilometers, or 0.01 joules per square centimeter which would not damage missiles or even satellites. The mechanism of damage by a short pulse of soft X rays consists of the blowoff of the thin surface layer absorbing the X rays, creating a shockwave going through the skin of the missile and an impulse communicated to the skin.[4] Because the laser X rays in the example are so soft, they are absorbed in a very thin layer of the order of 0.1 milligram per square centimeter and the resulting impulse is substantially less than that communicated by a similar fluence of hard X rays.

The particle beams and soft X-ray lasers can be negated by the same hardened, fast-burn boosters which cause so much trouble for a chemical laser system. Burning out below 80 kilometers, the booster is shielded by sufficient air to absorb the X-ray laser beam kilometers from the booster and to strip any hydrogen atom beam, allowing the resulting protons to be swept off target by the Earth's magnetic field.

Options

The preceding technical sketch suggests the vast range of choices available for attack on fragile satellites and the much greater difficulty associated with a defense which would "render nuclear weapons impotent." But as ASAT weapons, lasers and particle beams seem to offer only increased delay and higher cost, in comparison with space mines for which present technology would suffice.

The 1972 ABM Treaty already bans the development or testing (and even more the deployment) of ABM systems that are mobile, space-based or air-based, and President Reagan has stated that the United States would explore defensive possibilities within the constraints of that Treaty. Furthermore, many of the capabilities conferred by the adversary's satellites can be negated by means other than ASAT weapons—jamming, attack on ground stations, concealment and the like. Calamitous effects of attack on one's own satellites can be avoided by prudent planning, replacement capabilities, backup systems, and so forth.

Can one prove with certainty that space weapons will lead to disaster rather than to improved security or that global defense against ballistic missiles is *impossible*? If not, how do we dare deny ourselves these options? Are we joining the ranks of those who denied the possibility of airplane flight or of an ICBM bearing a nuclear warhead?

Over the years we have considered three possibilities concerning space weapons:

- no additional arms control measures in space;
- banning all military activities in space; and
- banning weapons in space.

In our opinion, the combination of a program for nullifying nuclear weapons by space means and the necessity for satellite components of any such system is a most severe threat to U.S. national security. That combination can convert the present world (with the universally acknowledged ability to destroy the Soviet Union, the United States, their allies and perhaps much of human life in the Northern Hemisphere) from a stable confrontation to an inherently unstable one, needing only the smallest spark to bring on a nuclear conflagration. This instability can arise from appearances—it does not need real capability. Pointing a toy handgun at a police officer is as good a way to be shot by the officer's partner as pointing a real gun. A supposedly effective ABM system depending on space elements could be countered by space mines within lethal range of the satellites. An attempt to prevent such vulnerability could be enforced in the early stages of deployment only by the destruction of the other side's missiles while it was launching space mines.

Banning all *military* activity from space seems neither necessary or desirable, since "military" applies to communication, navigation, administration, supply and other normal functions when performed for military personnel. The matter has also been discussed in the U.N. Committee on Disarmament, and even to that body a total ban on military activities seems neither practical nor desirable. Uninhibited ASAT development, in a protracted drive for space-supported defense (ICBM-killers), appears likely to lead to instability and attack even in peacetime.

During the U.S.-Soviet ASAT negotiations of 1978–1979, many options were considered, including the possession by

each side of a single type of ASAT system, the provision of sanctuary to satellites above a certain altitude, a total ban on damage to or destruction of satellites and the like. The negotiations were not resumed after the Soviet invasion of Afghanistan, but in 1981 the Soviet Union introduced into the United Nations a draft "treaty on the prohibition of the stationing of weapons of any kind in outer space." Unfortunately, that treaty appeared to convey protection only to those "space objects . . . placed in orbit in strict accordance with . . . this treaty" and to sanction the use of force against other satellites. Furthermore, the 1981 Soviet draft covered only space-based systems, thus permitting current Soviet and U.S. ASATs.

In September 1982, at a Senate Foreign Relations Committee hearing on the militarization of space, Richard Garwin testified that the 1981 Soviet draft should not be ignored and that if the U.S. government did not reply with a draft which would serve U.S. purposes, then even a private group might forward the cause of U.S. security by doing so. In May 1983 Admiral Noel Gayler, Kurt Gottfried and Garwin testified to the same committee in support of "A Treaty Limiting Antisatellite Weapons," which we had helped prepare, with the support of the Union of Concerned Scientists (see page 10S). The Soviet Union followed in August by introducing into the United Nations a new draft treaty "On the Prohibition of the Use of Force in Outer Space and from Outer Space with Regard to Earth" (see page 11S). Aside from what seems to be a totally unnecessary and unacceptable provision "not to test, nor use, for military, including counter-satellite ends, any manned spaceships," this 1983 Soviet draft provides a very suitable basis for early agreement.

Recommendations

The greatest urgency is to negotiate quickly a ban on weapons in space, starting with the Soviet draft of 1983, because it is presumably largely acceptable to the Soviet Union. Although it might be argued that in principle a better agreement could be obtained by going into more detail and taking longer to analyze and to negotiate, the situation is not static and the benefits of an early, all-encompassing agreement far outweigh any advantages which might follow from more detailed consideration.

The United States of course should take unilateral steps to make its military capabilities effective and robust against violation of such an agreement. This means, for example, backup communication and navigation systems for theater war. The United States should also (and the Soviet Union probably will) develop means for reducing the effectiveness of opposing satellite-based systems for support of conventional or nuclear military operations, short of putting weapons into space or damaging or destroying satellites. These measures could include jamming of communication links, decoys to deceive radar satellites and preparations for attack on ground stations not as safeguards necessitated by an ASAT ban, but as prudent self-interest.

An ASAT ban like that of our May 1983 draft or the Soviet draft of August 1983 cannot be expected to protect satellites in an all-out nuclear war. Nor can one realistically (or verifiably) eliminate residual threats to satellites, such as the nuclear-armed Soviet ABM system deployed at Moscow since before 1972 and permitted by the 1972 ABM Treaty. It would not eliminate the possibility of satellite destruction by a nuclear-armed ICBM launched to attack a "point-in-space" rather than a ground target. On the other hand, all the United States would renounce under an ASAT ban would be attack on Soviet satellites (and those of other countries) and some other roles for space weapons in war, (for example, attack on high-flying aircraft) which could better be performed by sensors in space and weapons launched from air or ground.

Regarding the denial of space for emplacing weapons for global defense, the proposed agreement would simply reinforce the constraints of the ABM Treaty, which President Reagan said the United States would observe in any case. We could and should continue to do theoretical and laboratory research on potential defensive systems, and a five-year review provision of a treaty of indefinite duration (as in the case of the ABM Treaty) would provide the opportunity to adapt the Treaty to technical and political realities and opportunities as they arise. □

Glossary of technical terms

geosynchronous orbit (GEO)—orbit in which a satellite remains stationary over a given area on Earth
hard X ray—one having short wavelength and high penetrating power
joule—unit of work or energy equivalent to 10^7 ergs or about 0.7375 foot-pounds or 0.2390 gram calories
kilo-—1,000
low-earth orbit (LEO)—orbit 100 to 500 kilometers in height
micro-—one-millionth
micron—one-millionth of a meter or one-thousandth of a millimeter
optical guidance system—active: emits energy which is reflected from an object; this reflected energy is then used for targeting; passive: senses energy from an object for targeting
plasma—ionized gas containing about equal numbers of positive ions and negative electrons. Differs from ordinary gas in being a good conductor of electricity and being affected by a magnetic field
radian—angular measurement equal to the angle at the center of a circle subtended by an arc equal in length to the radius of the circle; about 57.29 degrees
soft X ray—one having comparatively long wavelength and poor penetrating power
watt—power which produces energy at the rate of one joule per second; 1/746 horsepower

A treaty limiting anti-satellite weapons

Draft treaty presented to the U.S. Senate Foreign Relations Committee in May 1983 by the Union of Concerned Scientists et al.

Article I

Each Party undertakes not to destroy, damage, render inoperable or change the flight trajectory of space objects of other States.

Article II

1. Each Party undertakes not to place in orbit around the Earth weapons for destroying, damaging, rendering inoperable, or changing the flight trajectory of space objects, or for damaging objects in the atmosphere or on the ground.

2. Each Party undertakes not to install such weapons on celestial bodies, or station such weapons in outer space in any other manner.

3. Each Party undertakes not to test such weapons in space or against space objects.

Article III

1. For the purpose of providing assurance of compliance with the provisions of this treaty, each Party shall use national technical means of verification at its disposal in a manner consistent with generally recognized principles of international law.

2. Verification by national technical means shall be supplemented, as appropriate, by such cooperative measures for contributing to the effectiveness of verification by national technical means as the Parties shall agree upon in the Standing Consultative Commission.

3. Each Party undertakes not to interfere with the national technical means of verification of the other Party operating in accordance with paragraph 1 of this Article.

4. Each Party undertakes not to use deliberate concealment measures which impede verification by national technical means of compliance with this treaty.

Article IV

1. To promote the objectives and implementation of the provisions of this treaty, the Parties shall use the Standing Consultative Commission, established by the Memorandum of Understanding Between the Government of the United States of America and the Government of the Union of Soviet Socialist Republics regarding the Establishment of a Standing Consultative Commission of December 21, 1972.

2. Within the framework of the Standing Consultative Commission, with respect to this treaty, the Parties will:

a) consider questions concerning compliance with the obligations assumed and related situations which may be considered ambiguous;

b) provide on a voluntary basis such information as either Party considers necessary to assure confidence in compliance with the obligations assumed;

c) consider questions involving unintended interference with national technical means of verification, and questions involving unintended impeding of verification by national technical means of compliance with the provisions of this treaty;

d) consider, as appropriate, cooperative measures contributing to the effectiveness of verification by national technical means;

e) consider possible changes in the strategic situation which have a bearing on the provisions of this treaty, including the activities of other States;

f) consider, as appropriate, possible proposals for further increasing the viability of this treaty, including proposals for amendments in accordance with the provisions of this treaty.

Article V

The Parties undertake to begin, promptly after the entry into force of this treaty, active negotiations with the objective of achieving, as soon as possible, agreement on further measures for the limitation and reduction of weapons subject to limitation in Article II of this treaty.

Article VI

In order to ensure the viability and effectiveness of this treaty, each Party undertakes not to circumvent the provisions of this treaty, through any other State or States, in any other manner.

Article VII

Each party undertakes not to assume any international obligation which would conflict with this treaty.

Article VIII

1. Each Party may propose amendments to this treaty.

2. Agreed amendments shall enter into force in accordance with the procedures governing the entry into force of this treaty.

Article IX

This treaty shall be of unlimited duration.

Article X

Each Party shall, in exercising its national sovereignty, have the right to withdraw from this treaty if it decides that extraordinary events related to the subject matter of this treaty have jeopardized its supreme interests. It shall give notice of its decisions to the other Party six months prior to withdrawal from the treaty. Such notice shall include a statement of the extraordinary events the notifying Party regards as having jeopardized its supreme interests.

Article XI

1. This treaty shall be subject to ratification in accordance with the constitutional procedures of each Party.

2. This treaty shall enter into force on the day of the exchange of instruments of ratification.

Article XII

1. Done in two copies, each in the English and Russian languages, both texts being equally authentic.

2. This treaty shall be registered pursuant to Article 102 of the Charter of the United Nations.

Treaty on the prohibition of the use of force in outer space and from space against the Earth

Presented by the Soviet Union to the General Assembly of the United Nations in August 1983

Article 1

It is prohibited to resort to the use or threat of force in outer space and the atmosphere and on the Earth through the utilization, as instruments of destruction, of space objects in orbit around the Earth, on celestial bodies or stationed in space in any other manner.

It is further prohibited to resort to the use or threat of force against space objects in orbit around the Earth, on celestial bodies or stationed in outer space in any other manner.

Article 2

In accordance with the provisions of article 1, States Parties to this treaty undertake:

1. Not to test or deploy by placing in orbit around the Earth or stationing on celestial bodies or in any other manner any space-based weapons for the destruction of objects on the Earth, in the atmosphere or in outer space.
2. Not to utilize space objects in orbit around the Earth, on celestial bodies or stationed in outer space in any other manner as means to destroy any targets on the Earth, in the atmosphere or in outer space.
3. Not to destroy, damage, disturb the normal functioning or change the flight trajectory of space objects of other States.
4. Not to test or create new anti-satellite systems and to destroy any anti-satellite systems that they may already have.
5. Not to test or use manned spacecraft for military, including anti-satellite, purposes.

Article 3

The States Parties to this treaty agree not to assist, encourage or induce any State, group of States, international organization or natural or legal person to engage in activities prohibited by this treaty.

Article 4

1. For the purpose of providing assurance of compliance with the provisions of this treaty, each State Party shall use the national technical means of verification at its disposal in a manner consistent with generally recognized principles of international law.
2. Each State Party undertakes not to interfere with the national technical means of verification of other States Parties operating in accordance with paragraph 1 of this article.

Article 5

1. The States Parties to this treaty undertake to consult and co-operate with each other in solving any problems that may arise in connection with the objectives of the treaty or its implementation.
2. Consultations and co-operation as provided in paragraph 1 of this article may also be undertaken by having recourse to appropriate international procedures within the United Nations and in accordance with its Charter. Such recourse may include utilization of the services of the Consultative Committee of States Parties to the treaty.
3. The Consultative Committee of States Parties to the treaty shall be convened by the depositary within one month after the receipt of a request from any State Party to this treaty. Any State may nominate a representative to serve on the Committee.

Article 6

Each State Party to this treaty undertakes to adopt such internal measures as it may deem necessary to fulfill its constitutional requirements in order to prohibit or prevent the carrying out of any activity contrary to the provisions of this treaty in any place whatever under its jurisdiction or control.

Article 7

Nothing in this treaty shall affect the rights and obligations of States under the Charter of the United Nations.

Article 8

Any dispute which may arise in connection with the implementation of this treaty shall be settled exclusively by peaceful means through recourse to the procedures provided for in the Charter of the United Nations.

Article 9

This treaty shall be of unlimited duration.

Article 10

1. This treaty shall be open to all States for signature at United Nations Headquarters in New York. Any State which does not sign this treaty before its entry into force in accordance with paragraph 3 of this article may accede to it at any time.
2. This treaty shall be subject to ratification by signatory States. Instruments of ratification and accession shall be deposited with the Secretary-General of the United Nations.
3. This treaty shall enter into force between the States which have deposited instruments of ratification upon the deposit with the Secretary-General of the United Nations of the fifth instrument of ratification, provided that such instruments have been deposited by the Union of Soviet Socialist Republics and the United States of America.
4. For States whose instruments of ratification or accession are deposited after the entry into force of this treaty, it shall enter into force on the date of the deposit of their instruments of ratification or accession.
5. The Secretary-General of the United Nations shall promptly inform all signatory and acceding States of the date of each signature, the date of deposit of each instrument of ratification or accession, the date of entry into force of this treaty as well as other notices.

Article 11

This treaty, of which the Arabic, Chinese, English, French, Russian and Spanish texts are equally authentic, shall be deposited with the Secretary-General of the United Nations, who shall send duly certified copies thereof to the Governments of the signatory and acceding States.

Effect on strategic stability

by Yevgeny P. Velikhov

TWO DISTINCT DIRECTIONS in space militarization have recently emerged—the creation of anti-satellite weapons (ASAT) and the development of space-based anti-missile systems (SBAMS). These two directions, I believe, are closely meshed with the problems of strategic balance and stability, and with prospects for substantial nuclear arms reductions.

With regard to anti-satellite weapons my impression is that their proponents in the United States have not adequately considered the real functions such weapons could have in the overall strategic context.

American scientists have explained to my colleagues and me that the advocates of U.S. anti-satellite systems push their plans through only because the Soviet Union is rapidly developing such systems. But the Soviet leadership has authoritatively and concretely declared that it unilaterally assumes the obligation not to test and deploy anti-satellite systems, and that it proposes to reach an agreement with all countries not to acquire new anti-satellite systems and to eliminate all the existing systems. Thus, the argument used by supporters of the U.S. ASAT system becomes completely groundless and unpersuasive.

As for the strategic consequences of the deployment of these weapons, if they were used, the side attacked would have to consider the hypothetical massive use of offensive nuclear weapons that could follow.

An attempt to destroy the opponent's satellites or even to "blind" them for some period of time can be justifiably regarded as the first step in initiating unlimited nuclear war. Destruction of the satellites would give every reason to the attacked side to retaliate immediately, destroying all possible enemy targets, without waiting for a nuclear attack on their own, launching complexes and other military and civil targets.

The creation of a constant threat to satellites through the deployment of an anti-satellite system will impair the prospects of reaching agreements on a freeze of nuclear weapons, deep reductions, and confidence in their verification. Even without this threat the verification problem is used in the United States as an argument to frustrate existing agreements.

Research by the Committee of Soviet Scientists on the problem of a freeze is nearing completion. But preliminary results show that existing national technical means of verification, based on the use of appropriate equipment on satellites, are good enough to verify agreements on the freeze of a wide range of weapon systems at various stages of development. In this connection I should emphasize that we must strengthen and not undermine confidence in national technical means. Invulnerability of satellites used for verification purposes is an important stabilizing politico-psychological factor and an indispensable technical part of a freeze agreement as well as of START and other negotiations.

In light of the decision by the U.S. side to reject a ban on ASAT weapons, we have the full right to doubt the seriousness of U.S. intentions to reach an agreement at the START talks.

It should be added that any hope of getting significant unilateral advantage from a strategic or political-military point of view is absolutely groundless. There are those who have great expectations for the technical sophistication of the U.S. anti-satellite system. In my view, however, judging by the record of the postwar decades, the United States has no chance of creating a tangible breakthrough in qualitative weapon-systems characteristics which would leave the Soviet Union far behind. And even if one side achieves short-term qualitative advantages, the other side can compensate by greater quantity.

RESEARCH AND development of space-based anti-missile systems as basic elements of widescale strategic "defense" have had a very powerful political and monetary impetus. But to my mind, those who insist on this kind of system with its attendant huge expenditures—claiming that it is the way to eliminate the threat of nuclear war to the United States and the whole world—do not see the whole complex of scientific and technological problems and possible consequences affecting strategic stability and international security.

A special research project on this problem was recently completed by the Committee of Soviet Scientists' Working Group headed by R. Sagdeev and A. Kokoshin.[4] The study gave particular attention to the potential weapon systems that could be created on the principle of directed energy transfer—weapon systems which are the subject of active debate in the United States today. Several types of energy sources at different stages of technical development were considered as possible components for a directed energy weapons system—lasers working in infrared, visible or ultraviolet range; X-ray lasers pumped by nuclear explosion; high-energy particle accelerators; UHF (ultra-high frequency) or microwave generators.

According to published information the hydrogen-fluoride infrared lasers seem to be at the most advanced stages of technical development in the United States. It is assumed that the prototype space-based anti-missile systems would include a five-megawatt laser and four-meter diameter mirror. Such a system could presumably be developed within

Yevgeny P. Velikhov, a vice-president of the Soviet Academy of Sciences and deputy director of the Kurchatov Institute of Atomic Energy in Moscow, is also chairman of the Committee of Soviet Scientists for Peace Against Nuclear War.

eight to ten years. According to the estimates by the Sagdeev-Kokoshin group, a space-based anti-missile system having approximately 18 orbital stations would be capable of destroying only about 15 ICBMs in 100 seconds (assuming massive launch), or up to 100 ICBMs in 15 minutes (assuming time-scattered launch). It is assumed that the launch sites would be within the range of two orbital stations simultaneously. A technically feasible improvement—some 10 to 20 kilojoules per square centimeter—of resistance to laser energy would make such a system incapable of destroying ICBMs.

The Working Group's estimates indicate further that development of a SBAMS effective enough to destroy 1,000 ICBMs in 100 seconds would require an increase in mirror diameter from four to 15 meters; in laser power capacity from five to 60 megawatts; and in fuel capacity from 45 to about 700 or 800 metric tons. Obviously, development of systems with these capabilities is currently beyond existing technical possibilities; considerably more intense research and development, on a wider scale, would be needed.

Still another requirement would be the development of a new heavy space launcher, much larger than the current space shuttle. Three to four times greater laser power capacity and two to three times larger mirror diameter would also be required if ICBM resistance to laser beams were further improved.

According to Western sources the development of neutral particle-beam accelerators which could be used in space-based anti-missile systems is not as advanced as the development of high-power lasers, and their construction would take considerable technical effort. The same situation obtains for the UHF generator-based system. Serious technical criticism could also apply to the possible uses of X-ray lasers.

The estimates mentioned above for large-scale space-based anti-missile systems using chemical lasers—up to 60 megawatts in power and with 15-meter mirror diameter—are related to a hypothetical "ideal" full-scale system, supposedly 100 percent reliable both technically and operationally. Obviously real SBAMS would not be absolutely reliable and would need backup duplicating components. The orbital stations themselves might have to be duplicated to compensate for technical unreliability. Operational unreliability would require the development of multi-layer SBAMS (having, in particular, traditional anti-missiles based on land or in space as an additional component). This has been under active consideration in the United States in recent years.

Even high operational reliability cannot guarantee absolute protection. For instance, a three-layer system, with 90 percent operational reliability for every layer, if used against 1,000 ICBMs with, say, 10 warheads each, would be expected to let through some 10 warheads. These could inflict tremendous damage.

Construction of effective SBAMS might require deployment of about 50 such platforms into polar orbits. Deploying fewer systems, in geosynchronous orbit, would take a bigger investment because of higher costs associated with such orbits, additional requirements in laser power, focusing, accuracy and so on.

The total cost of such systems, according to the Sagdeev-Kokoshin Working Group, would roughly amount to $400 billion. But that would be just one layer, which, as we have seen, would not be sufficient due to the need for redundancy.

THERE ARE SOUND reasons to believe that effective countermeasures could be taken more easily. According to the Group, such countermeasures would also be considerably cheaper—their cost amounting only to one or two percent of the total investment required for building a full-scale space-based anti-missile system. This cost ratio would probably also be preserved for the higher power capacity levels of the system and a consequent anti-system.

At a particular time, the side preparing a first strike can easily create a wide "window" among the battle platforms orbiting the Earth and use it for massive ICBM or SLBM attack. Thus the vulnerability of the system to counter-measures is the main factor leading to the view that such a system is intended for assuring a successful first strike. A strike could be launched against both offensive forces and anti-space ballistic missile defense systems of the other side, with the hope of reducing their ability to retaliate, while protecting itself with the space-based systems from such retaliation.

> "All attempts at gaining military superiority over the U.S.S.R. are futile. The Soviet Union will never allow them to succeed. It will never be caught defenseless by any threat.
>
> Let there be no mistake about this in Washington. It is time they stopped devising one option after another in search of the best ways of unleashing nuclear war in the hope of winning it. Engaging in this is not just irresponsible, it is insane."
>
> —*Yury Andropov*
>
> Replying to President Reagan's Star Wars speech in an interview in Pravda, March 27, 1983.

All this allows the conclusion that the deployment of even "ideal" systems would not assume (its proponents claim) a shift from the MAD (mutual assured destruction) posture—from the "strategy of deterrence based upon the threat of retaliation" to the defense-oriented strategy based on the ability to assure protection from a full-scale ICBM attack. On the contrary, the deployment of such a system would significantly complicate the maintenance of deterrence, making it highly unstable, for it would stimulate the illusion of advantages (damage limitation and even a chance for surviving nuclear war) associated with a first strike.

There are good reasons to believe that if both sides possessed space-based systems the destabilizing effect would be much greater than if such systems were available to only one side. In the context of strategic logic (without consider-

ing psychological and political aspects) this thinking arises from the fact that if both sides had these systems their impetus for a preemptive first strike would be greater, since each side could hope to secure an advantage by striking first.

As the Committee of Soviet Scientists noted, the U.S. refusal to undertake a no-first-use obligation and U.S. strategic programs aimed at acquiring a first-strike potential are additional reasons for considering prospective U.S. space-based systems as part of a first-strike strategy. An important element in implementing this policy is the deployment of U.S. medium-range missiles (particularly Pershing II) in Western Europe, aimed at "decapitation."

In contrast, the Soviet side, bearing in mind the tremendous importance of strengthening strategic stability in the atmosphere of growing political-military tensions, in June 1982 undertook the unilateral obligation not to use nuclear weapons first. This position was afterwards confirmed more than once by the highest Soviet government and military leaders. This obligation is not only political and diplomatic in character; it has become an integral part of Soviet military training and entails additional scientific and technological decisions.

In line with this commitment much more attention is paid to the goal of preventing non-nuclear conflict from growing into nuclear. Thus, more rigid limits have been set for troop training and command, and stricter controls organized to make unauthorized launch of tactical or strategic nuclear weapons impossible.

Besides the likelihood of countermeasures to space-based anti-missile systems—for example, hardening of ICBM boosters—the Sagdeev-Kokoshin Working Group thinks it highly probable that there will emerge a weapon intended to neutralize these systems (counter- "anti-SBAMS"). I agree with those specialists who have concluded that during the development and deployment stages of SBAMS, penetration capabilities of strategic offensive forces, including their qualitative improvement, will be modernized more rapidly.

The development of SBAMS could stimulate an increase in the arsenals of strategic delivery vehicles and nuclear warheads, for example, strategic cruise missiles, including sea- and ground-launched cruise missiles. Cruise missile deployment is extremely difficult if not impossible to verify by national technical means, and U.S. experts who suppose that the United States can retain a monopoly on strategic cruise missiles are badly misled.

If tests of the space-based systems were to begin, to say nothing of their actual deployment, the permanent ABM Treaty signed on May 26, 1972, would be threatened. Item 1, Article V of this Treaty postulates: "Each Party undertakes not to develop, test or deploy ABM systems or components which are sea-based, air-based, space-based or mobile land-based."

It is hard to overestimate the importance of this U.S.-Soviet Treaty today for it remains the only ratified and acting agreement in the area of strategic arms limitation.

THE PRESENCE of tested and deployed elements of space-based systems, even of limited scope, could considerably hinder the progress of negotiations on strategic arms limitations and limitations of nuclear weapons in general.

Such an unfortunate result would be inevitable. The introduction of a qualitatively new component in the strategic arsenal of one or both sides would confuse the existing assessments of strategic balances and bring up additional complications in the comparison of forces. The development of space-based anti-missile systems is likely to go in different ways in the two countries as has been true of the strategic arms race. Such differences would increase the asymmetries in the strategic potentials of our two countries—thus making comparisons even more difficult. These asymmetries could become increasingly significant in the face of deployment of potential anti-SBAMS systems and countersystems.

After these systems were deployed, U.S.-Soviet strategic arms limitation and reduction agreements would be more complex and correspondingly more difficult to understand on the part of the public, which plays an increasingly important role in solving the problems of war and peace.

With regard to international political consequences the deployment of space-based systems cannot be ignored. They would inevitably become a serious obstacle for U.S.-Soviet cooperation in the peaceful uses of space. Yet the potential value of such cooperation is important from economic, scientific and technological points of view, because of the many mutually complementary characteristics of the Soviet and U.S. space programs. Cooperation in this area could be a very positive factor, politically and psychologically, in improving U.S.-Soviet relations in general, and in strengthening the confidence between the peoples and the leaders of the two great powers.

THE POTENTIAL impact of a large-scale space-based anti-missile program on the strategic balance would be to substantially increase both the risk of a preemptive strike and the likelihood of wrong and fatal decisions in crises. Hence even if rough parity in strategic forces were preserved, strategic stability would be seriously undermined.

Deployment of strategic "defensive systems" would definitely trigger a chain reaction in the development of new weapon systems. That would confuse the strategic balance to an unprecedented degree and increase the uncertainty in political-military decision-making.

In view of the existing dialectical relationship between strategic offensive and defensive systems, even the possibility of building SBAMS would seriously undermine the possibility of future U.S.-Soviet (and perhaps multilateral) agreements on strategic arms limitation and reduction talks, and thus the prospects for strengthening strategic stability.

Abrogation of the ABM Treaty would in turn undoubtedly lessen chances for reaching mutually beneficial strategic arms limitation and reduction agreements in the near future. The stabilizing regime created by the 1972 ABM Treaty could be strengthened significantly by agreements on the non-deployment in space of any weapons and the non-use of force in space. These would include a ban on the use of force from space against the Earth, as well as a ban on anti-satellite weapons.

Vast resources would be required for construction of a space-based anti-missile system, to say nothing of the scientific and technological capital already devoted to this enterprise. These funds and efforts could be effectively diverted to large-scale international bilateral and national programs of a peaceful nature. If this were to happen, that part of U.S. industry which would have been employed to develop the space system could effectively be engaged in such peaceful projects.

It was the unanimous view of the Committee of Soviet Scientists that programs of cooperation in this field could substantially contribute to and expedite the solution of increasingly acute global problems such as economic development, energy, resources and ecology. They could also create a basis for successful space exploration by future generations of the Earth's inhabitants. □

**Political-Military Implications of Prospective American Space-Based Anti-Missile System*, report issued by the Committee of Soviet Scientists for Peace Against the Nuclear Threat (Moscow: 1983).

R. Sagdeev heads the Institute of Space Research of the Soviet Academy of Sciences. He serves as vice-chairman of the Committee of Soviet Scientists. A. Kokoshin is head of the political-military department in the Institute of U.S. and Canadian Studies of the Soviet Academy of Sciences and is vice-chairman of the Committee of Soviet Scientists. The Working Group included members of the Institutes of Space Research, of World Economy and International Relations, and of U.S. and Canadian Studies: A. Arbatov, A. Vasiliev, R. Nazirov, O. Prilutsky, R. Rodin and S. Rodionov.

Averting a Brobdingnagian Skeet Shoot

Arms Control Measures for Anti-Satellite Weapons

Donald L. Hafner

. . . Imagination can figure nothing so grand, so surprising, and so astonishing. It looked as if ten thousand flashes of lightning were darting at the same time from every corner of the sky. . .

—Gulliver's Travels, *A Voyage To Brobdingnag*

On June 8, 1978, American and Soviet negotiators seated themselves at the bargaining table in Helsinki and convened the first round of talks on arms control measures for anti-satellite (ASAT) weapons. On December 24, 1979, while preparations were underway for a fourth round of ASAT talks, the Soviets invaded Afghanistan, making it impossible to continue "business as usual" on arms control with the Soviet Union.

No one would counsel the resumption of ASAT negotiations if it were contrary to U.S. interests in light of recent Soviet behavior. However, the problems which brought the United States to the negotiating table in the first place have not disappeared. They promise only to get worse. The United States therefore still has a compelling reason for exploring effective and verifiable arms control measures for space weapons: at a time when satellites are becoming progressively vital to our national security, we do not have any other means for reliably protecting our satellites against future ASAT weaponry.

The opportunity that the United States now has before it to place constraints upon arms competition in the broad reaches of outer space is ripe but perishable. The ASAT technologies currently available to the United States and the Soviet Union are crude but suggestive. Should the momentum of ASAT programs increase, it is evident that the two sides will provoke each other into expending billions of dollars, all in preparation for a "Brobdingnagian skeet shoot"[1] from which neither side is likely to derive a net advan-

1. This colorful image, recalling the land of giants in *Gulliver's Travels*, was offered by Paul Warnke, chief U.S. negotiator at the first round of ASAT talks.

Donald L. Hafner is an Associate Professor of Political Science at Boston College. During 1977–78, while serving with the Arms Control and Disarmament Agency, Professor Hafner was an advisor to the SALT delegation in Geneva and an analyst with the NSC ASAT Working Group.

tage in security. The ASAT negotiations themselves retarded this momentum, because the Soviets voluntarily suspended their ASAT testing program while the talks were in progress. But with the negotiations now in abeyance, the Soviets resumed testing on April 18, 1980, with the launch of Cosmos 1174. Moreover, a U.S. intelligence report in May asserted that there is "evidence of a Soviet project to develop a space-based laser weapon that we believe may have an anti-satellite application. . . . such weapons may be available for operational use in the mid- to the late 1980s." Clearly there is an urgency to exploring arms control prospects.

Since this novel area of arms control touches on issues not widely discussed in public, it is well to review the matters at stake and to suggest what an effective ASAT agreement should contain.

Anti-Satellite Weapons: Present and Future Technology

At an increasing rate, satellites are being exploited by the United States to perform a variety of civil and military tasks, including communication, meteorology, navigation, surveillance and reconnaissance, warning of military attack, and monitoring of arms control agreements. As reusable launch boosters such as the Space Shuttle reduce the cost of placing satellites in orbit and make sustained manned operations feasible, the list of tasks will expand.

At present, the United States and the Soviet Union together have about 150 active satellites in orbit.[2] By the mid-1980s that number will rise to around 200. The total investment represented by these satellites cannot be fixed, because neither side will acknowledge the precise number or cost of military and intelligence satellites. Only rough yardsticks are available. The U.S. Defense Department, for instance, is establishing a set of complex communications networks (FLTSATCOM, AFSATCOM, DSCS, etc.), with satellites incorporating costly protective features to guard against such threats as electronic jamming. Funding for development, procurement, and launching of these military systems has been $200–300 million annually for the past several years and will continue at these levels into the 1980s. It would not be surprising, therefore, if the satellites currently maintained in orbit by the United States or the Soviet Union represented $5–10 billion worth of investment—a figure that begins to rival the cost of major strategic weapons systems, such as Trident.

---

2. The total number of no-longer-functioning satellites still in orbit is much greater, and the total number of objects in orbit, including debris, is larger still.

The value of satellites, however, is not properly weighed in terms of their investment costs alone. Our growing dependence upon satellites for carrying out a variety of vital missions is a more pertinent index of their importance—and in turn, of the importance of protecting them through arms control measures. This dependence varies from case to case. In many instances, the missions performed by satellites were previously carried out by earth-based facilities: in the communications area, for instance, by undersea cables and radio transmitters; in the navigation area, by such radio beacon systems as LORAN. Satellites are now preferred for these missions because they can perform with higher efficiencies. Many of the ground-based networks that they replaced have subsequently been dismantled. Nonetheless, satellites may not be indispensible for these tasks. If we fail to reach an ASAT agreement which protects satellites, the United States could presumably revert to ground-based systems, though this would mean higher costs, continued dependence upon overseas installations, and a U.S. military presence in foreign nations that might be difficult to ensure.

For certain other missions, however, satellites provide unique capabilities that cannot readily be duplicated by ground-based systems. Overhead photographic surveillance, so crucial for military intelligence and crisis monitoring during regional conflicts, is an important example. It would be feasible technically to carry out such missions by less exotic means than satellites—by U-2s for instance. But the political obstacles to securing broad consent among nations for such surveillance overflights are so overwhelming that, as a practical matter, satellites are indispensable. Hence, it is a matter of concern that satellites are quite vulnerable to an array of techniques for attacking them or interfering with their missions.

These vulnerabilities are a problem for virtually any satellite, not just those belonging to military or intelligence agencies. No attacker is going to grant free passage to a militarily useful communications or meteorology satellite, simply because it carries the emblem of a civilian agency or international corporation. An article in the Soviet press published on the eve of the first ASAT talks for instance, offered a well-informed discussion of the interchangeability of U.S. and NATO satellites for military communications purposes.[3] So the protection of a vast number and variety of satellites is at issue here.

---

3. Col. A, Zhovanki, "Long-Range Communications: Problems and Solutions" *Krasnaya Zvezda*, June 7, 1978. Under the Defense Department's GAPFILLER program in the late 1970s, for example, the U.S. Navy met its Fleet Satellite Communications requirements by leasing channels on the civilian MARISAT satellites.

Until recently, the United States devoted relatively little effort to diminishing the vulnerability of its satellites. Since the costs of launching a complex satellite were typically above $20 million and rose as the weight of the satellite increased, it was penny-wise to cram every available ounce with equipment and to omit survivability features (such as armor plating, anti-jamming devices, evasive maneuvering capabilities, shielding against lasers, etc.). Some intrinsic "hardness" against attacks or interference occurred as an incidental benefit of general efforts to make satellites more durable in the hostile environment of space. But far more extensive and costly defensive measures would be necessary, if the Soviets incorporate the best technology into ASAT weapons—and even then the protection would be marginal at best.

As matters stand now, the best technology has not yet been applied to ASAT weapons. There is at the present time a breathing spell during which the future can still be shaped. This has not been due to a lack of imagination or foresight on the part of ASAT designers. Schemes for shooting down satellites predate satellites. The first study of ASAT systems commissioned by the U.S. Air Force was undertaken in the mid-1950s, before the Soviets had launched Sputnik. Even at that time, it was evident that a variety of techniques for attacking satellites were conceivable. And since ASAT weapons come in great variety, an ASAT arms control agreement must be couched in broad terms to encompass all possibilities.

The earliest U.S. studies of ASAT systems focused on two basic approaches: either a "killer satellite" interceptor that would be placed in orbit and then maneuvered to its target, or a direct-ascent interceptor that would rise from the earth and promptly intercept the target when it passed overhead. With either technique, the target could be destroyed by a nuclear warhead or by some non-nuclear means. A nuclear warhead would have a kill radius of tens or even hundreds of miles, depending upon the intrinsic hardness of the target to nuclear radiation. But the drawbacks are that the radiation would also damage friendly satellites at great distances from the enemy target, and by breaching the nuclear threshold, such a warhead could escalate a conventional confrontation to higher levels of violence. Non-nuclear warheads avoid these problems, but their kill radii are also smaller, and so they require more precise interceptor accuracy and timing in order to get the warhead close enough to the target to do damage.

"Killer satellite" interceptors were the earliest means devised for getting the accuracy needed with non-nuclear warheads. Launched so that it has an orbit and speed roughly comparable to the enemy target, a "co-orbital" interceptor can then make last-minute maneuvers while closing on the target

at relatively low speeds. The interceptor must guide itself during the last moments of attack, so it requires a homing system, e.g., an active search radar or optical scanner. (Guidance from the ground would be insufficiently precise or timely for the last phase of engagement.) If the maneuvering capability of the interceptor can be made great enough, and if the detection range of the homing device is greatly extended, then the relatively low closing speeds provided by a co-orbital approach would not be necessary at all. The interceptor could instead be boosted in direct-ascent from its ground site to detect, pursue, and destroy a target passing overhead. Such a system could be highly effective against satellites in lower orbits (that is, those below about 1,000–2,000 nautical miles), because its swift approach would give the target little warning or time for evasive measures. In the past, however, technology has not been available to meet these more rigorous maneuvering or homing requirements for non-nuclear interceptors. Schemes for direct-ascent systems relied instead upon nuclear warheads that did not require great accuracy, but which had the drawbacks noted above.

The first U.S. Air Force anti-satellite program (SAINT) was a co-orbital interceptor that was to inspect and destroy targets. The project appears to have been a stalking horse for other Air Force space projects, rather than a fully-conceived ASAT effort. In any case, SAINT never advanced beyond the research and development phase and was cancelled in 1962. The U.S. ASAT mission then became an orphan, temporarily given shelter under the Army's ABM program by those who recognized that, in principle, the ABM test facilities on Kwajalein Island in the Pacific could also work reasonably well as a nuclear-armed direct-ascent ASAT system against low altitude satellites. In 1964, prodded by concerns over a Soviet orbital bombing threat (FOBS and MOBS), the Air Force resumed ASAT missions by establishing nuclear-armed Thor IRBMs on Johnston Island in the Pacific. The location was appropriate for intercepting Soviet satellites on their initial orbital passes, but the THORS were costly and clumsy instruments. The facility was closed down in the early 1970s.

The United States has now reverted to non-nuclear direct-ascent ASAT schemes, derived from ABM research. Contracts were awarded in 1977 to the Vought Corporation to develop a Miniature Homing Vehicle (MHV), weighing 34 pounds, to be launched from the ground or from an aircraft on a relatively inexpensive booster.[4] For FY 1980, the Defense Department

4. The favored scheme is an air-launch using a modified SRAM as booster; cost estimate for the booster alone, $1 million each.

budget request for R&D on this MHV system was $63 million. Since the MHV interceptor is designed to destroy its target by ramming it, very high accuracies (near-zero CEP against targets closing at speeds greater than 17,000 mph) will have to be achieved. Comparable marvels have been produced by American technology in the past, but there are knowledgeable critics whose doubts about the feasibility of the MHV will not be laid to rest until flight tests actually succeed against orbiting targets. The first space tests of the MHV will reportedly not occur until 1982. If the United States were instead to pursue a less exotic co-orbital interceptor, using off-the-shelf hardware, a rudimentary ASAT system could probably be demonstrated in short order. For the moment, however, the United States does not have a weapon system specifically dedicated to the ASAT mission, despite expenditures of several hundred million dollars on various schemes over the past twenty years.

The Soviets have undoubtedly also explored a variety of ASAT approaches. In 1964, a PKO division[5] of the Soviet PVO-Strany strategic defense forces was established, charged with the mission of "destroying the enemy's cosmic means of fighting." By 1967, preliminary tests of an ASAT system had begun. The system is based on a co-orbital interceptor that destroys its target with a non-nuclear warhead after first maneuvering to cross the path of the target. In the early 1970s, the Soviets ceased flight tests of the interceptor, and then resumed them in 1976, with roughly four interceptor launches per year. The moratorium undertaken during the ASAT negotiations produced another hiatus from May, 1978 to April, 1980. Substantial advances in weapons technology have occurred since the mid-1960s when the Soviet ASAT was designed, and an interceptor based on the older hardware would have inherently limited capabilities, reliability, and growth potential. Public accounts of the Soviet tests periodically given by the Defense Department, for instance, indicate that the interceptor has executed the steps necessary for target destruction in only about 50 percent of the tests. (Classified intelligence data on the Soviet program, of course, is much more precise and specific.)

This co-orbital interceptor assembled from the cumbersome technology of the 1960s requires a large launch booster comparable to the bigger Soviet ICBMs, and even with that it could only reach satellites in lower orbits.[6]

---

5. *Protivo-Kozmicheskaya Oborona*: literally, "anti-cosmic defense."
6. TRW, the American aerospace firm, has published data estimating the weight of the Soviet ASAT interceptor at about 4,500 pounds, identifying the booster as a missile adapted from the

Intercepting targets at geosynchronous orbits (i.e., "stationary" satellites at altitudes of 22,300 nm) would require a booster comparable to the U.S. Saturn-B rocket that launched the 85 ton Skylab. An extensive ASAT system based on such boosters would not only be extremely costly, it also would not be a fast-reaction system, since launch preparations for such boosters can require weeks or months. The Soviet interceptor itself has limited fuel for maneuvering, and thus is largely restricted to attacking when the target is in an orbital pass that would carry it almost directly over (i.e., in-plane with) the ASAT launch site—something that happens only once every twelve hours for any particular satellite in lower orbits.

Nonetheless, against satellites lacking defensive countermeasures, the demonstrated Soviet ASAT system could be, as Defense Secretary Brown has remarked, "somewhat troublesome." The lower orbits reachable with the Soviet ASAT are the ones used by the United States for many of its photo-reconnaissance, electronic intelligence, meteorological, and navigation satellite networks. With limited Soviet ASAT maneuverability and reliability, it could take days to weeks for the Soviets to eliminate entire U.S. satellite networks; but surprise attacks on a handful of U.S. satellites would be within the capabilities of the current Soviet system.

These Soviet and American programs by no means exhaust the range of possible ASAT schemes. The missions of some satellites can be impeded, even without sending interceptors against them, by using various methods of interference such as electronic jamming. Many satellites, as part of their mission (e.g., communications or navigational assistance), must pick up very weak radio signals, amplify them, and relay them on to other stations. In addition, satellites may require periodic "housekeeping" instructions radioed from earth so that they remain in appropriate orbit and orientation. Under some circumstances, an adversary may be able to use powerful transmitters, such as early warning radars or large space-communication antennae, to jam or even burn out the sensitive receivers on satellites and thus block their use. Similarly, the Soviets now have satellites capable of scanning the oceans with radar and detecting the echoes reflected back from ships on the surface. (The Soviets' Cosmos 954, which scattered radioactive debris over northern Canada when it fell from orbit in September 1977, was a satellite of this

---

Soviet SS-9 ICBM, and listing the launch dates and orbit configurations for Soviet targets and ASAT interceptors. The highest altitude listed for the interceptor in these tests was about 1,250 nm. See *TRW Space Log 1977*. The bulk of American non-geosynchronous satellites orbit the earth at altitudes of 100–20,000 nm.

type.) Such satellites are vulnerable not only to active jamming of the radar receiver, but also to a variety of passive countermeasures, such as decoy ships or "corner reflectors" that could confuse the radar by making small vessels appear as large ships.

The susceptibility of current satellites to such interference is difficult to estimate, because success with such techniques is highly dependent upon whether the attacker has good information about the satellite's electronics, whether he has jamming transmitters geographically distributed so they can overwhelm satellites at appropriate times, etc. These factors will vary from case to case, depending upon where, when, and in what form conflict occurs. But broadly speaking, these techniques are likely to be more disruptive to the tactical than to the strategic missions of satellites, and they are likely to be more successful against high altitude and geosynchronous satellites, rather than low orbit satellites.[7] An exception would be low orbit radar reconnaissance satellites, which appear to be particularly vulnerable to "spoofing." Interference must, therefore, be considered as part of the ASAT problem.

All this is rather prosaic ASAT weaponry. There is yet another whole class of potential ASAT weapons: directed-energy or "beam" weapons, such as lasers or charged-particle beams. By blinding, overheating, or even destroying fragile satellite components, such systems could work well as ASAT weapons. Among many specialists there is doubt that practical particle-beam weapons can even be built; fewer doubts exist about the feasibility of high-power laser weapons.

Ground-based laser weapons would have limited effectiveness against most satellites, even with power outputs in the megawatt range. Both cloud cover and the atmosphere rob laser beams of substantial power. The tendency of a laser beam to spread out over distance also complicates the task of bringing destructive energy to bear on distant satellites. Consequently, the threat from such weapons would be posed primarily to low orbit satellites. Airborne lasers would get above much of the atmosphere, but there are limits to the power output and lethal range of a laser that must be fitted into an airplane. A multi-megawatt orbiting laser weapon, on the other hand, could

---

7. The technical reason for this is that jamming requires line-of-sight, or even main-lobe access to the satellite's antenna as well as in-band power delivery greater than that of the satellite's own users. These conditions are easier to meet in tactical situations, where the satellite's users are probably nearby and operating with low-power transmitters, or where the high orbit of the satellite exposes it to line-of-sight access by powerful jamming transmitters in a wide geographical area.

operate above the power-robbing effects of the atmosphere and would be capable of damaging targets hundreds of miles away in outer space. But there are daunting technological challenges (and uncertain cost) to be faced in generating and aiming the explosive force of a multi-megawatt space laser, and even Defense Department enthusiasts of such weapons concede that they would not be available to the United States before the mid-1990s. Nonetheless, the destructive potential and probable cost of such futuristic weapons are sobering enough to suggest what unbridled arms competition in outer space might entail.

The seductive attraction of ASAT weapons is that in the absence of arms control restraints, it appears that technology will favor the offense over the defense. Plating satellites with armor or other protective coatings might work as a defense against unsophisticated conventional warheads or ground-based lasers, but not against the more advanced possibilities. (An MHV interceptor, for instance, colliding at speeds over 17,000 mph could defeat the armor of a battle tank.) Giving satellites the capacity to maneuver out of harm's way when attacked, or the capacity to destroy oncoming attackers with their own defensive lasers are suggested defenses. But a satellite defense system would first have to detect oncoming ASAT weapons, using active radars or optical scanners, and thus it would be susceptible to a crafty attacker who could jam or confuse the sensors and exhaust maneuvering engines or defensive lasers. One could envision satellites of the future burdened with thousands of pounds of defensive measures, just to protect a few hundred pounds of vital equipment. An alternative scheme advocated by some in the Defense Department would involve "convoying" satellites under the protection of huge defensive laser satellites. But satellites with different missions could not readily be clustered together into "convoys" without severely compromising their missions. And in any case, the protecting satellite would itself be subject to the problems of jamming and exhaustion just mentioned.

The vitality of satellite defenses could be restored if a cap were placed on offensive ASAT weapons, and this is what ASAT arms control would do. Consider, for instance, that a promising defensive technique for satellites would be simply to multiply the total number of satellites, so that the attacker's prospects of destroying them all in time to have a decisive impact upon a conflict would be diminished. The U.S. Space Shuttle will make satellite systems much cheaper, by reducing launching costs and by permitting retrieval or repair of satellites, thus reducing the need for overly durable and redundant equipment on them. By duplicating and diversifying missions

among a greater number of cheaper satellites (and storing some duplicates in orbit in an apparently inert condition to disguise their missions or presence), the defense could present a formidable challenge to any would-be attacker. The effectiveness of this approach declines, however, if the attacker has plenty of cheap, reliable ASAT interceptors available. And this underscores the importance of exploring ASAT arms control measures promptly.

As yet, neither the United States nor the Soviet Union has tested or deployed such an efficient ASAT device. Nor is there any immediate prospect of a cheap interceptor capable of reaching the large number of high-altitude and geosynchronous satellites. Even the U.S. MHV device would require a Minuteman-class booster to carry it up to geosynchronous altitudes. Yet undoubtedly, if ASAT competition continues without restraint, such devices will be developed and deployed. It is in this sense that the United States faces a ripe but perishable opportunity to avert greater threats to its satellite systems.

The Path to Arms Control for ASATs

Despite the attractiveness of an arms control approach to ASAT threats, it was not given broad consideration within the U.S. government until recently. Instead, policy tended to vacillate between indifference to the threat and strictly offensive responses to it, that is, acquiring our own ASAT capability. The Soviet ASAT program is over a decade old, and there were several interagency study groups assembled within the U.S. government during those years to examine U.S. policy on ASAT systems. Repeatedly the judgment had been made that neither the Soviet ASAT capability nor the increased Soviet military use of space satellites warranted U.S. investment in an extensive ASAT system. In a period of tight military budgets, the emphasis had been upon using limited funds to improve U.S. exploitation of space, rather than on trying to threaten Soviet satellites.

The turning point came literally in the final days of the Ford Administration, when a National Security Council decision memorandum instructed the Defense Department to begin a new ASAT program. The precipitating event was the resumption of Soviet ASAT testing in 1976. Arguments were already being made within the State Department, urging the administration to seek an ASAT arms control agreement. Instead, Secretary of State Kissinger argued that the U.S. should redress any asymmetry in ASAT capabilities between the sides before any arms control restraints were considered. The

directive by the Ford Administration to go ahead with the MHV system did call for a study of arms control options, but it did not include any concrete proposal for inviting the Soviets to ASAT talks. Kissinger may have felt it was premature to make such a proposal; or indeed, he may not have favored negotiations at all.

The case made by the Defense Department for acquiring an ASAT system, however, had a number of defects. The initial argument was that the United States ought to match the Soviet ASAT capacity as a means of deterring attacks on U.S. satellites. Yet if the U.S. is indeed becoming more dependent upon satellites for its military effectiveness, then it is well to bear in mind that destroying Soviet satellites in a rage of retaliation will not restore our own satellite capabilities.

Deterrence has other shortcomings as well. It is not obvious that the mere threat of U.S. retaliation would deter the Soviets from attacking U.S. satellites, because Soviet dependence upon satellites is lower than American dependence. The Soviets have fewer military forces deployed beyond their homeland and thus can rely upon interior (ground-based) lines of communication. Their strategic forces have less need for worldwide communications or navigation aids, since their strategic bomber fleet is so small and their longer-range SLBM submarines can operate near home shores. The role of the Soviet Navy is sea interdiction rather than the more demanding task of sea control, and thus it may be less dependent upon global communications for coordination and control. For conflicts near the Soviet borders, ground-based surveillance and reconnaissance systems can fill gaps created by the loss of satellites. And lastly, Soviet military planning is aimed at short, intense warfare begun with surprise and massive shock. Here the emphasis would be upon commands and data distributed before the conflict begins, when the United States would be inhibited from preemptive attacks on Soviet satellites. (Passive concealment techniques for confusing Soviet radar reconnaissance or intelligence satellites, on the other hand, would not involve such inhibitions.)

In evaluating the efficacy of deterrence, the United States must make some judgments about where conflicts are most likely to occur. If, as seems likely, the vital conflicts would be on the Soviet periphery (in Europe, the Persian Gulf, the Middle East), then the Soviets might well be able to get along without their satellites—which means that a U.S. retaliatory threat would have doubtful deterrence value. The weakness of the deterrence argument was recently conceded by Seymour Zeiberg, deputy undersecretary of Defense R&D for space systems, who oversees the U.S. ASAT project:

The idea of tit-for-tat with satellites to my mind does not make sense because of the great asymmetry in the nature of [U.S. and Soviet] satellites, the deployment of satellites, etc. . . . For example, the Soviets have a very redundant communications system to thei forces. They have two of everything. So taking out a communications satellite is not going to extract much of a price from them. If they took out one of our communications satellites, it would be quite different.[8]

What the Defense Department now argues instead is that the United States needs an ASAT capability in order to initiate attacks on a relatively small number of Soviet satellites that pose a danger to U.S. forces. Of particular concern are the Soviet radar and electronic surveillance satellites that can scan the oceans for U.S. naval forces and provide targeting information for, say, long-range cruise missiles. Even if shooting these satellites down is the only way to cope with them (and that has not been demonstrated), the problem with this argument is that, as the price for having its own ASAT, the United States will also be exposing all of its own satellites to comparable Soviet ASAT threats. If deterrence cannot protect U.S. space systems in a world of ASATs, what then is the alternative?

The answer of the Ford Administration was a rapid surge in spending on "space defense systems," increased in the Defense Department budget from $61 million in FY 1977 to $126 million proposed for FY 1978, and $265 million projected for FY 1979. But these figures were quite misleading. A substantial chunk of the funding was for the MHV program; actual funding fell short of projections ($73.0 million in FY 1979, not $265 million); and only a small portion of the funding was actually devoted to the category of "satellite survivability" (only $19 million of the $73 million in FY 1979).[9] Even within this latter category were contained programs for devices, such as impact sensors, that would detect when a satellite had been attacked but would not in themselves make the satellite survivable. There were, and still are futuristic schemes aplenty being studied (laser and charged-particle satellites, "convoying," etc.), but nothing available for the near term that could even cope with our own MHV interceptor. So by insisting upon an ASAT solution to one problem, the military services are exposing themselves to a vast range

8. U.S. Congress, Senate Subcommittee of the Committee on Armed Services, Hearings, Authorization for Appropriations FY 1980, 96th Congress, First session, Part 6, p. 3027.
9. For FY 1980, funding of $80.5 million was requested for "space defense systems," all of it for various ASAT programs. An additional $30 million was requested for "satellite survivability," of which $11.6 million was for actual survivability technology. Congress has shown reluctance to approve even these modest funding levels.

of problems for the operation of all U.S. military forces, given their dependence upon satellite systems.

Problems of this sort convinced President Carter to add ASAT restraints to the list of arms control topics that he raised with the Soviet Union in the early days of his administration. The matter was broached with Moscow in March, 1977, and the sides subsequently agreed that a joint "working group" on the issue should be established. A year of delay then followed as the United States prepared for substantive negotiations. During this time, policy flesh was added to the spare skeleton of President Carter's initial proposal by a U.S. inter-agency study group, staffed by representatives from the NSC, the Defense Department, State, the Joint Chiefs, the Arms Control and Disarmament Agency, the CIA, and NASA. By this path, the two sides reached the negotiating table at Helsinki in June, 1978.

Approaches to the Control of ASAT Weapons

Public statements by the Carter Administration regarding its specific goals or proposals at the ASAT negotiations have been quite spare: the United States seeks comprehensive and verifiable limits on ASAT capabilities, and in the event such limits cannot be negotiated, it will acquire an ASAT capability of its own. Nonetheless, we can consider what an ASAT agreement might contain, if it is to serve American security interests.

Currently, the U.S. and Soviet Union are party to a series of international treaties that offer some margin of protection to satellites, although the sides have not directly addressed ASAT weapons in previous arms control talks. None of these existing accords, however, would serve as well in stemming an ASAT arms competition as a new treaty specifically focused on these weapons. For instance, provisions of the Limited Test Ban Treaty (1963) and the Outer Space Treaty (1967) would ban the sides from placing nuclear-armed ASAT weapons into orbit and would prohibit them from detonating nuclear warheads in outer space. But nuclear-armed interceptors are only one (and perhaps the least likely) type of potential ASAT weapon. Hence, the restrictions in these two accords certainly do not exhaust the range of constraints needed.[10]

---

10. Unofficially, the Soviets have claimed broad scope for the Outer Space Treaty in banning ASAT systems. A TASS broadcast on April 4, 1977, stated that the United States had a "secret program to create means of destroying 'enemy satellites'" (evidently a reference to the MHV

Acts of interference with satellites are also in partial measure covered by several agreements. Article II of the Accidents Measures Agreement (1971) addresses interference with early warning systems, of which satellites would be one part, if such interference "could create a risk of outbreak of nuclear war." But this accord only obligates the sides to "notify each other immediately" when such interference is detected. By implication, however, if such acts of interference could indeed pose a risk of war, then the two sides would be obliged to refrain from such interference with early warning systems under the Agreement on the Prevention of Nuclear War (1974). There are also a number of general regulations governing radio-frequency interference contained in the Convention of the International Telecommunications Union, whose intention is to provide for the orderly use of the airwaves. Further constraints on interference are contained in the agreements of SALT I and II, where interference with satellites serving as part of "national technical means of verification" is prohibited.

The deficiency of these accords is that they govern only some attacks with ASAT weapons and only certain forms of interference. They do not address the whole range of threats nor other provocative aspects of an arms competition such as testing or deployment of ASAT systems. The goal of a new ASAT agreement would be to supplement, not to supplant the obligations of these existing treaties.

There are two basic approaches that could be taken in drafting an ASAT agreement: define in detail what an ASAT weapon consists of and ban all such weapons; or, ban the testing, deployment, or use of any weapon in a manner appropriate for attacking satellites. The contrast here is between banning things and banning actions.

Banning itemized things has numerous difficulties. Overly explicit itemizations of things which are prohibited can provide a road map for circumventing the intent of a treaty while remaining within its letter. However fertile the imaginations of treaty draftsmen in anticipating possible ASAT weapon designs, there will always be new technologies or techniques that

---

project). TASS asserted that even an R&D program along these lines was "in direct violation" of the Outer Space Treaty. It is not clear what to make of this assertion, since by the same principle, the ongoing Soviet ASAT interceptor program would also have been in violation of the Treaty. In an equally broad interpretation, the TASS broadcast held that the U.S. Space Shuttle program was also banned under the same treaty. Officially, the Soviets have asserted that the Outer Space Treaty does not prohibit them from taking whatever action they choose against satellites engaged in military or other hostile acts against the Soviet Union.

will be overlooked. A treaty highly explicit in its definitions entails the risk of implying that any unspecified item is thus not subject to constraint. Yet another problem is that many of the capabilities that would be incorporated in an ASAT weapon (e.g., homing and maneuvering capabilities) may also be present in other space vehicles. Any attempt to ban all hardware with such capabilities could cripple non-ASAT space programs. Similarly, attempts to define and prohibit all equipment technically capable of electronic interference with satellites could cripple vital early warning radars and space communications systems (and could tell the other side precisely how vulnerable our satellites were to which kinds of electronic interference).

The inadvisability or simple impossibility of minutely defining all the restricted features of all conceivable ASAT weapons thus draws our attention to the second approach: banning ASAT activities, regardless of the equipment used. A model for this approach is the ABM Treaty, which broadly specifies and then restricts systems according to their use, i.e., any "system to counter strategic ballistic missiles or their elements in flight trajectory" (Article II.1). An ASAT agreement following this approach would contain two major obligations: 1) each side would agree not to use, not to deploy, and not to test any weapon or system for damaging or destroying satellites; and 2) each side would agree not to interfere with the functioning of the other's satellites. Testing in this context would refer to tests against targets in space. Other R&D on ASAT technologies, if confined to the laboratory, would not be subject to constraint. A ban on *all* R&D would be exceptionally difficult to verify, and as long as tests of ASAT prototypes against targets in simulated attacks are banned, neither side need fear that the other will acquire a high-confidence, agile ASAT system on the basis of lab work alone.

Treaty provisions along these lines would provide a number of benefits. The benefits from a prohibition on interference would be more modest but still worthwhile. It would be impractical to ban all equipment technically capable of interfering with satellites, so a ban only on acts of interference would not in itself eliminate all dangers. However, it would enhance the effectiveness of satellites in the normal course of things (something worth having especially in the case of intelligence satellites), it would diminish the chance of provocative acts involving all satellites, and it would prohibit the Soviets from practicing interference techniques on our satellites.

Major benefits would come from the ban on testing, deployment, and use of weapons for damaging or destroying satellites, for this would stunt the growth of offensive ASAT technologies while giving free rein to defensive

measures for protecting satellites. These provisions are crafted to have minimal adverse impact upon other, non-ASAT space programs. And some may regard this as a weakness rather than a virtue. A critic with imagination, for instance, might argue that the maneuverable *Progress* resupply vehicles used by the Soviets in their SALYUT manned space laboratory program could also be used to ram U.S. satellites, and thus must be banned if an ASAT agreement is to have any value. But this casts the alternatives too starkly. While some residual hazards from other space vehicles are conceivable, it is hard to see them as a compelling reason for abandoning ourselves entirely to unrestrained ASAT competition. Our ability to protect our satellites through some modest defensive measures will obviously be greater if the residual ASAT threat comes only from hardware designed for other purposes, banned from ASAT testing, and pressed into service only in an *ad hoc* way during conflict. An ASAT agreement should not induce us to be complacent about the survivability of our satellites. But it does offer a promising, indeed the only prospect of reducing the survivability problem to manageable proportions.

There are additional provisions necessary in an ASAT accord. The Soviet Union has already tested an ASAT interceptor, and this asymmetry must be addressed. There are strong voices in the U.S. government, particularly in the military services, which urge delay in any negotiations until the United States has tested a comparable ASAT capability. But advocates of this policy have not proposed a U.S. ASAT system "comparable" to the Soviets', that is, based upon 1960s technology. The U.S. MHV would be orders of magnitude more advanced. Moreover, a general promise from the United States to negotiate restraints "someday" when we catch up to Soviet capabilities does not offer the Soviets much incentive to restrain their own ASAT program. In the interim, they might well conduct ASAT tests with an improved interceptor or against higher altitude targets, thus multiplying the defensive problems for U.S. satellites.

To get around these difficulties, some have argued for a two-tier ban, prohibiting high altitude tests altogether while temporarily permitting ASAT tests below some threshold (e.g., below 2,000 nm). This would supposedly give the United States a chance to match the current Soviet capability while preventing the Soviets from extending their threat to higher U.S. satellites. But this proposal has technical flaws. ASAT weapons for attacking higher altitude satellites do have more exacting performance requirements, but systems meeting these rigorous standards could be constructed and amply tested

against targets below the threshold altitude. The practical consequence of a two-tier ban, therefore, would be the same as having no test ban at all.

The preferable course for dealing with the current asymmetry in ASAT capability is to require the Soviets to dismantle their present ASAT system. Getting them to give up a military capability in which they enjoy a current lead will not be easy. Yet the Soviets must certainly anticipate that the United States will engage them in a costly ASAT competition if there is no ASAT ban. Hence, the issue for the Soviets is the same as for the Americans—is it profitable to push arms competition in an arena where neither side can hope to sustain an operational advantage? Soviet willingness to accept limitations and even substantial reductions in strategic arms at SALT (including abstaining from extensive ABM defenses altogether) suggests that the Soviets are open to such arguments.

Compliance with these ASAT restrictions would be verified by the extensive intelligence and space surveillance facilities already available and being acquired by the United States. The Space Detection and Tracking System (SPADATS) currently enables the U.S. to detect, classify, and maintain an updated computer catalog of the identity and orbit of all space objects—currently in excess of 4,000 satellites, pieces of debris, etc. The completion of the GEODSS high-altitude tracking system now under construction will enable SPADATS to monitor objects as small as one foot in diameter in orbits up to 23,000 nm. The array of electronic and optical sensors deployed around and over the Soviet Union permits comparable tracking and classification of Soviet missile and space launches. Together these facilities would verify the ban on ASAT testing, deployment, and use by monitoring for telltale features of an ASAT program. These would vary from weapon to weapon, but any ASAT system would expose itself at many points to detection: e.g., direct-ascent, co-orbital, and space-based laser interceptors would require launch preparations, launching, and maneuvering to altitudes and orbital planes appropriate for ASAT attacks; ground- or space-based lasers or charged particle weapons would involve the rapid discharge of high levels of energy and possible waste products of power generation; in all cases, the damage, intense heating, destruction, or displacement from its orbit of a target could be detectable.

We should consider that the Soviets might press along with a variety of untested ASAT weapons as far as laboratory work could carry them, looking ahead to using untested systems in a conflict; or alternatively that they might conduct covert tests in the guise of other space programs. But neither of

these schemes would be very promising. The more technically sophisticated a weapon is, the more military planners will insist upon full-scale testing. Indeed, if the kill mechanism of the weapon requires high accuracy (as all non-nuclear and laser ASATs would), full-scale testing could be indispensable to confirm whether the design works at all. Given past surprises and catastrophes in test programs of advanced weapons, few military commanders would be satisfied with an ASAT device tested only in the lab or covertly, in pieces, under the cover of other space programs. Moreover, any covert program would have to reckon with the close scrutiny to which Soviet space programs are subjected by U.S. intelligence agencies, with their long experience at sifting the unusual from the familiar. To have confidence in successfully and repeatedly evading such scrutiny, the Soviets would have to know in minute detail what U.S. intelligence looks for and has already learned.

Verifying the treaty provision on interference would require additional monitoring facilities beyond those used to monitor testing. But again these are facilities that the U.S. is acquiring and will continue to improve upon. Precisely because attacks on, or interference with our satellites might be a prelude to other hostile acts, the United States has an interest in knowing when its satellites are being tampered with and by whom, even in the absence of an ASAT agreement. Detectors mounted on satellites for monitoring the nature and source of interference are therefore needed in any case, and they can also serve the purpose of verifying the prohibitions in an ASAT treaty. In fact, an ASAT accord would considerably enhance the usefulness of such detectors in providing warning. Unless deliberate interference with satellites is banned, U.S. satellites would be vulnerable to repeated "spoofing," until a string of such false alarms had dulled our alertness to an actual attack. Under a general ban on interference, any episode of this sort would be a red flag warning us to pay attention.[11]

The most troublesome verification problem will be posed by the current Soviet ASAT system. The Soviet system uses a number of components and facilities that are shared with other Soviet space missions and weapon systems. The verification issue here is not one of knowing whether the Soviet

---

11. All communications and electronic intelligence satellites have some inherent capability for detecting and locating radio-frequency interference. President Carter, in a Presidential Decision Memorandum of May, 1978, has ordered that monitoring and survivability equipment be incorporated in all future U.S. satellite systems. The Defense Department has already begun to implement the President's directive.

ASAT system proper has been dismantled or is no longer being tested. The question is whether it could be rapidly re-assembled on a jury-rigged basis, using these shared facilities. The United States would have a hedge against this problem, because it would be free to implement survivability measures to make its satellites progressively less vulnerable to the older technology embodied in the Soviet ASAT interceptor. And a prolonged period of not testing the system would also erode Soviet confidence in any such "break-out" schemes. Nonetheless, the thoroughness of Soviet dismantling efforts will be an important issue in public evaluation of any potential ASAT treaty, and Soviet willingness to go the extra mile on this matter will undoubtedly be taken as a hallmark of Soviet earnestness in ASAT arms control.

The Soviets have thus far shown important signs of taking these ASAT issues seriously. As head of their ASAT delegation, the Soviets appointed Oleg N. Khlestov, an authority on space law with service as the Chief of the Treaty and Legal Department in the Ministry of Foreign Affairs. At the first round of talks in Helsinki, the Soviets insisted upon labeling the sessions as no more than "preliminary consultations," reflecting the uncertainties of dealing with a novel topic. But by the second round in Bern (January 23–February 16, 1979), they were willing to make the symbolic transition to "negotiations seeking concrete results." Round three in Vienna (April 23–June 17, 1979) was equally frank and businesslike in the exchange of viewpoints and tentative proposals. The Soviet willingness to suspend their ASAT testing program while the talks were in progress may also be taken as a sign of seriousness. Certainly the United States loses nothing by continuing to explore Soviet interest in ASAT constraints along the lines sketched here. The Defense Department's R&D program on ASAT systems is vigorous enough to protect our other options, should ASAT talks come to naught.

Conclusion

Arms control proposals have not enjoyed a congenial political atmosphere in the United States, even before the Soviet invasion of Afghanistan. As a consequence, advocates of arms control have often been more zealous in asserting the virtues of their proposals than prudence would counsel. That temptation should be resisted in the case of an ASAT agreement. The limitations on ASAT competition outlined here are no panacea; they offer to contrain the threats to U.S. satellites to manageable proportions, not to eliminate each and every threat now and forever. As such, these measures

will be unsatisfying to those who insist that, to be acceptable, arms control accords must be foolproof and comprehensive in averting all threats.

The virtues of an ASAT agreement are best measured by considering its most likely alternative—an unbridled competition in space weaponry. Enthusiasts of the U.S. MHV project may speak with delight, as one White House aide did, of "sweeping the skies clean in twenty-four hours." Yet if the MHV is going to be as nimble as its project managers claim, then clearly the United States ought to be planning now for a transition to lesser dependence upon satellites. For in the absence of agreed restraints, there is nothing to prevent the Soviets from acquiring an ASAT capability comparable to the MHV and doing their own sweeping. Yet instead, the Defense Department has been doing just the opposite, drifting toward greater reliance upon space systems. Advocates of the MHV talk as if this growing dependency in the emerging era of space warfare is a problem manageable through an old solution—the doctrine of deterrence—yet even the Defense Department undersecretary overseeing the MHV project sees no promise in that doctrine.

Constraining threats to U.S. interests through the exercise of enlightened mutual restraint on the acquisition of weapons is a practice that does not come easily to American policymakers. It requires both vision and discipline to break from the habit of believing that any weapon which can be built ought to be built; that any advantage within grasp, however fleeting and costly in the long term, ought to be seized. We will not have acted wisely if, from untempered force of habit, we reject this opportunity to explore limits on arms competition in outer space.

V. RESOURCE ALLOCATION AMONG COMPETING NATIONAL PRIORITIES

205 Special Message to the Congress on Urgent National Needs. *May 25, 1961*

[Delivered in person before a joint session]

Mr. Speaker, Mr. Vice President, my co-partners in Government, gentlemen—and ladies:

The Constitution imposes upon me the obligation to "from time to time give to the Congress information of the State of the Union." While this has traditionally been interpreted as an annual affair, this tradition has been broken in extraordinary times.

These are extraordinary times. And we face an extraordinary challenge. Our strength as well as our convictions have imposed upon this nation the role of leader in freedom's cause.

No role in history could be more difficult or more important. We stand for freedom.

Reproduced from Public Papers of the Presidents of the United States: John F. Kennedy, 1961. Washington, G.P.O., 1962. p. 396-406.

That is our conviction for ourselves—that is our only commitment to others. No friend, no neutral and no adversary should think otherwise. We are not against any man—or any nation—or any system—except as it is hostile to freedom. Nor am I here to present a new military doctrine, bearing any one name or aimed at any one area. I am here to promote the freedom doctrine.

I.

The great battleground for the defense and expansion of freedom today is the whole southern half of the globe—Asia, Latin America, Africa and the Middle East—the lands of the rising peoples. Their revolution is the greatest in human history. They seek an end to injustice, tyranny, and exploitation. More than an end, they seek a beginning.

And theirs is a revolution which we would support regardless of the Cold War, and regardless of which political or economic route they should choose to freedom.

For the adversaries of freedom did not create the revolution; nor did they create the conditions which compel it. But they are seeking to ride the crest of its wave—to capture it for themselves.

Yet their aggression is more often concealed than open. They have fired no missiles; and their troops are seldom seen. They send arms, agitators, aid, technicians and propaganda to every troubled area. But where fighting is required, it is usually done by others—by guerrillas striking at night, by assassins striking alone—assassins who have taken the lives of four thousand civil officers in the last twelve months in Vietnam alone—by subversives and saboteurs and insurrectionists, who in some cases control whole areas inside of independent nations.[1]

With these formidable weapons, the adversaries of freedom plan to consolidate their territory—to exploit, to control, and finally to destroy the hopes of the world's newest nations; and they have ambition to do it before the end of this decade. It is a contest of will and purpose as well as force and violence—a battle for minds and souls as well as lives and territory. And in that contest, we cannot stand aside.

We stand, as we have always stood from our earliest beginnings, for the independence and equality of all nations. This nation was born of revolution and raised in freedom. And we do not intend to leave an open road for despotism.

There is no single simple policy which meets this challenge. Experience has taught us that no one nation has the power or the wisdom to solve all the problems of the world or manage its revolutionary tides—that extending our commitments does not always increase our security—that any initiative carries with it the risk of a temporary defeat—that nuclear weapons cannot prevent subversion—that no free people can be kept free without will and energy of their own—

[1] At this point the following paragraph, which appears in the text as signed and transmitted to the Senate and House of Representatives, was omitted in the reading of the message:

They possess a powerful intercontinental striking force, large forces for conventional war, a well-trained underground in nearly every country, the power to conscript talent and manpower for any purpose, the capacity for quick decisions, a closed society without dissent or free information, and long experience in the techniques of violence and subversion. They make the most of their scientific successes, their economic progress and their pose as a foe of colonialism and friend of popular revolution. They prey on unstable or unpopular governments, unsealed, or unknown boundaries, unfilled hopes, convulsive change, massive poverty, illiteracy, unrest and frustration.

and that no two nations or situations are exactly alike.

Yet there is much we can do—and must do. The proposals I bring before you are numerous and varied. They arise from the host of special opportunities and dangers which have become increasingly clear in recent months. Taken together, I believe that they can mark another step forward in our effort as a people. I am here to ask the help of this Congress and the nation in approving these necessary measures.

II. ECONOMIC AND SOCIAL PROGRESS AT HOME

The first and basic task confronting this nation this year was to turn recession into recovery. An affirmative anti-recession program, initiated with your cooperation, supported the natural forces in the private sector; and our economy is now enjoying renewed confidence and energy. The recession has been halted. Recovery is under way.

But the task of abating unemployment and achieving a full use of our resources does remain a serious challenge for us all. Large-scale unemployment during a recession is bad enough, but large-scale unemployment during a period of prosperity would be intolerable.

I am therefore transmitting to the Congress a new Manpower Development and Training program, to train or retrain several hundred thousand workers, particularly in those areas where we have seen chronic unemployment as a result of technological factors in new occupational skills over a four-year period, in order to replace those skills made obsolete by automation and industrial change with the new skills which the new processes demand.

It should be a satisfaction to us all that we have made great strides in restoring world confidence in the dollar, halting the outflow of gold and improving our balance of payments. During the last two months, our gold stocks actually increased by seventeen million dollars, compared to a loss of 635 million dollars during the last two months of 1960. We must maintain this progress—and this will require the cooperation and restraint of everyone. As recovery progresses, there will be temptations to seek unjustified price and wage increases. These we cannot afford. They will only handicap our efforts to compete abroad and to achieve full recovery here at home. Labor and management must—and I am confident that they will—pursue responsible wage and price policies in these critical times. I look to the President's Advisory Committee on Labor-Management Policy to give a strong lead in this direction.

Moreover, if the budget deficit now increased by the needs of our security is to be held within manageable proportions, it will be necessary to hold tightly to prudent fiscal standards; and I request the cooperation of the Congress in this regard—to refrain from adding funds or programs, desirable as they may be, to the Budget—to end the postal deficit, as my predecessor also recommended, through increased rates—a deficit incidentally, this year, which exceeds the fiscal 1962 cost of all the space and defense measures that I am submitting today—to provide full pay-as-you-go highway financing—and to close those tax loopholes earlier specified. Our security and progress cannot be cheaply purchased; and their price must be found in what we all forego as well as what we all must pay.

III. ECONOMIC AND SOCIAL PROGRESS ABROAD

I stress the strength of our economy because it is essential to the strength of our

nation. And what is true in our case is true in the case of other countries. Their strength in the struggle for freedom depends on the strength of their economic and their social progress.

We would be badly mistaken to consider their problems in military terms alone. For no amount of arms and armies can help stabilize those governments which are unable or unwilling to achieve social and economic reform and development. Military pacts cannot help nations whose social injustice and economic chaos invite insurgency and penetration and subversion. The most skillful counter-guerrilla efforts cannot succeed where the local population is too caught up in its own misery to be concerned about the advance of communism.

But for those who share this view, we stand ready now, as we have in the past, to provide generously of our skills, and our capital, and our food to assist the peoples of the less-developed nations to reach their goals in freedom—to help them before they are engulfed in crisis.

This is also our great opportunity in 1961. If we grasp it, then subversion to prevent its success is exposed as an unjustifiable attempt to keep these nations from either being free or equal. But if we do not pursue it, and if they do not pursue it, the bankruptcy of unstable governments, one by one, and of unfilled hopes will surely lead to a series of totalitarian receiverships.

Earlier in the year, I outlined to the Congress a new program for aiding emerging nations; and it is my intention to transmit shortly draft legislation to implement this program, to establish a new Act for International Development, and to add to the figures previously requested, in view of the swift pace of critical events, an additional 250 million dollars for a Presidential Contingency Fund, to be used only upon a Presidential determination in each case, with regular and complete reports to the Congress in each case, when there is a sudden and extraordinary drain upon our regular funds which we cannot foresee—as illustrated by recent events in Southeast Asia—and it makes necessary the use of this emergency reserve. The total amount requested—now raised to 2.65 billion dollars—is both minimal and crucial. I do not see how anyone who is concerned—as we all are—about the growing threats to freedom around the globe—and who is asking what more we can do as a people—can weaken or oppose the single most important program available for building the frontiers of freedom.

IV.

All that I have said makes it clear that we are engaged in a world-wide struggle in which we bear a heavy burden to preserve and promote the ideals that we share with all mankind, or have alien ideals forced upon them. That struggle has highlighted the role of our Information Agency. It is essential that the funds previously requested for this effort be not only approved in full, but increased by 2 million, 400 thousand dollars, to a total of 121 million dollars.

This new request is for additional radio and television to Latin America and Southeast Asia. These tools are particularly effective and essential in the cities and villages of those great continents as a means of reaching millions of uncertain peoples to tell them of our interest in their fight for freedom. In Latin America, we are proposing to increase our Spanish and Portuguese broadcasts to a total of 154 hours a week, compared to 42 hours today, none of which is in Portuguese, the language of about one-third of the people of South America. The Soviets, Red Chinese and satellites already broadcast into

Latin America more than 134 hours a week in Spanish and Portuguese. Communist China alone does more public information broadcasting in our own hemisphere than we do. Moreover, powerful propaganda broadcasts from Havana now are heard throughout Latin America, encouraging new revolutions in several countries.

Similarly, in Laos, Vietnam, Cambodia, and Thailand, we must communicate our determination and support to those upon whom our hopes for resisting the communist tide in that continent ultimately depend. Our interest is in the truth.

V. OUR PARTNERSHIP FOR SELF-DEFENSE

But while we talk of sharing and building and the competition of ideas, others talk of arms and threaten war. So we have learned to keep our defenses strong—and to cooperate with others in a partnership of self-defense. The events of recent weeks have caused us to look anew at these efforts.

The center of freedom's defense is our network of world alliances, extending from NATO, recommended by a Democratic President and approved by a Republican Congress, to SEATO, recommended by a Republican President and approved by a Democratic Congress. These alliances were constructed in the 1940's and 1950's—it is our task and responsibility in the 1960's to strengthen them.

To meet the changing conditions of power—and power relationships have changed—we have endorsed an increased emphasis on NATO's conventional strength. At the same time we are affirming our conviction that the NATO nuclear deterrent must also be kept strong. I have made clear our intention to commit to the NATO command, for this purpose, the 5 Polaris submarines originally suggested by President Eisenhower, with the possibility, if needed, of more to come.

Second, a major part of our partnership for self-defense is the Military Assistance Program. The main burden of local defense against local attack, subversion, insurrection or guerrilla warfare must of necessity rest with local forces. Where these forces have the necessary will and capacity to cope with such threats, our intervention is rarely necessary or helpful. Where the will is present and only capacity is lacking, our Military Assistance Program can be of help.

But this program, like economic assistance, needs a new emphasis. It cannot be extended without regard to the social, political and military reforms essential to internal respect and stability. The equipment and training provided must be tailored to legitimate local needs and to our own foreign and military policies, not to our supply of military stocks or a local leader's desire for military display. And military assistance can, in addition to its military purposes, make a contribution to economic progress, as do our own Army Engineers.

In an earlier message, I requested 1.6 billion dollars for Military Assistance, stating that this would maintain existing force levels, but that I could not foresee how much more might be required. It is now clear that this is not enough. The present crisis in Southeast Asia, on which the Vice President has made a valuable report—the rising threat of communism in Latin America—the increased arms traffic in Africa—and all the new pressures on every nation found on the map by tracing your fingers along the borders of the Communist bloc in Asia and the Middle East—all make clear the dimension of our needs.

I therefore request the Congress to provide a total of 1.885 billion dollars for Military Assistance in the coming fiscal year—an

38-036 O - 84 - 91

amount less than that requested a year ago—but a minimum which must be assured if we are to help those nations make secure their independence. This must be prudently and wisely spent—and that will be our common endeavor. Military and economic assistance has been a heavy burden on our citizens for a long time, and I recognize the strong pressures against it; but this battle is far from over, it is reaching a crucial stage, and I believe we should participate in it. We cannot merely state our opposition to totalitarian advance without paying the price of helping those now under the greatest pressure.

VI. OUR OWN MILITARY AND INTELLIGENCE SHIELD

In line with these developments, I have directed a further reinforcement of our own capacity to deter or resist non-nuclear aggression. In the conventional field, with one exception, I find no present need for large new levies of men. What is needed is rather a change of position to give us still further increases in flexibility.

Therefore, I am directing the Secretary of Defense to undertake a reorganization and modernization of the Army's divisional structure, to increase its non-nuclear firepower, to improve its tactical mobility in any environment, to insure its flexibility to meet any direct or indirect threat, to facilitate its coordination with our major allies, and to provide more modern mechanized divisions in Europe and bring their equipment up to date, and new airborne brigades in both the Pacific and Europe.

And secondly, I am asking the Congress for an additional 100 million dollars to begin the procurement task necessary to re-equip this new Army structure with the most modern material. New helicopters, new armored personnel carriers, and new howitzers, for example, must be obtained now.

Third, I am directing the Secretary of Defense to expand rapidly and substantially, in cooperation with our Allies, the orientation of existing forces for the conduct of non-nuclear war, para-military operations and sub-limited or unconventional wars.

In addition, our special forces and unconventional warfare units will be increased and reoriented. Throughout the services new emphasis must be placed on the special skills and languages which are required to work with local populations.

Fourth, the Army is developing plans to make possible a much more rapid deployment of a major portion of its highly trained reserve forces. When these plans are completed and the reserve is strengthened, two combat-equipped divisions, plus their supporting forces, a total of 89,000 men, could be ready in an emergency for operations with but 3 weeks' notice—2 more divisions with but 5 weeks' notice—and six additional divisions and their supporting forces, making a total of 10 divisions, could be deployable with less than 8 weeks' notice. In short, these new plans will allow us to almost double the combat power of the Army in less than two months, compared to the nearly nine months heretofore required.

Fifth, to enhance the already formidable ability of the Marine Corps to respond to limited war emergencies, I am asking the Congress for 60 million dollars to increase the Marine Corps strength to 190,000 men. This will increase the initial impact and staying power of our three Marine divisions and three air wings, and provide a trained nucleus for further expansion, if necessary for self-defense.

Finally, to cite one other area of activities that are both legitimate and necessary as a means of self-defense in an age of hidden

perils, our whole intelligence effort must be reviewed, and its coordination with other elements of policy assured. The Congress and the American people are entitled to know that we will institute whatever new organization, policies, and control are necessary.

VII. CIVIL DEFENSE

One major element of the national security program which this nation has never squarely faced up to is civil defense. This problem arises not from present trends but from national inaction in which most of us have participated. In the past decade we have intermittently considered a variety of programs, but we have never adopted a consistent policy. Public considerations have been largely characterized by apathy, indifference and skepticism; while, at the same time, many of the civil defense plans have been so far-reaching and unrealistic that they have not gained essential support.

This Administration has been looking hard at exactly what civil defense can and cannot do. It cannot be obtained cheaply. It cannot give an assurance of blast protection that will be proof against surprise attack or guaranteed against obsolescence or destruction. And it cannot deter a nuclear attack.

We will deter an enemy from making a nuclear attack only if our retaliatory power is so strong and so invulnerable that he knows he would be destroyed by our response. If we have that strength, civil defense is not needed to deter an attack. If we should ever lack it, civil defense would not be an adequate substitute.

But this deterrent concept assumes rational calculations by rational men. And the history of this planet, and particularly the history of the 20th century, is sufficient to remind us of the possibilities of an irrational attack, a miscalculation, an accidental war, [or a war of escalation in which the stakes by each side gradually increase to the point of maximum danger] which cannot be either foreseen or deterred. It is on this basis that civil defense can be readily justifiable—as insurance for the civilian population in case of an enemy miscalculation. It is insurance we trust will never be needed—but insurance which we could never forgive ourselves for foregoing in the event of catastrophe.

Once the validity of this concept is recognized, there is no point in delaying the initiation of a nation-wide long-range program of identifying present fallout shelter capacity and providing shelter in new and existing structures. Such a program would protect millions of people against the hazards of radioactive fallout in the event of large-scale nuclear attack. Effective performance of the entire program not only requires new legislative authority and more funds, but also sound organizational arrangements.

Therefore, under the authority vested in me by Reorganization Plan No. 1 of 1958, I am assigning responsibility for this program to the top civilian authority already responsible for continental defense, the Secretary of Defense. It is important that this function remain civilian, in nature and leadership; and this feature will not be changed.

The Office of Civil and Defense Mobilization will be reconstituted as a small staff agency to assist in the coordination of these functions. To more accurately describe its role, its title should be changed to the Office of Emergency Planning.

As soon as those newly charged with these responsibilities have prepared new authorization and appropriation requests, such requests will be transmitted to the Congress for a much strengthened Federal-State civil

defense program. Such a program will provide Federal funds for identifying fallout shelter capacity in existing structures, and it will include, where appropriate, incorporation of shelter in Federal buildings, new requirements for shelter in buildings constructed with Federal assistance, and matching grants and other incentives for constructing shelter in State and local and private buildings.

Federal appropriations for civil defense in fiscal 1962 under this program will in all likelihood be more than triple the pending budget requests; and they will increase sharply in subsequent years. Financial participation will also be required from State and local governments and from private citizens. But no insurance is cost-free; and every American citizen and his community must decide for themselves whether this form of survival insurance justifies the expenditure of effort, time and money. For myself, I am convinced that it does.

VIII. DISARMAMENT

I cannot end this discussion of defense and armaments without emphasizing our strongest hope: the creation of an orderly world where disarmament will be possible. Our aims do not prepare for war—they are efforts to discourage and resist the adventures of others that could end in war.

That is why it is consistent with these efforts that we continue to press for properly safeguarded disarmament measures. At Geneva, in cooperation with the United Kingdom, we have put forward concrete proposals to make clear our wish to meet the Soviets half way in an effective nuclear test ban treaty—the first significant but essential step on the road towards disarmament. Up to now, their response has not been what we hoped, but Mr. Dean returned last night to Geneva, and we intend to go the last mile in patience to secure this gain if we can.

Meanwhile, we are determined to keep disarmament high on our agenda—to make an intensified effort to develop acceptable political and technical alternatives to the present arms race. To this end I shall send to the Congress a measure to establish a strengthened and enlarged Disarmament Agency.

IX. SPACE

Finally, if we are to win the battle that is now going on around the world between freedom and tyranny, the dramatic achievements in space which occurred in recent weeks should have made clear to us all, as did the Sputnik in 1957, the impact of this adventure on the minds of men everywhere, who are attempting to make a determination of which road they should take. Since early in my term, our efforts in space have been under review. With the advice of the Vice President, who is Chairman of the National Space Council, we have examined where we are strong and where we are not, where we may succeed and where we may not. Now it is time to take longer strides—time for a great new American enterprise—time for this nation to take a clearly leading role in space achievement, which in many ways may hold the key to our future on earth.

I believe we possess all the resources and talents necessary. But the facts of the matter are that we have never made the national decisions or marshalled the national resources required for such leadership. We have never specified long-range goals on an urgent time schedule, or managed our resources and our time so as to insure their fulfillment.

Recognizing the head start obtained by the Soviets with their large rocket engines, which gives them many months of lead-

time, and recognizing the likelihood that they will exploit this lead for some time to come in still more impressive successes, we nevertheless are required to make new efforts on our own. For while we cannot guarantee that we shall one day be first, we can guarantee that any failure to make this effort will make us last. We take an additional risk by making it in full view of the world, but as shown by the feat of astronaut Shepard, this very risk enhances our stature when we are successful. But this is not merely a race. Space is open to us now; and our eagerness to share its meaning is not governed by the efforts of others. We go into space because whatever mankind must undertake, free men must fully share.

I therefore ask the Congress, above and beyond the increases I have earlier requested for space activities, to provide the funds which are needed to meet the following national goals:

First, I believe that this nation should commit itself to achieving the goal, before this decade is out, of landing a man on the moon and returning him safely to the earth. No single space project in this period will be more impressive to mankind, or more important for the long-range exploration of space; and none will be so difficult or expensive to accomplish. We propose to accelerate the development of the appropriate lunar space craft. We propose to develop alternate liquid and solid fuel boosters, much larger than any now being developed, until certain which is superior. We propose additional funds for other engine development and for unmanned explorations—explorations which are particularly important for one purpose which this nation will never overlook: the survival of the man who first makes this daring flight. But in a very real sense, it will not be one man going to the moon—if we make this judgment affirmatively, it will be an entire nation. For all of us must work to put him there.

Secondly, an additional 23 million dollars, together with 7 million dollars already available, will accelerate development of the Rover nuclear rocket. This gives promise of some day providing a means for even more exciting and ambitious exploration of space, perhaps beyond the moon, perhaps to the very end of the solar system itself.

Third, an additional 50 million dollars will make the most of our present leadership, by accelerating the use of space satellites for world-wide communications.

Fourth, an additional 75 million dollars—of which 53 million dollars is for the Weather Bureau—will help give us at the earliest possible time a satellite system for world-wide weather observation.

Let it be clear—and this is a judgment which the Members of the Congress must finally make—let it be clear that I am asking the Congress and the country to accept a firm commitment to a new course of action—a course which will last for many years and carry very heavy costs: 531 million dollars in fiscal '62—an estimated seven to nine billion dollars additional over the next five years. If we are to go only half way, or reduce our sights in the face of difficulty, in my judgment it would be better not to go at all.

Now this is a choice which this country must make, and I am confident that under the leadership of the Space Committees of the Congress, and the Appropriating Committees, that you will consider the matter carefully.

It is a most important decision that we make as a nation. But all of you have lived through the last four years and have seen the significance of space and the adventures in

space, and no one can predict with certainty what the ultimate meaning will be of mastery of space.

I believe we should go to the moon. But I think every citizen of this country as well as the Members of the Congress should consider the matter carefully in making their judgment, to which we have given attention over many weeks and months, because it is a heavy burden, and there is no sense in agreeing or desiring that the United States take an affirmative position in outer space, unless we are prepared to do the work and bear the burdens to make it successful. If we are not, we should decide today and this year.

This decision demands a major national commitment of scientific and technical manpower, materiel and facilities, and the possibility of their diversion from other important activities where they are already thinly spread. It means a degree of dedication, organization and discipline which have not always characterized our research and development efforts. It means we cannot afford undue work stoppages, inflated costs of material or talent, wasteful interagency rivalries, or a high turnover of key personnel.

New objectives and new money cannot solve these problems. They could in fact, aggravate them further—unless every scientist, every engineer, every serviceman, every technician, contractor, and civil servant gives his personal pledge that this nation will move forward, with the full speed of freedom, in the exciting adventure of space.

X. CONCLUSION

In conclusion, let me emphasize one point. It is not a pleasure for any President of the United States, as I am sure it was not a pleasure for my predecessors, to come before the Congress and ask for new appropriations which place burdens on our people. I came to this conclusion with some reluctance. But in my judgment, this is a most serious time in the life of our country and in the life of freedom around the globe, and it is the obligation, I believe, of the President of the United States to at least make his recommendations to the Members of the Congress, so that they can reach their own conclusions with that judgment before them. You must decide yourselves, as I have decided, and I am confident that whether you finally decide in the way that I have decided or not, that your judgment—as my judgment—is reached on what is in the best interests of our country.

In conclusion, let me emphasize one point: that we are determined, as a nation in 1961 that freedom shall survive and succeed—and whatever the peril and set-backs, we have some very large advantages.

The first is the simple fact that we are on the side of liberty—and since the beginning of history, and particularly since the end of the Second World War, liberty has been winning out all over the globe.

A second great asset is that we are not alone. We have friends and allies all over the world who share our devotion to freedom. May I cite as a symbol of traditional and effective friendship the great ally I am about to visit—France. I look forward to my visit to France, and to my discussion with a great Captain of the Western World, President de Gaulle, as a meeting of particular significance, permitting the kind of close and ranging consultation that will strengthen both our countries and serve the common purposes of world-wide peace and liberty. Such serious conversations do not require a pale unanimity—they are rather the instruments of trust and understanding over a long road.

A third asset is our desire for peace. It is sincere, and I believe the world knows it.

We are proving it in our patience at the test-ban table, and we are proving it in the UN where our efforts have been directed to maintaining that organization's usefulness as a protector of the independence of small nations. In these and other instances, the response of our opponents has not been encouraging.

Yet it is important to know that our patience at the bargaining table is nearly inexhaustible, though our credulity is limited—that our hopes for peace are unfailing, while our determination to protect our security is resolute. For these reasons I have long thought it wise to meet with the Soviet Premier for a personal exchange of views. A meeting in Vienna turned out to be convenient for us both; and the Austrian government has kindly made us welcome. No formal agenda is planned and no negotiations will be undertaken; but we will make clear America's enduring concern is for both peace *and* freedom—that we are anxious to live in harmony with the Russian people—that we seek no conquests, no satellites, no riches—that we seek only the day when "nation shall not lift up sword against nation, neither shall they learn war any more."

Finally, our greatest asset in this struggle is the American people—their willingness to pay the price for these programs—to understand and accept a long struggle—to share their resources with other less fortunate people—to meet the tax levels and close the tax loopholes I have requested—to exercise self-restraint instead of pushing up wages or prices, or over-producing certain crops, or spreading military secrets, or urging unessential expenditures or improper monopolies or harmful work stoppages—to serve in the Peace Corps or the Armed Services or the Federal Civil Service or the Congress—to strive for excellence in their schools, in their cities and in their physical fitness and that of their children—to take part in Civil Defense—to pay higher postal rates, and higher payroll taxes and higher teachers' salaries, in order to strengthen our society—to show friendship to students and visitors from other lands who visit us and go back in many cases to be the future leaders, with an image of America—and I want that image, and I know you do, to be affirmative and positive—and, finally, to practice democracy at home, in all States, with all races, to respect each other and to protect the Constitutional rights of all citizens.

I have not asked for a single program which did not cause one or all Americans some inconvenience, or some hardship, or some sacrifice. But they have responded—and you in the Congress have responded to your duty—and I feel confident in asking today for a similar response to these new and larger demands. It is heartening to know, as I journey abroad, that our country is united in its commitment to freedom—and is ready to do its duty.

Introduction (36 p.)

THE FUTURE ENVIRONMENT: INTRODUCTION

1. Overview:

In June 1975, the Administrator of The National Aeronautics and Space Administration established a Study Group of twenty NASA scientists, engineers and managers to conduct a study of the role of civilian space flight in the U.S. in the period 1980-2000.

The study was to last one year and, although conducted by a NASA group, was expected to draw extensively on outside consultants and on expertise in disciplines not indigenous to NASA. The study was intended to be contextual; i.e., that is, the study topics were to be considered within the framework of other societal activities. This direction was set by two of the five objectives the Administrator established for the study:

1. "To identify social and economic challenges which can benefit from space."
2. "To relate goals and objectives of civilian space activities to national goals and objectives."

In recognition of its lack of expertise in economics, sociology, international affairs, and the future, the Study Group undertook a number of activities to bolster its knowledge and expand its horizons. A major effort along these lines was a contract with Forecasting International and The Futures Group which has resulted in this report to the Study Group. Included in this support to the Study Group, were extensive contacts with Working Group II (Future Environments) of the study team, with other members of the Group, and frequent participation in the Study Group discussions and deliberations on the relationships between space flight activities and the future economic, intellectual and other needs of the American Society.

Specifically, the basic contract required support, as follows:

a) Methodologies of technological forecasting

b) Lectures and seminars on contextual planning

c) Comments on the "system design" of the Outlook for Space Study

d) Literature searches and reports on the future

e) Participation in Study Group activities

and consultation on related matters as required. In addition, during the initial phases of the study, Forecasting International provided considerable support to the Technology Forecasting Task being performed by JPL for the OFS Study. Tutorial lectures on methodologies, existing technology forecasts and editorial assistance were furnished. This work is not reported here but was included, where appropriate, in the Working Group V (Technology)[1] report.

An early task of the Working Group II, and of the Study Group, was the examination of the various methodologies by which the future could be characterized and the choice of one for use as a framework for evaluating the differing contributions that various space flight activities could make in the future. Our early reports examined three approaches for consideration by the Study Group.[2,3,4] One developed several scenarios, as forecasts of

the future; another was an attempt to develop a set of national goals and objectives; and the third was a collection of brief essays on some potential crises that could radically change the future.

The scenarios, four in number, were derived from a "scenario map" in which the two dimensions were (a) the degree to which the U.S. Government interveres in domestic economic activities and (b) the degree to which the U.S. participates in the solution of international problems. Of the four scenarios possible with these two dimensions; (a) nationalist - laissez faire, (b) nationalist - planned, (c) cooperative - laissez faire, and (d) cooperative - planned, two were chosen for more detailed description; i.e., (a) and (d). Finally, in this approach, space programs which best fit each of the two future scenarios were discussed.

The second approach developed was to forecast and assess future space activities in the context of national goals and objectives. The immediate difficulty with this approach is that there does not exist in one place for all to know a statement of America's goals as a nation. The report surveyed the various studies and public polls on goals and objectives, selected a set which seemed most reasonable to the investigators and proceeded, in a semi-quantitative way, to weigh the contributions that space activities might make to meeting these various goals. The result was a matrix of numbers showing the contribution of space missions to weighted national goals.

The third approach was to develop a set of brief essays or descriptions of potential future crises which, it was deemed, would prompt policy analysis and policy-making by the Government. In the time frame of the next twenty-five years, the following crises were discussed: nuclear war, food shortages,

deterioration of the biosphere, imbalances in the distribution of wealth, shortages of mineral resources, energy sources and technology and inflation and international economics.

At the Study Group meeting at Marshall Space Flight Center in November 1974, these and other alternative approaches to examining the future were reviewed. The Study Group decided to proceed with an approach based on the potential crises essays, since, it was felt, this would provide the Group an indepth background on what was happening in society but would leave the Group itself free to evaluate space activities in the context of that background. The balance of the Forecasting International/The Futures Group study has been the preparation of a series of 20 essays on various selected issues in U.S. and World Trends.

The approach taken is outlined in the attached Figure 1. Six topics or Trends were selected: Non-renewable resources (including energy), Population and Food, etc. and within each of these Trends, a number of Issues are identified. One criterion for the choice of an Issue was that it might have, *a priori*, some direct or indirect implications for space flight in the future. In-depth analyses and narratives on each of the Issues were prepared. An overview or brief on each of the Trends was written.

This "trends and issues" approach was not intended to be comprehensive or in any way exhaustive. The specifics in one essay may conflict with those of another. There are many different views of what is changing, and how, in today's world. This approach was intended to provide the Study Group as wide-ranging and diverse a set of information as was possible within the time and resources available.

FIGURE 1

FUTURE ENVIRONMENTS: U.S. AND WORLD TRENDS

Non-renewable Resources:

- Minerals
- Energy - Energy and Growth

International Conflict:

- Economic Disparities
- Shared Resources
- Warfare

Population and Food:

- Fourth World
- Food and Fourth World Starvation
- Population Constraints on Growth
- Urbanization - U.S.
- Age Distribution - U.S.

Environment:

- Contamination of Environment
- Oceans
- Land Abuse
- Toxic Substances
- Modification of Biosphere

Economics:

- Inflation
- Capital Shortages

Individual and Society:

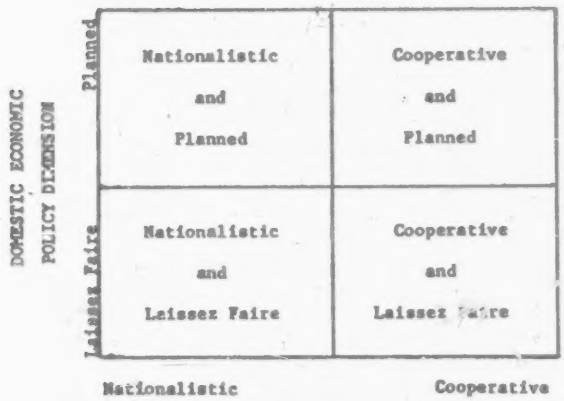
- Science/Technology Process
- Changing Concept of Equality
- Values
- Institutional Failure

2. Two Alternative Futures:

A frequently used approach to characterizing the future is that of scenario writing which has been defined as a "tool for creative thinking in preparing policy decisions."[5] Properly executed, it is not a forecast of the future, but a systematic way of combining technological, economic or political developments to obtain a feel for the long-range consequences. To illustrate the technique, and to provide alternative futures to which space flight planning might be referred, we have created two significantly different and self-consistent scenarios. The first step was to construct a "scenario map" (Figure 2), which graphically presents the major boundaries of the scenarios. Two major boundaries or continua were chosen as being the dominant descriptions of these futures.

FIGURE 2

A SCENARIO MAP



[5] Gerardin, L., "Study of Alternative Futures, A Scenario Writing Method," in a Guide to Practical Technological Forecasting, J. R. Bright and M. E. F. Schoeman, Editors, Prentice-Hall, Englewood Cliffs, N.J., 1973.

One boundary is the degree to which the *U. S. Government intervenes in domestic economic activities*. This ranges from one extreme of a laissez-faire economy to a totally planned and regulated economy. In the laissez-faire economy, the belief is that industrial activities, left to the forces of market supply and demand, can most efficiently and effectively provide the necessary goods and services to the society and that only this way can a high standard of living be attained. The planned economy is based on the premise that industry does what is best for industry, which may not coincide with the interests of society and the common good. Hence, the Government must actively and aggressively intervene to ensure that industry acts in accordance with proscribed societal standards.

The second dimension is the degree to which the U.S. participates in the solution of international problems. One extreme is the super nationalist chauvinism while the other extreme is total cooperation and leadership perhaps at the expense of domestic standards of living.

The four scenarios which result from these combinations are shown on the map and include:

nationalist - laissez faire
nationalist - planned
cooperative - laissez faire
cooperative - planned

For this exercise we have chosen to describe the nationalist - laissez faire and cooperative - planned scenarios. Many other dominant boundaries could have been chosen. It is difficult, of course, to determine the causal events of characteristics from which a societ evolves. We have chosen these boundaries because, to a very large extent, they embody just the kinds of choices that the nation is presently making.

The country is erratically moving upward (in the map) in the continuum describing U.S. intervention in the domestic economy. Recent actions such as the establishment of Amtrak, the Lockheed loan, efforts to assist Pan Am, the proposed Consumer Protection Agency, manipulation of the U.S. wheat market, wage and price controls, housing subsidies and Model Cities legislation emphasize this trend. At the same time, when efforts such as these do not immediately achieve their stated goals regardless of the reason, policy quickly moves in the other direction. Among these shifts are Postal Service reorganization, abolition of wage and price controls, revenue sharing, and abandonment of the "Great Society" legislation.

Overall, however, the trend over the past two decades has been towards *increased* government planning and intervention in the domestic economy. This is often thought of as a departure from traditional American philosophy and intent, but examination of U.S. economic history suggests that the dominance of government over industry is in fact a *return* to the original concepts of the Founding Fathers. The "robber baron" era was, in fact, an anomaly made possible by loopholes in several legislative changes. Fearful of potential corporate power, it was not until late in U.S. history that the corporate body could own land in its own right. Hence, the concept of the government manipulating the economy and dominating the productive forces for the common good is, contrary to folklore, a basic American tenet.

The path of the U.S. along the second continuum, the degree of international cooperation, has been much more circuitous. Clearly, the nation is not wearing the blinders of the isolationism so prevalent in the early part of the century. However, neither have humane considerations and cooperation become fundamental forces of foreign policy. This was dramatically evidenced

by the recent conditions of agricultural assistance to the starving nation of Bangladesh; in return for agricultural assistance the nation had to agree to forego the Cuban market for its only export — gunny sacks. Concomitantly, in real dollars, U.S. foreign aid has been decreasing, and as a percentage of total GNP, the U.S. allocates less to foreign aid than most other developed nations.

Economic policy has always been a tool of foreign policy — witness centuries of embargoes, tariff restrictions and the like. Recognizing the need for cooperative action in the face of resource shortages, grave international economic, pollution, famine and energy crises, the nation has yet to turn this recognition into any concerted action or policy plan. Nationalism is clearly not waning, and it is difficult to discern a conscious U.S. movement along this continuum.

The two boundaries for the scenarios were also chosen because they represent particularly sensitive issues for the acceptability of space missions. The space program, it can be argued, is necessary to maintain full employment, and this alone justifies substantial federal investment. The degree to which the federal government manipulates funding of the space program to achieve domestic goals may soon be a very real policy question.

Space missions can, of course, be used to satisfy international goals. In the 1960s, space activities were a dominant instrument of increasing U.S. prestige and world respect in the aftermath of the Cold War. Many of the international crises requiring international cooperative action — degradation of the biosphere, resource and energy shortages, famine, proliferation of nuclear weaponery — can all utilize different aspects of space capabilities.

The following scenarios are presented in summary form. The scenarios are self-consistent combinations of events depicting a likely world within the boundary definitions.

38-036 O - 84 - 92

SCENARIO A: NATIONALIST/LAISSEZ-FAIRE SCENARIO

Assumptions of the Scenario:

This scenario is based primarily on two basic assumptions:

> First, the U.S. government will rely more on industry for the maintenance of the economy. The market forces of supply and demand will determine the proper allocation of resources.
>
> Second, the U.S. government seeks to maintain the U.S. position as the most advanced nation in the world, both militarily and economically.

To avoid the danger of a distorted reality, it should be mentioned that the above set of government policies, if carried to the extremes, would find few supporters. Most people would agree that some government involvement in the domestic economy, and some involvement in international cooperation is valuable. However, many people believe there is too much government involvement already and that the proper balance must be reached. This scenario, then, attempts to point out some possible effects of a change from the present set of government policies towards a system of less government involvement. The fundamental attributes of this scenario are presented in Figure 3.

There are several present or potential situations that could trigger this form of policy change. First, the government has increasingly tried to manipulate the domestic economy to stabilize it, -- in terms of employment and production fluctuations and price stability, -- while still promoting a high rate of economic growth. The present situation of high inflation, high unemployment and declining "real" economic growth has certainly disenchanted many people with the government's economic policies. The stronger the measures taken by government (price controls), the more ineffective they seem to be (created shortages which increased inflation instead of curbing it).

FIGURE 3

IMPORTANT ATTRIBUTES: NATIONALIST/LAISSEZ-FAIRE SCENARIO

- Maintenance of many current institutions, i.e., nuclear family, religious institutions.
- Individual choice continues to be a social goal.
- High rate of economic growth.
- Profit motive is best method of resource allocation.
- Economic independence for U.S.
- Strong defense system is necessary to maintain the international balance of power.
- Self-achievement is still an important goal of most individuals.
- Technology is important for economic growth and increased well-being.
- Prefer local solutions, rather than federal intervention into social problems.
- Some reduction in civil rights is necessary for the benefit of society.
- Foreign aid continues to be tied to national goals.
- Continuation of ideological split between "East - West" powers.
- Relaxation of some environmental and consumer protection legislation to maintain a strong national economy.

Another government policy, its attempts to fight poverty, has also been viewed by many as an utter failure, for several different reasons. Many people resent supporting those who do not work. They perceive no real improvement in the poverty situation and do not wish to pay higher taxes for more ineffective programs, especially now with inflation so high and "real" incomes declining.

Also of concern to a great many people is the size of the federal government and the problem of "red tape". How can any organization so large and unwieldly be expected to operate effectively? Such an attitude creates popular pressure to limit the scope of government and to keep it more efficient, or at least maintain its functions in smaller, local units where there is knowledge and care for local problems.

Obviously it is unreasonable, given our present values and conditions, to assume that government involvement will, or should, dry up completely. What is generally called for is a re-ordering of priorities. Individuals must be responsible for themselves, the government cannot be. There are certain areas that government involvement is necessary for the survival of society.

Crime prevention is one of those areas. The rapid increase in crime and violence in the recent past, and the prospect for continued increases in the future are alarming. The costs of crime are borne by everyone in society through increased prices, insurance rates, fear, etc. (of course, the costs are higher for the victims), and most people do want to decrease crime prevention activities. In recent years, crime prevention has often stressed rehabilitation and changing the environmental influences of crime. To many people these methods have been complete failures; crime has increased and recidivism is

still high. This indicates a need for another policy change, a change to more stringent law enforcement.

If the political process is at all sensitive to the wishes of the people, and if the government is responsive and if the number of people with these views grows in the future, government involvement is likely to change in these directions.

In terms of international involvement, there are several conditions that will cause the United States to maintain a strong nationalist policy. For example, increased international competition has hurt many U.S. industries, causing the loss of many jobs. Many cooperative efforts benefit other countries more than the U.S., and sometimes involve sacrifices in the U.S. If the U.S. economy continues to suffer its present condition of economic doldrums, it is unlikely that many Americans will want to sacrifice their well-being for someone in another country. With jobs very difficult to find, few people are willing to give one up to foreign competition.

Another situation that is likely to increase the nationalism of U.S. foreign policies is the shortage of materials, including food and energy. Especially important is the likelihood of the formation of cartels to limit the supply and raise the price of essential materials, i.e., oil. The goals of resource independence and national security are likely to become more important, necessitating strong nationalist foreign policies to preserve our national well-being.

SCENARIO B: PLANNING/COOPERATION SCENARIO

Assumptions of the Scenario:

This scenario is based on two fundamental premises:

> the U. S. government actively intervenes in the U.S. economy to manipulate and direct the actions of the productive forces of the economy for the common good; and
>
> the U.S. government actively participates and cooperates with other nations and international organizations to assist in the solution of existing and prevention of potential international crises.

This scenario could logically develop from the present domestic and international troubles that the U.S. finds itself in. First, industry with some oversight and regulation by the U.S. government seems unable to sustain continued economic prosperity without severe economic fluctuations incorporating material shortages, insufficient supply and inadequate quality of goods and services, rampant inflation, and rising balance of payments deficits. At the same time, while the national economy is experiencing difficulty, many firms are enjoying excellent sales and history making profits. Hence, decision making becomes centralized in the federal government which increases its regulation and intervention to "guide" the performance of the economy along acceptable lines. This could include stringent, yet realistic, wage and price controls; allocation of existing supplies of scarce resources and stockpiling supplies for the future; government takeover of "true monopolies" such as utilities, transportation and communication firms; and institution of excess profits taxes and elimination of depletion allowances. The fundamental attributes of this scenario are illustrated in Figure 4.

At the same time great control would be exercised over the nature of the goods and services produced and the methods by which they could be produced and distributed. This would include stringently enforced quality

FIGURE 4

OTHER ATTRIBUTES: PLANNED/COOPERATIVE SCENARIO

- Tolerance of new and different lifestyles.
- Moderate economic growth.
- Rigid consumer and environmental legislation.
- No self-sufficiency in energy.
- Possible fear and distrust of U.S. as an international "do gooder".
- Increases in per capita real affluence.
- Food/Energy/Resource crisis present but considerably less severe.
- Active multi-country exploration and exploration of the oceans.
- Economic interdependence among developed nations and between underdeveloped and developed nations.
- Continued worldwide inflation.
- Decrease in use of military force and interdependency creates fear of using economic force.
- Recognition that social problems require institutional and political remedies rather than technological panaceas.
- Decrease in per capita domestic resource use and waste generated.

and safety regulations and standards for *all* products, rigid pollution abatement requirements without exception, consumer legislation governing the integrity of firm's conduct, provision for damages to the consumer as a result of industrial malfeasance, strict regulations governing occupational safety and protection of the employee.

Internationally, the U.S. would actively assist in solving and preventing international crises by contributing two of the nation's greatest strengths: its managerial and technical capability as well as substantial financial assistance. Individuals representing the nation's best would be "loaned" full time at federal expense to international organizations charged with attention to a given problem. International cooperation would include automatic large scale disaster relief; mutual interdependence for supplies of scarce resources, especially food and energy; U.S. medical, technical, and population planning assistance; and a forum with supralegal powers for resolution of conflict and monitoring of the proliferation of weaponery.

Concomitantly, the government would assume more and more responsibility for the individual and the scenario implies implementation of large scale social welfare programs. Among them would be income redistribution through a negative income tax, taxing of the super rich, and abolition of tax shelters; government financial insurance including medical and dental health care, retirement insurance; day care centers; food and housing allowances to offset inflationary trends (no household would have to pay in excess of 45% of their disposable income for minimum standards of food and housing); government subsidies to education, revitalization of the cities, medical health care and research, and so forth.

Individual behavior would be deregulated and there would be a great deal of choice among life styles, living arrangements and work relationships.

The Implications of this World:

What does this world mean? First, while economic growth will continue at moderate levels, it will be an inflationary world at the outset because of the large amounts of government spending. Over time, however, the inflationary aspects could be dampened through tax reform and income redistribution so that government programs could be financed through general revenues.

Secondly, the scenario implies that the institutions will be created that can effectively provide the necessary national and international mechanisms for the scenario events to occur. This is probably the weakest link of the scenario. The scenario implies threats to existing power bases such as industry leadership, political patronage, even individual national identity would be subservient to international liaisons and organizations. Because of the threats to existing power bases, it will be extremely difficult to move completely into this path. Institutional insufficiency is the major difficulty. Only through creation of effective and responsive bureaucracies can this scenario be successful.

Thirdly, the scenario also implies a great deal of individual freedom of action and choice. There are many incentives built into it *not* to join the labor force. This could have exceedingly disrupting implications not only in terms of inadequate supplies of available labor but also increasing demands for government services.

Finally, the world implies a great deal of support for space activities, both to ensure domestic full employment and to assist in international activities. It is likely that these efforts would be largely government-financed through government agencies rather than as sole ventures of private industry.

This world may be inherently unstable. The threats of inflation and the drains that the social welfare programs and international cooperation would entail may be too severe. The success and stability of this scenario would depend upon several factors:

- institutional reform and creation of an effective and responsive bureaucracy;
- income redistribution to prevent massive deficit financing and, hence, rampant inflation;
- adequate incentives to participate in the labor force;
- form for resolution of international conflict.

3. Forecasts and Assessments of Future Civilian Space Activities:

a) The Development of National Goals

At best, the concept of national goals is ambiguous, at worst controversial. There is no national consensus about priorities, no set of national goals neatly summarized in a document. Indeed, the great discussion about "re-ordering of national priorities" has made it clear that no consensus exists concerning national objectives and their integration in a set of ordered priorities. Only through analysis of actions by the Congress, the Executive branch of the government, the business community and the private consumer sector, can one discern a phantom set of national goals and priorities implied in those actions.

It has been argued[5] that national goals can be inferred from the level of expenditure allocated to a given area. The argument goes as follows.

---

[5] Lecht, Leonard A., Changes in National Priorities During the 1960s: Their Implications for 1980, (National Planning Association, Washington, D.C.), 1972.
Lecht, Leonard A., Goals, Priorities and Dollars: The Next Decade (The Free Press: New York), 1966.

The allocation of the total efforts of the nation at any given point in time should indicate the momentary sense of priorities, and changes in allocations over a period of time should indicate changing trends in those priorities. The best available common denominator for the allocation of the nation's efforts is the dollar expenditure toward each of the phantom goals.

In the aggregate, U.S. dollar expenditures represent the blending of judgments on national priorities by government, business and private consumers. The government responds to perceived needs, and through debate and compromise, charts new directions and changes in priorities. The business community, labor unions and private consumers act on the basis of what they perceive to be in their best interests and their actions collectively are a measure of their current priorities with a discounted future interest.

Elements of national expenditures which comprise the Gross National Product (GNP) thus constitute one measure of priorities for the nation as a whole.

However, level of expenditures may more accurately reflect a condition of the *past*, rather than a statement about where the nation wishes to be. Using expenditure levels for 1969 and 1962 one can see (Figure 4) that there were shifts in the aggregate levels of expenditure, the relative ranking -- priorities, if you will, of the different categories did not shift dramatically.

In establishing a set of national goals, it is important to develop a quantifiable statement of where the nation wishes to be in each area so that progress to or away from that goal can be monitored. Dollar expenditures are often the *means* to achieve the goal, but in and of themselves do not

reflect a goal. Hence, in this task a great deal of effort was devoted to determining what the nation does wish to accomplish. This was done by reference to the existing goals, literature,[6] interviews and polling.

A list of the national goals obtained by this process is given in Figure 5. All national goals, of course, are not equal. Earlier efforts to determine priorities among competing goals were based on levels of expenditures of the past. In the effort here, we have asked the question: "In view of where we are today, to what activities should the nation's efforts be devoted?" Using a modified Delphi approach questioning a panel of experts and nonexperts, the relative weights and rankings shown in Figure 6 were determined. These weights were then used in the later matrix analysis. These weights, of course, are highly subjective and the public's view of them may change frequently and rapidly. For instance, the goal category "agriculture and food" was considerably higher in urgency due to recent concern with the world food supply. Any solution to this problem would undoubtedly lower the priority of that goal.

FIGURE 5

EXPENDITURES FOR SOME GOAL AREAS
1962 Versus 1969
(Billions of 1969 Dollars)

Goal Area	Expenditures		Rank	
	1962	1969	1962	1969
Housing	37	35	8	9
Urban Facilities	47	59	2	6
National Defense	67	79	1	1
Social Welfare	46	71	3	2
Health	44	64	4	3-4
Education	42	64	5	3-4
Transportation	39	62	7	5
R&D	21	27	10	10
Natural Resources	7	10	11	11
Environment		6		12
Foreign Aid	6	5	12	13
Communication	22	37	9	8
Farm Product	40	51	6	7

b) Relationship Between Space Activities and National Goals

We drew up a list of possible space missions, functions, and activities (Figure 7) which might be conducted now or in the next two and one half decades. While an attempt was made to eliminate redundancies, no attempt was made to distinguish between new and innovative missions and missions which are currently being planned or studied.

It should be noted that the items in the list are not mutually exclusive. In some cases, a combination of items may be mutually supportive. For example, weather satellites can provide data for weather forecasting, and the weather forecasts could then be communicated to large numbers of individuals by broadcast satellites.

FIGURE 6

NATIONAL GOALS - A RANK ORDERING AND WEIGHTING

Goal	Rank	Weight
Agriculture and Food	1	8.4
Natural Resources and Material Supply	2	6.8
Housing	3	6.7
Environmental Quality & Pollution	4	6.5
Education	5	6.3
Jurisprudence	6-7	5.9
National Economy	6-7	5.9
Law and Order	8	5.6
Medicine & Health	9	5.4
Defense	10-11	4.8
International Cooperation	10-11	4.8
Social Interaction	12	4.3
Urban Design & Environment	13	4.2
Foreign Aid	14-16	3.4
Cultural Activities	14-16	3.4
Economics of the Individual	14-16	3.4
Transportation	17	2.9
Disaster Prediction and Control	18	2.6
Recreation and Leisure	19	2.4
Public Utilities	20	2.3
Communication	21	2.2
Maintenance of the Bureaucracy	22	1.6

We then carried out a cross support analysis of the identified space missions/functions/activities, and their contribution to national goals. The possible missions were treated both as independent variables and as dependent variables. That is, two kinds of cross support analyses were performed.

The first analysis was conducted by assigning numbers (representing judgments of the degree of cross support) in answer to the following questions: "Assuming this particular mission were conducted successfully, to what degree would its results support the achievement of the particular national goal?". Numbers were assigned according to the following scale:

1 = little or no support

2 = some support

4 = considerable, significant degree of support

8 = major support

Because of the difficulties which can arise with combining negative and positive numbers, no negative numbers were utilized.

The second analysis was conducted in a similar manner, representing a response to the following question: "Assuming the United States makes a commitment to this particular goal, to what degree will this commitment tend to support this particular space mission?". Numbers were assigned as in the first analysis.

The national goal areas previously defined were used in the cross support analyses.

c) Mission Support for Equally Weighted Goals:

The detailed results of the cross support analysis (matrix worksheets) are given in the September 28, 1974 report. Figure 7 summarizes the results

FIGURE 7

RANK ORDERING OF MISSIONS

(Assuming Goals are Equally Weighted)

	PANEL 1	PANEL 2
1.	Pollution Monitoring	Disaster Warning
2.	Resource Mapping/Monitoring	Weather, Climate Control
3.	Data Network	Resource Mapping/Monitoring
4.	Reflectors	Broadcast Satellite
5.	Broadcast Satellite	Data Network
6.	Weather, Climate Control	Common Carrier
7.	Disaster Warning	Meteorological
8.	Meteorological	Multiple Access
9.	Atmospheric Physics	Navigation/Traffic Control
10.	International Missions	Aerodynamic Research
11.	Multiple Access	Hazardous Material
12.	Navigation/Traffic Control	Pollution Monitoring
13.	Data Commercialization	Satellite Servicing
14.	Common Carrier	Aircraft Noise Reduction
15.	Colonization	Reflectors
16.	Aircraft Noise Reduction	Orbiting Power Station
17.	Hazardous Material Tracking	Private Communications Satellite
18.	Orbiting Power Station	Atmospheric Physics
19.	Ionospheric Physics	International Mission
20.	Defense System Monitoring	Health Treatment
21.	Manufacturing	Data Commercialization
22.	Aerodynamics Research	High Energy Physics
23.	High Energy Physics	Defense System Monitoring
24.	Private Communications Satellite	Solar, Other Measurements
25.	Waste Disposal	Ionospheric Physics
26.	Health Treatment	Waste Disposal
27.	Electromagnetic and Particle Experiments	Electromagnetic and Particle Experiments
28.	Intra-solar System Probes	Paired Probes
29.	Astronomy	Assembly
30.	Paired Probes	Colonization
31.	Extra-solar System Probes	Manufacturing
32.	Satellite Servicing	Meteor Analysis
33.	Extraterrestrial Communication	Astronomy
34.	Solar, Other Measurements	Intra-solar System Probes
35.	Meteor Analysis	Extraterrestrial Communication
36.	Assembly	Extra-solar System Probes

by rank ordering the missions according to the total support each provides for the national goals.

Although there are differences in the two independent rankings, considerable agreement exists. For example, four of the top six missions are common to both rankings.

- weather, climate control
- resource mapping/monitoring
- data network
- broadcast satellite

Out of the top one-third (12) missions, the two rankings list eight common missions. In addition to the above four, these include:

- disaster warning
- meteorological satellites
- multiple access communications satellites
- navigation/traffic control

The differences in rankings may be attributed to one or a combination of the following factors: unintentional biases based on perceived feasibility, differences in perceived opportunities and in future values, and different judgments as to the strengths of perceived impacts.

d) Relationship Between Weighted Goals and Missions:

The mission to goal analysis to this point has assumed that all national goals have the same weight. If we add the dimension of differences in priorities among the goals, as shown earlier in Figure 6, we find that space missions are able to substantially contribute, in theory, to the achievement of some of the highest priority goals. The Figure 8 below indicates that environmental quality and agriculture and food receive the greatest contribution from space missions.

FIGURE 8

NATIONAL GOALS RECEIVING SUPPORT FROM CIVILIAN SPACE MISSIONS

Goal	Total Space Contribution
Agriculture and Food	2368.8
Natural Environment	2132.0
Natural Resource and Material Supply	1768.0
Urban Environment	1699.2
Health and Medicine	1609.2

When consideration is made of the priorities among the goals, the rank orderings of the missions are somewhat different than those rankings which assumed equal weights. The highest ranking missions are:

- Pollution monitoring
- Resource Mapping/Monitoring
- Data Network
- Broadcast Communications

4. Prospective Crises: Some Challenges to Planning

This section describes another dimension of planning for the future; i.e., the understanding of potential future crises which might face the U.S. over the next decades, and an examination of the relative importances of these crises in terms of their impacts on society. The crisis orientation is an important point of departure in creative thinking about the future because it is the nature of our society to respond to crises.

For example, in describing our time to a visitor from the past, we would almost certainly include the energy crisis, the Middle East crisis, the Watergate crisis, and the inflationary crisis in our list of descriptors of the present. Without focusing on potential crises, as depressing as that might be, our descriptions of the future would be totally inadequate; more importantly, little would be known of the immediate need for creative and decisive policy-making. We talk of crises, of unpleasant futures, to prompt policy analysis and policy-making where it may count the most.

Inevitably, this approach presents arguments which will be discouraging. If the projection of crises are believable, the import will be one of Gotterdammerung. But the future is not likely to be as dismal as these essays might indicate for several reasons:

- The crises are plausible but not necessarily probable.
- The consequences, as mentioned above, may be seen in a different perspective than we think.
- We have focused only on crises not, their opposite. (For reasons which are not very clear, it is easier to visualize odious situations than desirable states).
- As the probability of a crisis increases, it is more likely that action will be taken in an attempt to avert the evolving situation.
- Some of the crises discussed here are apparently casually connected; correction of one may mitigate others.

Yet running throughout the discussion is the suggestion that the coming twenty-five years is indeed a time of climax, a time of issues of unprecedented magnitude and permanence. Food shortages, materials and energy availability, and monetary instability: all of these issues have affected society before; what is new is their potential simultaneity and world scope. Certainly within these crises, and their concomitant consequences, are the seeds of the future.

Important changes of the next two and a half decades seem likely to come not only from science and technology, from the waxing and waning of institutions responding to external pressures and internal decay, from policies of Governments and the values and actions of groups of people, but from the unexpected and deleterious actions of the socio/economic/political system. These unexpected system responses can trigger crises.

"Crisis" can have several definitions; the meaning employed in this essay is:

> A crucial situation; a situation whose outcome decides whether possible bad consequences will follow.

Thus, this section on future crises deals with potential situations which may have grievous consequences. At least two degrees of uncertainty are involved in each crisis: the inevitability of the crisis itself and the likelihood that the anticipated consequences will flow from the crisis situation. With respect to the former uncertainty, each crisis is defined in terms of trends already well-established, which, through their coincidence and reinforcement make the crisis, if not likely, at least plausible. The second uncertainty, that of the consequences of the crisis, is more difficult. Society has a marvelous propensity to adapt, and situations which seem onerous and threatening to us may, to some future society, seem part of the natural order and a desirable state of affairs. For example, a chronic energy shortage is perceived by many economists as a potential cause of inflation, recession and perhaps economic depression. Yet this image assumes a continuation of current lifestyles; it is possible that society, faced with high energy costs, will change to lifestyles requiring lower energy inputs. Thus the crisis, energy shortage, may have occurred, but its consequences will be viewed with quite a different feeling in retrospect than

some view it prospectively. There is no alternative, however, to using current values in projecting crisis.

It is one thing to suggest that recognizing key future crises can form an interesting forecasting model; it's quite another to develop a metric for selecting a subset of issues to address. John Platt, in his paper "What We Must Do," suggested as an index of crisis intensity, a measure which included the number of people likely to be affected, the degree of this effect, and the time until the effect is realized. In his scaling, a grade 1 crisis represented total annihilation; a grade 2 crisis, great destruction or physical, biological, or political change; a grade 3 crisis, almost unbearable world tension, and so on.[7]

Recent work in technology assessment has added other criteria to Platt's list. One might include "relative confidence" or certainty in the degree of effect of the crisis. For example, a potential crisis which is very uncertain and yet which could have a tremendous effect might be accorded a very high priority. The list might include "reversibility" (that is, the ability for any policy to reverse the consequences of the crisis -- an irreversible crisis is much worse than a reversible one). Finally, "responsibility" could be an important priority-ordering criterion: does the responsibility for curing the crisis lie clearly within some existing institution's mission? The responsibility criterion also becomes important when more than one institution thinks it has the job of correcting a problem, because more often than not, jurisdictional disputes will arise that can inhibit clear-cut and decisive action.

---

[7] John Platt, "What We Must Do," Science, Vol. 166, No. 3909 (November 28, 1969), pp. 1115-1121.

Thus the dimensions by which the severity of a future crisis might be judged (although these criteria are clearly not of equal weight) include:

1. Number of people affected.
2. Degree of effect.
3. Probability of timing of the impact.
4. Reversibility.
5. Responsibility.
6. Confidence in judgments.

A most important crisis would be one in which a large number of people are likely to be severely affected, almost immediately, in an irreversible way, with no institution clearly having responsibility for detecting or curing the problem. This situation would obtain at either of two levels of confidence: great certainty in the judgments, or great uncertainty.

What then are some of the issues which meet these criteria? While others could certainly extend this list considerably, our nominations for the top set are shown in Figure 9.

We made an attempt to understand the relationships among the crises on this selected list, using the cross-impact matrix technique.

Figure 10 is a cross-impact matrix of crises discussed in this section. As in the case of all cross-impact matrices, this figure shows the relationships which appear to exist among the variables considered. The seven postulated crises appear on both the ordinate and abscissa. The numbers in the cells of the matrix are in answer to the question:

> If the crisis shown in the ordinate occurs, how will the crisis, shown in the abscissa, be effected?

FIGURE 9

SOME IMPORTANT CRISES

CRISIS	CRITERIA					
	NUMBER OF PEOPLE AFFECTED	SEVERITY OF THE EFFECT	PROBABILITY	REVERSIBILITY OF THE COURSE OF DEVELOPMENT OF THE CRISIS	RESPONSIBILITY	CONFIDENCE IN JUDGMENT
Nuclear war	Very Large	Very Great	Very Low	Possible	Diffuse	Moderate
Severe food shortages	Very Large	Very Great	High	Possible	Diffuse	High
Deterioration of the biosphere	Very Large	Moderate-Great	Moderate	Difficult	Diffuse	Low
Imbalances in the distribution of wealth	Very Large	Great	Very High	Very Difficult	None	Moderate
Shortages of mineral resources	Large	Moderate-Great	Very High	Very Difficult	None	High
Energy shortages	Moderate-Great	Moderate-Great	Very High	Very Difficult	Diffuse	High
Inflation and monetary instability	Moderate-Great	Moderate-Great	Very High	Very Difficult	None	Moderate

FIGURE 10

CROSS-IMPACTS AMONG CRISES — OCCURRENCE

IF THESE OCCUR ⇩ / THESE ARE AFFECTED AS SHOWN IN THE MATRIX ⇨	Nuclear War	Food Shortages	Deterioration of the Biosphere	Imbalances in the Distribution of Wealth	Shortages of Mineral Resources	Energy Shortages	Inflation, Capital Shortages
Nuclear War		-4	+4	?	?	?	-2
Food Shortages	+2		+4	+4	0	+2	+2
Deterioration of the Biosphere	0	+2		0	+1	+1	+2
Imbalance in the Distribution of Wealth	+2	+1	0		+3	+3	+3
Shortages of Mineral Resources	+2	+1	+1	-2		+2	+2
Energy Shortages	+2	+3	+2	-2	0		+3
Inflation, Capital Shortages	+1	+2	0	+2	+2	+2	

Key: +4 = Greatly intensified
0 = No effect
-4 = Greatly mitigated
? = Uncertain

A +4 indicates a judgment that the dependent crises will be greatly intensified. a -4 indicates the judgment that the dependent crisis will be greatly mitigated.

The preponderance of + signs in the matrix indicates that by and large the occurrence of any of the crises seems likely to intensify the crises which have not yet been realized. More specifically:

- All of the crises lead in the direction of war, and except for war itself, in the direction of inflation and capital shortages.
- Imbalance in the distribution of wealth seem likely to be intensified by food shortages, inflation and capital shortages, but are mitigated by shortages of mineral resources and energy shortages, particularly if energy supplies and mineral resources are owned by currently impoverished countries.

Figure 11 shows the other side of the coin. In this cross-impact matrix, it is assumed that the crises are corrected and the matrix displays the consequences of these corrections. For example, the numbers contained in the cells of the matrix answer the question:

> If the crisis shown in the ordinate were to be prevented, how would the other crises be affected?

In this case, the matrix shows a preponderance of minus signs, showing that correction of the crises generally leads to improvement in other areas as well. However, the intensities contained in this matrix as compared with the previous matrix shows that the situation is probably non-linear; that is, the occurrence of one crisis seems more likely to trigger other crises than the curing of one crisis is likely to cure other crises. For example, eliminating the possibility of nuclear war probably has little affect on any of the other crises except food shortages which may be intensified.

FIGURE 11

CRG IMPACTS AMONG CRISES — NONOCCURRENCE

IF THESE DO NOT OCCUR ⇩ / THESE ARE AFFECTED AS SHOWN IN THE MATRIX ⇨	Nuclear War	Food Shortages	Deterioration of the Biosphere	Imbalances in the Distribution of Wealth	Shortages of Mineral Resources	Energy Shortages	Inflation, Capital Shortages
Nuclear War		+2	0	0	0	0	0
Food Shortages	+1		-3	-4	0	-1	-1
Deterioration of the Biosphere	0	0		0	0	0	-2
Imbalance in the Distribution of Wealth	-2	-4	-1		-1	-1	?
Shortages of Mineral Resources	-1	0	0	+2		0	-3
Energy Shortages	-1	-2	-3	+2	-3		-3
Inflation, Capital Shortages	-1	0	0	-1	0	0	

Key: +4 = Greatly intensified
0 = No effect
-4 = Greatly mitigated
? = Uncertain

Curing of deterioration of the biosphere seems to be ineffective in all other areas except inflation and capital shortages which it will help (since the need for spending for anti-pollution devices will be diminished). Cross impacts of specific note include:

- Curing of imbalances in the distribution of wealth will greatly mitigate food shortages since developing countries would be able to purchase agricultural inputs and food; in other words; the free market system could be brought into play to help avoid starvation.

- Energy shortages reduce the intensity of deterioration of the biosphere since freely available energy could be used to clean the environment.

- Similar abundant energy can be substituted in many instances for short raw materials; therefore the availability of energy mitigates the potential mineral resource crisis.

Anticipating crises, understanding their nature to the degree possible, and moving to implement policies which mitigate them, would seem to be an important thrust for the political sciences in the next two decades. We need, following the suggestion of John Platt, a metric for crises; and following the suggestion of Hal Linstone, a system of crisis discounting akin to cash flow discounting which could help sort out priorities for the nation.

The dimensions of these and other potential crises are discussed in the next section which constitutes the bulk of this report since the Study Group decided that its approach to characterizing the future would be based on the examination of certain Trends and Issues facing the nation.

5. Conclusions

There is no doubt that the next twenty-five years will be a period of crisis and challenge. The principle components of the "problematique" and the idea that the world is in the midst of a major transition in its historic

developmental patterns are familiar to almost everyone. The contents of this report, particularly the essays on Trends and Issues, have provided some measures of the dimensions of the problems, food, population, warfare, energy, pollution, etc. and their intense interactions. The core issue may well be stated as *the maintenance of an equitable and dynamic equilibrium between world population and world resources.* This issue is not new; Malthus advanced it, albeit pessimistically, at the beginning of the 19th century. What is new, in addition to the exponentially growth of the crises, is the profound changes in the world's *perceptions of equity and social justice,* which would require, if pursued, a redistribution of the wealth and basic changes in the rules of the "system". It is not reasonable to expect that a system in which "the rich get richer and the poor get poorer" will survive without the imposition of imperialism on the international scene and a paternal fascism in domestic affairs.

The alternatives are the challenges that face the nation and the world.

It became clear to us during the course of this study on the Outlook for Space that space flight with its global perspective, its ability to tie nations and peoples together, and its unique capabilities to illuminate man's universe and his nature has an enormous, untapped potential for contributing to the solutions of the world's problems and to meeting its needs.

With tools such as space flight, mankind has the means to make the difficult transition into the twentieth century. He needs only the will and determination.

SPECIAL ANALYSIS K

RESEARCH AND DEVELOPMENT

This analysis covers the funding of research and development across all departments and agencies with R&D programs of $10 million or more, representing over 99% of total Federal funds for R&D. It consists of two sections. The first highlights the R&D policies and trends in the 1984 budget. The second describes in more detail the R&D programs of 13 agencies whose R&D obligations individually exceed $150 million.

Part I. Highlights

Total Federal funding for research and development, including R&D facilities, is proposed at $47.0 billion in 1984, an increase of $6.9 billion or 17% above the 1983 level of $40.1 billion. Included within the overall R&D funding is support for the conduct of basic research, estimated to increase by 10%, from $6.0 billion in 1983 to $6.6 billion in 1984, including an 18% increase in programs of the National Science Foundation.

The Federal Government funds R&D activities to serve two broad purposes:

- To meet specific Federal Government needs—where the principal user of the R&D is the Government itself—for example, to ensure a strong national defense;
- To meet broad national needs—where the Federal Government supports R&D that the private sector lacks incentive to invest in adequately, in the national interest—to help assure the strength of the economy and the quality of life for all people. Included in this category are, for example, agricultural and health research; support of basic research through programs of the National Science Foundation and the general science programs of the current Department of Energy; and the pursuit of selected long-term energy technologies, such as magnetic fusion.

The 1984 budget continues to reflect the established policies of the Administration in funding R&D but further strengthens support in areas of major Federal responsibility. It provides for:

- Major increases across all R&D programs of the Department of Defense;
- A significant increase in Government-wide support of basic research with emphasis on support of research in the physical

Reproduced from Special analyses, budget of the United States Government, fiscal year 1984. Washington, G.P.O., 1984. p. K1-K28.

sciences and engineering. Advances in these fields are key to future national defense and the long term competitiveness of the U.S. economy, particularly in high technology industries.

- A number of major new initiatives, particularly in energy-related programs, currently in the Department of Energy, and in NASA that will significantly enhance the research productivity of the Nation's scientific community especially in basic research. These include a new center for materials research at the Lawrence Berkeley Laboratory, expansion of the National Synchrotron Light Source at Brookhaven National Laboratory, a new colliding beam facility at the Stanford Linear Accelerator Center, and a numerical aerodynamic simulation capability at NASA's Ames Research Laboratory.
- Continued reductions in Federal support of nearer-term R&D and demonstration programs (e.g., in energy technologies). For such programs the private sector, not the Federal Government, has the expertise and capability to select and fund the advancement of technologies that can be successfully brought into the marketplace. To complement private sector efforts, the Federal Government's role is primarily to create an economic climate conducive to private investments, through such measures as tax incentives and reductions in the burden of regulations. Federal Government investments should be limited to longer term research and technology support which the private sector does not have the economic incentive to provide for adequately to serve the national interest.

The Administration will further seek, in 1984, to make more effective use of increased research funds, particularly in the basic sciences to:

- Attract the highest caliber scientists and engineers, particularly young faculty members, into research and encourage and support them in their careers. These efforts will assist in ensuring a high quality scientific workforce to meet needs of the Nation both in the near and the long term;
- Encourage greater and more creative interaction among university, Government and industry scientists to bring the Nation's best scientific expertise together in addressing the most challenging scientific and technical problems and opportunities; and
- Upgrade the scientific instrumentation of universities to enhance productivity and excellence in research and the training of scientists and engineers.

The 1984 budget also includes proposed efforts by the NSF and the Department of Education to improve the teaching of science and mathematics in the Nation's secondary schools. Though not covered in this analysis, these efforts will help in improving the

capability of the future work force to contribute to economic growth in an increasingly technological society.

Total obligations and outlays for the conduct of all Federal R&D programs and for related facilities are shown in Table K-1.

TABLE K-1. TOTAL FEDERAL FUNDING FOR CONDUCT OF R&D AND RELATED FACILITIES

(In billions of dollars)

	Obligations			Outlays		
	1982 actual	1983 estimate	1984 estimate	1982 actual	1983 estimate	1984 estimate
Conduct of R&D	36.4	38.9	45.8	34.5	37.7	42.7
R&D Facilities	1.2	1.2	1.2	1.3	1.2	1.1
Total	**37.6**	**40.1**	**47.0**	**35.8**	**38.9**	**43.8**

CONDUCT OF RESEARCH AND DEVELOPMENT

The 1984 budget includes $45.8 billion in obligations for the conduct of R&D, an increase of $6.9 billion or 18% over 1983. Highlights of the programs of the major R&D agencies that account for 93% of the proposed obligations for the conduct of R&D by all agencies are presented below:

- **Department of Defense (DOD).**—Obligations for the conduct of R&D by DOD are estimated at $29.9 billion in 1984, an increase of $6.7 billion or about 29% above 1983. This represents 65% of the total Federal funds for R&D proposed for 1984. The increased funds are proposed for R&D largely related to advanced strategic systems such as the Peacemaker and Trident II ballistic missiles. In addition, the Department would also provide for increased emphasis on basic research in such areas as materials and microelectronics, and advanced technology development in such areas as very high speed integrated circuits.
- **National Aeronautics and Space Administration (NASA).**—Obligations for the conduct of R&D by NASA are estimated at $2.5 billion in 1984, about equal to 1983. The 1984 request would allow NASA to pursue a vigorous program of space science, applications, and advanced technology for space projects and future aircraft. The 1984 budget proposes several new initiatives such as a Venus Radar Mapper to provide a map of the surface of Venus, a numerical aerodynamic simulation capability, and development of advanced composites for large aircraft structures. Previously approved projects such as the Space Telescope, and the Advanced Communications Technology Satellite (ACTS) will be continued.

- **Energy Related Activities.**[1]—Obligations for the conduct of R&D programs currently in the Department of Energy are estimated at $4.7 billion, about the same as in 1983. However, basic research funding would be increased by $160 million, or more than 18% over 1983. Increases are proposed to strengthen the nuclear weapons R&D program, to enhance support for long-term energy research, and to maintain a strong national basic science effort in high energy and nuclear physics. These increases are offset by proposed reductions in support for nearer-term energy technologies such as fossil and solar demonstrations, where reliance is placed on private sector support.
- **Department of Health and Human Services (HHS).**—Obligations for the conduct of R&D in HHS are proposed for an increase of $100 million, from $4.3 billion in 1983 to $4.4 billion in 1984. This represents a 12% increase over the two year period, 1982-1984. The National Institutes of Health (NIH) account for about 87% of total R&D funding by HHS. An increase of $71 million above 1983 is proposed for R&D programs of NIH, including basic research in the biomedical sciences.
- **National Science Foundation (NSF).**—R&D obligations by NSF are expected to increase by $180 million, or 17%—to $1.2 billion in 1984. The additional funds will largely be devoted to strenthening support of basic research in the mathematical and physical sciences and engineering, that support long-term economic growth. This increase also provides additional funds for upgrading research instrumentation at universities.

Table K-2 summarizes Federal support for the conduct of R&D by agency.

CONDUCT OF BASIC RESEARCH

The 1984 budget continues to reflect the Administration's view that investments in basic research across all scientific disciplines are critical to the long-term economic strength of the Nation and the well-being of its citizens. Basic research in such fields as mathematics, physics, chemistry, and engineering provides the foundation, in the long term, for a strong national defense, and leads to new discoveries and new technologies and industries that enhance U.S. competitiveness, employment and the quality of life.

Federal Government funding for the conduct of basic research is included within the total support for the conduct of R&D. In 1984, obligations for the conduct of basic research are estimated at $6.6 billion, an increase of $594 million or 10% above the 1983 level.

[1] These programs, along with other activities currently funded by the Department of Energy, will be proposed for reassignment to other Executive departments and agencies.

TABLE K-2. CONDUCT OF RESEARCH AND DEVELOPMENT BY MAJOR DEPARTMENTS AND AGENCIES

(In millions of dollars)

Department or agency	Obligations			Outlays		
	1982 actual	1983 estimate	1984 estimate	1982 actual	1983 estimate	1984 estimate
Defense-Military Functions	20,576	23,179	29,882	18,201	21,847	26,844
Energy Related Activities	4,758	4,712	4,713	4,974	5,012	4,911
Health and Human Services	3,935	4,316	4,416	3,978	4,262	4,339
(National Institutes of Health)	(3,432)	(3,771)	(3,842)	(3,438)	(3,737)	(3,808)
National Aeronautics and Space Administration	3,084	2,506	2,473	3,220	2,386	2,421
National Science Foundation	975	1,060	1,240	1,014	1,002	1,137
Agriculture	798	850	849	808	839	848
Transportation	309	393	519	349	376	451

Commerce	290	312	227	285	315	249
Environmental Protection Agency	335	241	208	336	295	250
Nuclear Regulatory Commission	221	210	200	209	210	200
Veterans Administration	140	165	163	138	157	156
Agency for International Development	165	152	161	179	200	152
All other [1]	388	391	418	426	425	433
Total	**36,354**	**38,860**	**45,796**	**34,509**	**37,735**	**42,741**

[1] Includes the Departments of Education, Justice, Labor, Housing and Urban Development and Treasury, the Tennessee Valley Authority, the Smithsonian Institution, the Corps of Engineers, and the Federal Emergency Management Agency.

This increase will result in a "real" growth in the Government-wide support of basic research of more than 4% above 1983.

For agencies primarily supporting basic reasearch in the physical and engineering sciences, particularly DOD, NASA, NSF, and including the energy-related programs currently under DOE, the increase in 1984 will be 15% over 1983.

Support for basic research in the life sciences, particularly in NIH, has been growing significantly in recent years. The Administration is seeking, through emphasis on the physical and engineering sciences in the 1984 budget, to balance Federal support of basic research across all major disciplines.

Enhanced support of basic research will further strengthen the scientific capability of the Nation's universities whose researchers receive about half of the total Federal obligations for basic research and conduct about half of all basic research performed in the Nation.

Table K-3 summarizes Federal support for the conduct of basic research by agency.

[1] Amounts reported in this table are included in totals for conduct of R&D.
[2] Includes mathematics and computer sciences.
[3] Includes the Corps of Engineers, the Federal Emergency Management Agency, the Tennessee Valley Authority, and the Department of Transportation.
[4] Includes psychology and social sciences.
[5] Includes the Departments of Labor, Justice, and Treasury, and the Agency for International Development.

R&D FACILITIES

Excellence in research and development requires the availability of modern facilities and equipment. Additional funding for research equipment and instrumentation is included in support for the conduct of R&D including basic research. Funds identified separately by Federal departments and agencies for R&D facilities are summarized in Table K–4.

Obligations for R&D facilities, which include primarily construction or renovation of general purpose laboratories and research support facilities, would decrease by $54 million, to $1,195 million in 1984.

Trends in the funding of R&D facilities generally reflect program directions in agency support for the conduct of R&D as described below.

Table K-4. RESEARCH AND DEVELOPMENT FACILITIES BY MAJOR DEPARTMENTS AND AGENCIES

Part II. Agency R&D Programs

Presented below are summaries of the R&D activities of the 13 agencies whose R&D obligations individually exceed $150 million.

DEPARTMENT OF DEFENSE

The Defense R&D program is oriented toward the development of strategic and tactical weapons and supporting systems to provide for the Nation's defense. DOD obligations for the conduct of R&D in 1984 would total $29.9 billion, an increase of $6.7 billion over 1983. Within the total, funding for basic research would increase by $98 million to $867 million in 1984. R&D facilities funding would total $438 million, up from $323 million in 1983. Major R&D efforts by DOD mission category in 1984 include:

Technology Base and Advanced Technology Development.—The purpose of these programs is to investigate promising new technologies and to avoid technological surprise by potential adversaries. The Very High Speed Integrated Circuits program will continue to push for further miniaturization of microelectronic devices. Increased attention also will be paid to human factors in the Defense mission. Protection against chemical agents, aids for use in training of personnel and exploration of the relation between man and machine will be stressed. Other areas of focus include information processing, materials research, fault-resistant electronics and advanced computer languages.

Strategic Programs.—In addition to the Peacekeeper and Trident II efforts, continued emphasis will be given to ballistic missile defense, an advanced technology bomber and an anti-satellite system. The communications and control systems that are needed for these and existing systems will also receive increased emphasis.

Tactical Programs.—Systems are under development that will improve the capability of U.S. general purpose and theater nuclear forces, and allow the rapid deployment of those forces wherever the vital interests of the U.S. are threatened.

- The Army is continuing work on upgrades to the M-1 tank and Bradley Fighting Vehicle System and is increasing its efforts on remotely piloted vehicles and some areas of air defense.
- The Air Force is developing a deep strike interdiction version of an existing fighter aircraft, a more reliable fighter engine, an air-to-air missile and a new trainer aircraft for undergraduate pilot training.
- The Navy is developing a lightweight anti-submarine torpedo, a new longer range anti-submarine missile and a new destroyer. Upgrades to current subsystems to improve detection, tracking and targeting will also increase the capability of major systems now in production.

Intelligence and Communications, Program Management and Support.—R&D on intelligence and communication systems will focus on communication satellites, on radios that will work in the electronic noise of the battlefield, and on surveillance radars. Work will also continue on the use of technology to reduce manufacturing costs and to extend the life and capability of existing defense systems.

Table K-5. **DEPARTMENT OF DEFENSE—MILITARY RESEARCH AND DEVELOPMENT**

(In millions of dollars)

Type of activity	1982 actual	1983 estimate	1984 estimate
OBLIGATIONS

Conduct of R&D	18,201	21,847	26,844
R&D facilities	232	289	349
Total outlays	**18,432**	**22,136**	**27,194**

NATO Cooperation.—Cooperation in research and development and joint production of new weapon systems will be pursued to make the best use of Alliance resources. Funding for these activities is not identified separately in Table K-5 but is included in the other categories listed in that table.

Table K-5 provides the details of the Department of Defense military R&D funding.

NATIONAL AERONAUTICS AND SPACE ADMINISTRATION

Through the programs of NASA, the Federal Government develops and operates the Shuttle based Space Transportation System and makes investments in R&D that yield other new space technologies to improve the national security and the long term scientific and technological strength of the Nation. NASA programs also provide new knowledge about the Earth, the solar system, and the universe.

Now that the Space Shuttle is in its operational phase, it is no longer appropriate to classify all of NASA programs as R&D. Therefore, the amounts shown for 1982, 1983, and 1984 for NASA R&D exclude funding for Shuttle production and operation, tracking and data acquisition activities, and related institutional support.

In 1984, R&D obligations for the agency will decrease slightly due to spending patterns on previously initiated projects, although new obligational authority for R&D activities is projected to increase by $44 million. Basic research obligations by NASA in 1984 would amount to $682 million, an increase of $77 million over 1983. Obligations for construction of R&D facilities in 1984 would total $156 million.

Space Transportation.—With the initiation of Space Shuttle operations in November 1982, the major R&D phase of the Shuttle program has been concluded. A fully operational and cost effective Shuttle is essential to exploit space effectively and to help maintain U.S. leadership in space throughout this century.

Space Transportation R&D activities provided by the 1984 budget include Shuttle modifications and improvements and continued development of two versions of the Centaur upper stage—a new high energy upper stage for use with the Shuttle. Also included will be a tethered satellite program to extend the use of the Shuttle to conduct scientific experiments in the boundary region between space and the Earth's upper atmosphere. The tethered satellite will be an international cooperative program with the Italian government.

Space Science.—In this area, spacecraft in flight are conducting deep space astronomical observations from Earth orbit or exploring the solar system.

- The High Energy Astronomy Observatory (HEAO), launched in 1979, will continue operations and data analysis activities.
- Two Voyager spacecraft, launched in 1977, have successfully encountered Jupiter and Saturn, and Voyager 2 will continue on its way to Uranus for an encounter in 1986.
- The flight of several other smaller scientific satellites (e.g., International Ultraviolet Explorer) will be continued.

The 1984 budget supports continuation of the flight of these satellites in space and the analysis of scientific data sent back to Earth. It also provides for the retrieval and repair in orbit of the partially disabled Solar Maximum Mission Satellite.

The proposed budget continues development of major flight projects to be launched in the future.

- The Space Telescope is planned for launch in 1985 and will serve as a major astronomy facility for a 15- to 20-year period.
- The Gamma Ray Observatory is planned for launch in 1988 and will enhance basic research in high energy astrophysics, providing new knowledge about objects in deep space.
- Spacelab astronomy experiments, designed for repeated use, will be conducted on the Shuttle to improve our understanding of the Sun and the universe.
- Work is continuing on the Galileo mission to Jupiter; the spacecraft is composed of two segments—an orbiter and a probe to enter the upper atmosphere of Jupiter. The Galileo orbiter and probe will be launched in 1986 and will arrive at Jupiter in 1988 to carry out long-term studies of the planet, its satellites, and its magnetosphere.

In 1984, funds are also proposed to initiate the Venus Radar mapper project, for a 1988 launch, to map the planet. A new Explorer class project for research in ultraviolet astronomy will also be initiated, recognizing the potential of lower cost missions to conduct important science experiments in space.

Space and Terrestrial Applications.—The 1984 budget continues to support research that could lead to the broad application of space technology to national needs. The 1984 budget proposes continued funding for space-related research activities to:

- Improve understanding of Earth resources, climate, weather, and pollution;
- Advance knowledge in materials science and materials processing through low gravity experiments in space;
- Extend the capability for satellite communications to higher frequencies than those employed with current satellites;

The 1984 budget reduction for Space and Terrestrial Applications reflects decreasing obligations in two major projects that are nearing completion, Landsat and the Earth Radiation Budget Experiment (ERBE). However, the budget also includes increasing obligations for an Advanced Communications Technology Satellite (ACTS), while funding for other continuing programs will be maintained at about the same level as in 1983.

Landsat D, the fourth in the series of experimental Earth observing satellites, was launched successfully in July 1982 and is performing satisfactorily. A follow-on satellite will be completed in 1984, ready to succeed Landsat D when needed. Space remote-sensing technology, such as that employed by Landsat D, has the potential to improve our ability to manage critical Earth resources.

The ERBE satellite will be launched by the Shuttle in 1984. The program is designed to provide global measurements of the level of solar and cosmic radiation absorbed by the Earth and also map levels of ozone and other aerosols in the stratosphere. Such observation will help improve our understanding of the factors that determine the Earth's climate.

TABLE K-6. **NATIONAL AERONAUTICS AND SPACE ADMINISTRATION—RESEARCH AND DEVELOPMENT**

(In millions of dollars)

Type of activity	1982 actual	1983 estimate	1984 estimate
OBLIGATIONS			
Conduct of R&D:			
Space transportation systems	890	117	183
Space science	582	752	779
Space and terrestrial applications	319	398	289
Aeronautical research and technology	258	313	300
Space research and technology	118	131	138
Tracking and data acquisition	12	8	22
Research and program management	905	787	762
Total conduct of R&D	3,084	2,506	2,473
Total conduct of basic research, included above	(538)	(605)	(682)
R&D facilities	92	160	156
Total obligations	**3,176**	**2,666**	**2,629**
OUTLAYS			
Conduct of R&D	3,220	2,386	2,421
R&D facilities	109	136	129
Total outlays	**3,329**	**2,522**	**2,550**

The development of the ACTS will be a joint venture of government and industry and will provide advanced, higher frequency, satellite communications technology for use later in the decade.

Aeronautical Research and Technology.—The 1984 budget includes funds for a significant enhancement in new obligational

authority for research in fundamental aeronautical disciplines such as fluid and thermal physics, materials and structures, and propulsion. In addition, technology development at the concept, technique or component level would also be enhanced. Planned obligations for aeronautical R&D will decrease slightly in 1984 because of the extraordinary rate of obligations against prior year authority experienced in 1983. New budgetary authority would increase from $280 million in 1983 to $300 million in 1984.

Funds are included for initiating in 1984, the development of a numerical aerodynamic simulation capability which will further the state-of-the-art of aerodynamic research and design and will also be an important tool for research in areas such as climate modeling and computational chemistry.

The 1984 budget also provides for research and technology development related to the use of composite materials in large aircraft structures. These lightweight materials would result in longer-range and more efficient military and civil aircraft.

Agency-wide support activities.—Obligations for agency-wide support activities would remain at about the 1983 level. These programs include primarily NASA civil service and administrative costs supporting R&D activities, construction and maintenance of the agency's R&D facilities, and R&D addressing fundamental space technology problems and opportunities common to a wide spectrum of space programs.

Table K–6 provides the details of NASA's R&D funding.

ENERGY RELATED ACTIVITIES

Energy related R&D, currently supported by the Department of Energy, covers a broad range of activities: a ***National Defense Program*** related to the development and testing of nuclear weapons: a ***General Science Program*** of basic research in high energy physics and nuclear sciences; and an ***Energy Program*** focused on long-term R&D. Table K–7 provides summary information on the funding of these programs.

Obligations for the conduct of energy related R&D (including facilities) are estimated to total $5.2 billion in 1984, a decrease of $117 million from 1983. Obligations in 1984 for R&D facilities, including the construction or upgrading of laboratories and other research support facilities, will amount to $501 million.

Obligations for the conduct of basic research, included in the total for the conduct of R&D, are estimated to be slightly over $1 billion in 1984. This represents an increase of $160 million, or more than 18% over the 1983 level. Within the basic research total, $82 million would be provided to initiate a number of major new projects in both the Energy Program and the General Science Pro-

gram, that will significantly improve the Nation's capacity for basic research at the frontiers of science. These include:

- initiation of a national advanced materials research center at the Lawrence Berkeley Laboratory to improve the linkages among academic, national laboratory, and industry scientists for the future advancement of high technology industries;
- expansion of the National Synchrotron Light Source at Brookhaven National Laboratory to meet the growing need of industry, national laboratories, and universities for this research tool;
- building on a rapid time scale, a linear colliding beam accelerator at the Stanford Linear Accelerator Center to demonstrate the feasibility of new techniques for very high energy electron-positron collisions;
- upgrading of on-campus Van de Graaff accelerators at the University of Washington and Yale University to maintain the performance capabilities of two essential components of the university based nuclear physics research program; and
- a $6 million university instrumentation procurement program to provide large state-of-the-art equipment used in energy-related research areas.

Highlights of the Energy related R&D activities by major programs are provided below:

The ***National Defense Program*** primarily supports the continued development and testing of nuclear weapons. It also supports the development of improved technologies for monitoring nuclear weapons treaties and of improved methods for safeguarding nuclear materials. In addition R&D efforts will continue in developing methods for the safe storage and disposal of radioactive wastes resulting from weapons production, and research on improved propulsion reactors for naval vessels. Obligations for the National Defense Program for the conduct of R&D will increase from $1.7 billion in 1983 to $1.9 billion in 1984. Funds for R&D facilities in 1984 include construction of the Waste Isolation Plant (WIPP) in New Mexico for R&D on disposal of nuclear waste. Conduct of R&D increases provide funds for staff additions to strengthen the national weapons laboratories, for increased weapons tests, and for increased research in the basic physics of nuclear weapons.

The ***General Science Program*** supports research in high energy and nuclear physics. An increase of $90 million, to $643 million in 1984, for the conduct of basic research will continue support for advanced accelerator concepts as well as for theoretical efforts to understand the basic constituents of matter and energy and the forces that govern their interaction. Because of the exceptional research opportunities in high energy physics and the demonstrated excellence of the U.S. program, the Administration is committed

to maintaining a strong national effort in this field. The 1984 budget request would provide for (a) increased utilization of existing accelerator facilities, (b) operation of the newly completed (1983) Energy Saver Superconducting Synchroton at Fermilab in the 500–1,000 GeV energy range, and (c) continuation of the construction at Fermilab of the Tevatron I and II projects which will provide increased proton-fixed target and proton-antiproton colliding beam capabilities. Funds will also be provided for upgrading accelerators at Yale University and the University of Washington and for initiation of the Stanford Linear Collider (SLC).

The ***Energy Program*** is focused in 1984 on long-term R&D to complement industry investments in new or improved energy technologies. It supports basic and generic research to enhance the scientific base for future advances in these technologies and continues support for the development of selected technologies of a high risk but potentially high payoff nature, such as magnetic fusion, where significant private investment is unlikely. In addition, the Energy Program includes research on the environmental and human health effects of energy production technologies. Energy Program obligations for the conduct of R&D would decrease from $2.4 billion in 1983 to $2.2 billion in 1984, largely reflecting net savings from proposed reductions in non-nuclear technology development and demonstration activities. Obligations for R&D facilities in this area would be $152 million, a reduction of $84 million, paralleling the reduction in the conduct of R&D.

In the *basic energy sciences,* funding for the conduct of R&D and related facilities will increase by $67 million to $350 million in 1984 for research in such fields as nuclear science, chemistry, engineering, materials science, mathematics, biology, and geoscience. This program provides the fundamental scientific and technical base for future advances in technology development. In addition, it provides support for the operation of several unique national facilities such as the National Synchrotron Light Source (NSLS) at the Brookhaven National Laboratory, the High Voltage Electron Microscope at Lawrence Berkeley Laboratory (LBL), and the Electromagnetic Isotope Separation Plant (calutrons) at Oak Ridge National Laboratory. In 1984 a national materials research center at LBL and an upgrade of the NSLS facility will be initiated.

The 1984 budget will continue the redirection of the non-nuclear R&D programs to limit federal support to long-term generic research and place greater reliance on the private sector for support of nearer-term technology development. Obligations for the conduct of R&D in the *fossil, solar* and *conservation* programs are expected to be $302 million in 1984, a decrease of $405 million from 1983.

Funding for the conduct of *fossil* related R&D and associated facilities would be $138 million in 1984, a decrease of $234 million.

The 1984 budget is focused on research to strengthen the technical base for future fossil technology development. Support would continue to be provided in such areas as the chemistry of coal conversion, environmental controls, combustion research, and the understanding of the behavior of oil and gas reservoirs.

Research in support of *solar* energy, proposed at a level of $87 million, will emphasize materials development for a variety of applications and continue to support research in the areas of solar thermal, photovoltaics, biomass, and wind conversion. In 1983, work on the international SOLERAS agreement will be completed. Research to foster energy *conservation* will be focused on improved understanding of energy losses in building systems, research on alternative heat engines, and development of advanced technologies for electrical systems and energy storage. Technology demonstrations in industrial, transportation, and buildings and community systems conservation will be scaled down in 1984. Conduct of R&D for energy *conservation* in 1984 would be $84 million.

The 1984 budget provides for a broad program of research in fission and fusion energy sources R&D. In the *magnetic fusion* program, funding of $467 million for the conduct of R&D and associated facilities would enable the continuation of investigations, at about the 1983 program level, of key physics issues involved with confined plasmas and further research on superconducting magnets, high power radiofrequency electronics, advanced materials development, and mathematical computer modeling needed for fusion technology development.

Within the fission effort the *breeder reactor* program will be funded at $603 million in 1984, maintaining a priority for the design and construction of the Clinch River Breeder Reactor (CRBR). In addition, long-range research will continue in support of breeder technology. Total funding for the conduct of breeder R&D will increase by $62 million over 1983. Other nuclear fission research areas such as *nuclear fuel cycle, converter reactors systems, and advanced nuclear systems* are funded for conduct of R&D and associated facilities at a level of $129 million for 1984.

Additional funds are proposed for nuclear safety and *commercial nuclear waste* management research. For example, in cooperation with the Nuclear Regulatory Commission, technical investigations associated with the disabled Three Mile Island nuclear power reactor will be supported. The fission R&D program will also seek to resolve technical issues associated with the construction of a permanent repository for nuclear waste. Obligations for these activities in 1984 will total $69 million.

Finally, the Energy Program supports R&D to determine the biological and environmental effects of energy production and use. The *biological and environmental research* R&D emphasizes the

health effects of radiation, the use of radiation in medical diagnosis and therapy, and generic biological research related to radiation and other cellular traumas. The level of obligation for such activities will be $158 million in 1984. This effort also supports research to determine the relationship between the CO_2 content of the atmosphere and the earth's climate changes. Funding in 1984 for CO_2 studies will total $12 million.

Table K-7. ENERGY RELATED ACTIVITIES [1]

(In millions of dollars)

Type of activity	1982 actual	1983 estimate	1984 estimate
OBLIGATIONS			
Conduct of R&D:			
National defense program	1,526	1,727	1,905
General science program	500	553	643
Energy program	2,731	2,432	2,165
Total conduct of R&D	4,758	4,712	4,713

Conduct of R&D	4,974	5,012	4,911
R&D facilities	804	623	532
Total outlays	**5,778**	**5,635**	**5,443**

[1] These programs, currently supported by the Department of Energy, will be proposed for reassignment to other Executive departments and agencies.

DEPARTMENT OF HEALTH AND HUMAN SERVICES

The Department of Health and Human Services (HHS) obligations in 1984 for the conduct of R&D would increase by $100 million over the 1983 level to a total of $4.4 billion. Within this total, funding for basic research is estimated to be $2.2 billion. Obligations for R&D facilities would total $29 million in 1984. This represents a decline from the $60 million provided in 1983. The higher level of obligations in 1983 was primarily due to the nonrecurring costs for a single large project—construction of the new research headquarters for the Food and Drug Administration.

Health.—Over 87% of the Department's funds for the conduct of R&D and over 93% of the Department's basic research funds would be obligated by the National Institutes of Health (NIH) for biomedical research to advance the Nation's capabilities for the prevention, diagnosis, and treatment of disease. Several other agencies within the Department—the Alcohol, Drug Abuse, and Mental Health Administration, the Food and Drug Administration, the Centers for Disease Control, the Health Resources and Services

Administration, the Health Care Financing Administration, and the Office of the Assistant Secretary for Health—also support R&D programs in health related research.

The *National Institutes of Health (NIH)* consist of 11 separate Institutes which would obligate $3.8 billion in 1984 for the conduct of R&D, an increase of $71 million above the 1983 level; over one-half or $2.1 billion of NIH's total 1984 R&D budget would support basic research. Among the most significant activities to be supported by NIH are:

- Basic research on cancer chemoprevention including studies of nutritional factors; rehabilitation of patients with chronic obstructive pulmonary disease; prevention of glaucoma; diagnostic imaging, and the biological response to mixtures of chemicals;
- Clinical research where the emphasis is on intervention, including prototype development and refinement of products, techniques, processes, methods, and practices;
- Expansion of cooperative clinical trials on the acquired immunodeficiency syndrome/Kaposi Sarcoma problems; isolated systolic hypertension in the elderly; herpes simplex virus vaccine; and antiviral drugs against neonatal herpes, herpes encephalitis, herpes genitalis; the efficacy of interferon for controlling the frequency and severity of multiple sclerosis; gonococcal vaccines and the prevention of premature labor and the role of folic acid in neural tube defects; and
- Greater emphasis on basic clinical research into the cause, cure, and prevention of diabetes.

The *Alcohol, Drug Abuse and Mental Health Administration (ADAMHA)* conducts studies on the causes, prevention and treatment of alcohol and drug abuse and mental disease and neurological disorders, with emphasis on improving knowledge of effective prevention of these public health problems.

The 1984 budget proposes increases in levels for extramural research programs in biomedical, behaviorial and clinical areas. Obligations for ADAMHA would increase in 1984 to $314 million, an increase of $36 million over 1983.

Specific research areas would address:

- Neurosciences, behavioral sciences, psychopharmacology, and clinical investigations and evaluations of services to the mentally ill, with special emphasis on preventing and diagnosing mental and emotional problems in children;
- Drug abuse among the Nation's youth, including studies on the adverse health hazards of marihuana and cocaine; and
- Causes and consequences of alcohol abuse, particularly among teenagers.

The *Food and Drug Administration (FDA)* supports research relevant to its mission of regulating food, drugs, and biological and radiological products. In 1984, obligations for these activities are estimated at $82 million.

The *Centers for Disease Control (CDC)* supports studies on the epidemiology and control of communicable diseases and on health promotion and disease prevention. In 1984, obligations for these activities are estimated at $75 million.

Other Health Related Agencies within HHS would support research in areas such as how socioeconomic facts affect social security programs and the economy; survey methods and techniques for analysis of health statistics; and the organization, delivery, and financing of health services. This support will be provided through programs of the Health Resources and Services Administration, the Office of the Assistant Secretary for Health and the Health Care Financing Administration.

Human Services.—The Department's obligations for R&D in human services programs in 1984 would be $53 million, $11 million below 1983. The proposed 1984 budget would support a variety of developmental and social service research aimed at improving the Head Start program; the quality of life for the elderly; knowledge of child abuse and neglect; day care systems; family and community support systems and fostering independence for the disabled.

Table K-8 provides the details of the R&D funding of the Department of Health and Human Services.

NATIONAL SCIENCE FOUNDATION

The National Science Foundation (NSF) supports primarily basic research in all scientific disciplines through grants to scientists and engineers in academic institutions. NSF programs serve to advance scientific knowledge. Foundation support is particularly important because it complements the basic research programs of other agencies and assists in balancing Federal support for promising research across all fields of science and engineering.

The 1984 NSF budget includes $1.2 billion in obligations for the conduct of R&D, an increase of $180 million or 17 percent above 1983. This would provide a growth of about 12 percent in addition to cost increases due to inflation. Within this increase, support for the conduct of basic research would increase by about 18 percent. Specifically, the 1984 budget would:

- Provide special emphasis on disciplines such as mathematics, materials science, astronomy, and electrical, computer, and chemical engineering. Research in these disciplines has the potential to make important contributions to the long term

Table K-8. DEPARTMENT OF HEALTH AND HUMAN SERVICES—RESEARCH AND DEVELOPMENT

(In millions of dollars)

Type of activity and organizational units	1982 actual	1983 estimate	1984 estimate
OBLIGATIONS			
Conduct of R&D:			
Health:

Subtotal, Human Services	56	64	53
Total conduct of R&D	3,935	4,316	4,416
Total conduct of basic research, included above	(1,953)	(2,184)	(2,238)
R&D facilities	29	60	29
Total obligations	**3,964**	**4,376**	**4,444**
OUTLAYS			
Conduct of R&D	3,978	4,262	4,339
R&D facilities	38	31	35
Total outlays	**4,015**	**4,292**	**4,374**

competitiveness of the U.S. economy, particularly in high technology dependent industries.

- Provide $180 million in 1984, an increase of 61% over 1983, for upgrading research instrumentation primarily at universities. This sharp increase is included within the support for the conduct of basic research. Along with funds provided for this purpose in other agencies, the increase in the NSF budget would enhance research productivity by helping to alleviate the problem of growing obsolescence of research instrumentation at universities. It would also help ensure that future scientists and engineers are trained in the use of modern research instrumentation and techniques.
- Fund the continuation of the deep sea drilling project to provide scientific geologic information related to the Earth's crust, ocean sediments, geochemistry and paleontology.

In addition, the 1984 budget proposes increased funding in the U.S. Antarctic program for improvement of logistic support. These improvements are critical to the conduct of a safe and effective

research program and to the maintenance of an active and influential U.S presence in Antarctica.

DEPARTMENT OF AGRICULTURE

The Department of Agriculture supports research and development in several disciplines related to agriculture and forestry.

Obligations of the Department for the conduct of research and development are estimated to total $849 million in 1984, a decrease of $1 million from 1983. Of the total, $381 million would support basic research, an increase of $19 million over the 1983 expected obligations of $362 million.

The Department's 1984 budget is highlighted below by major bureau:

The Agricultural Research Service (ARS) would obligate $458 million for research designed to produce new knowledge and technologies required to assure the continuing vitality of the Nation's food and agriculture enterprise. This represents an increase of $12 million over 1983.

In 1984, increased emphasis would be placed on genetic engineering in the plant and animal sciences, human nutrition research, and improved post-harvest technologies. In addition, a new program of post-doctoral fellowships in ARS laboratories would be initiated. Short term applied research and development would continue to receive reduced Federal effort, since such activities are more appropriately financed by the private sector.

The Cooperative State Research Service would obligate $222 million to maintain support of the cooperative program with institutions in 50 States, the District of Columbia, Puerto Rico, Guam, the Virgin Islands, American Samoa and Micronesia engaged in research in agriculture, forestry, veterinary medicine, and the rural home and the community. Also, the budget would continue the competitive grants program in basic research important to increasing the efficiency of food production and improving human nutrition. For the first time, competitive grants for research in the animal sciences would be made.

The Forest Service would obligate $101 million, a decrease of $4 million from 1983, to provide knowledge needed to manage and protect forest and related rangeland resources to gain maximum economic and social benefits from their use. Research would be conducted on: genetics; silviculture and timber management; watershed management; wildlife, range and fish habitats; protection for forest resources from fire and forest pests; surface environment and mining; forest engineering and utilization; and economics of forest commodity production, processing and distribution.

In addition, $68 million would be obligated in other departmental programs for economic research, international cooperation and de-

velopment, transportation of commodities, nutrition information, and statistical reporting.

DEPARTMENT OF COMMERCE

The Department of Commerce has responsibility for ocean science and engineering research, meteorological research and forecasting, and for maintaining measurement standards. The 1984 budget would continue these programs in the National Oceanic and Atmospheric Administration (NOAA), the National Bureau of Standards (NBS), and other areas of the Department.

Obligations for the conduct of R&D by the Department in 1984 are estimated at $227 million, a decrease of $86 million from 1983. This decrease applies largely to relatively nearer term applied research and development, more appropriately the responsibility of the private sector.

National Oceanic and Atmospheric Administration (NOAA).—NOAA would continue R&D programs to develop systems and components for nautical and aeronautical mapping and charting; ocean engineering systems in support of NOAA ocean research and operational programs; better ways to conserve, protect, and manage the Nation's fishery resources; new and improved fishing equipment to protect endangered and/or threatened species; and timely and accurate meteorological, hydrologic, and oceanographic forecasting, detecting and tracking systems for protection of life and property. Obligations for the conduct of R&D by NOAA in 1984 would decrease from $194 million to $135 million. This reduction reflects decreases in applied areas, more appropriately supported by the private sector.

National Bureau of Standards (NBS).—R&D efforts for NBS are aimed at developing and maintaining a system of measurement required to support the Nation's industrial and scientific endeavors.

In 1984, NBS is expected to obligate $78 million for the conduct of R&D. This represents a $16 million decrease from 1983. Funding for the following programs would be terminated or reduced on the grounds that such research can and should be supported by the private sector: fire science and engineering ($6 million), building research ($3 million), ADP standards ($6 million), and recycled oil ($1 million).

Other Commerce R&D Activities.—Funding for smaller research and development programs in the Department of Commerce, which include those in the Bureau of the Census, the Patent and Trademark Office, and the National Telecommunications and Information Administration, would be $14 million in 1984.

38-036 O - 84 - 95

DEPARTMENT OF THE INTERIOR

The R&D activities of the Department of the Interior derive from its broad-ranging responsibilities for management of the Nation's natural resources, including developing energy and mineral resources, restoring and preserving wildlife habitats and wilderness areas, and improving the quality of our water resources.

Obligations for the conduct of R&D for the Department of the Interior for 1984 are estimated at $329 million. This represents a decrease of approximately $44 million from the 1983 level, primarily in applied mining and applied geological research.

Almost 90% of the Department's 1984 funds for the conduct of R&D would be obligated by the Geological Survey ($136 million), Fish and Wildlife Service ($89 million), and Bureau of Mines ($68 million). Highlights of the 1984 research objectives of these and other departmental programs are described below.

The *Geological Survey* undertakes research on the extent, distribution, and character of the Nation's natural resources and on the geologic processes, structures, and hazards that affect the development and use of the land and physical environment. Research priorities in 1984 would include continued development of:

- Accurate appraisals of land and mineral resources;
- New and improved methods of mineral exploration;
- An improved scientific basis for investigation and measurement of water resources; and
- Basic data on geologic principles and processes.

The *Fish and Wildlife Service* supports research performed in the Service's laboratories and field stations, and through cooperative efforts with State fish and game departments. It also provides Federal aid to States for research on restoration of fish and wildlife resources. This research provides basic biological information about species numbers, population dynamics, ecological relationships, and habitat requirements. In 1984, the Service would support research activities concerned with:

- The habitat of waterfowl, migratory birds, mammals and nonmigratory birds;
- Endangered and threatened species status, distribution and threats;
- Impact of broad-scale environmental changes on fish and wildlife populations and habitat; and
- Fish husbandry and aquaculture.

The *Bureau of Mines* conducts basic and applied research across the minerals cycle to improve our understanding of the principles of mining and minerals processing, and to reduce associated health hazards. Reductions are proposed in applied research, particularly in projects of a commercial nature which are more appropriate for the private sector to support. Basic research is proposed to increase

by 22% through reallocations of funds from applied research projects. The 1984 budget reflects an increased emphasis on strategic and critical minerals R&D activities and would stress:

- Long-range, high-risk research in extractive metallurgy technology that may result in new processing methods;
- Development of domestic source substitutes for imported strategic and critical minerals;
- Health-related research on the proper quality and quantity of air flow in underground mines; and
- Longer-term, generic research on fire and explosion prevention, methane and underground control, industrial hazards, post-disaster survival and rescue, explosives, and systems engineering.

Other Departmental Programs would provide for:

- Development of technology to generate additional water supplies by cloud seeding techniques; and
- Development of new materials, planning tools, design and construction techniques to solve problems arising in the development and operation of water resources projects.

DEPARTMENT OF TRANSPORTATION

The Department of Transportation's R&D program is oriented toward providing the information and new technology needed for its own operational (e.g., air traffic control) programs and for regulatory (e.g., automotive and aircraft safety standards) programs. Obligations for the conduct of research and development by the Department are estimated at $519 million for 1984, an increase of $126 million over 1983. The Department's 1984 budget for R&D, with explanations of major changes from 1983, is highlighted below by agency.

The Federal Aviation Administration would obligate $304 million in 1984. The proposed 1984 R&D obligations for FAA represent an increase over 1983 of $161 million. A major portion of this increase occurs in the advanced computer, aviation weather, communications and systems programs. This increase would allow greater emphasis on engineering work to enhance the safety and efficiency of the national air traffic control system, and on emerging technology to improve collision avoidance systems and enroute and terminal air traffic control systems.

The National Highway Traffic Safety Administration would obligate $57 million for motor vehicle research, traffic safety research and demonstrations emphasizing safety belt usage, alcohol counter measures, and for analytical studies. In 1984, a small increase is planned for highway safety research in support of the safety belt program. The National Accident Sampling System which provides

for the collection and analysis of nationally representative accident and injury data would be continued.

The Urban Mass Transportation Administration would obligate $46 million to assist in the development of improved mass transportation systems, equipment and procedures. Emphasis would be placed on research aimed at improving the operation and maintenance of existing transit systems.

The Federal Highway Administration would obligate $49 million to continue research programs in highway planning, design, construction, and maintenance to insure an effective and efficient highway system. Research would also be conducted in identifying, and correcting impediments to highway safety and on improving truck safety.

The Federal Railroad Administration would obligate $17 million to continue highest priority safety research. This would result in more cost-effective safety compliance and enforcement techniques.

The Maritime Administration would obligate $13 million to improve the productivity and competitive posture of the U.S. maritime industries. This level is $4 million below the 1983 budget.

The U.S. Coast Guard would obligate $22 million to support research to maintain and improve search and rescue systems, environmental protection, marine safety, aids to navigation, and the enforcement of laws and treaties, and activities affecting all Coast Guard missions. The proposed 1984 figure represents an increase of $2 million above the 1983 level.

The Research and Special Programs Administration would obligate $5 million to support emergency preparedness and mobilization, hazardous materials and pipeline safety regulatory programs, and long range university research.

The Office of the Secretary would obligate $7 million for broad-based policy research on domestic and international transportation issues of importance to the Nation.

ENVIRONMENTAL PROTECTION AGENCY

The Environmental Protection Agency (EPA) conducts research and development in support of the Agency's regulatory and enforcement missions. For 1984, EPA's R&D program will focus on three major concerns: (1) better linkage of research to the Agency's regulatory priorities; (2) greater attention to quality assurance to improve the reliability of scientific data used in Agency decisions; and (3) restructuring the Agency's long-range basic research program.

Total obligations for EPA's R&D program in 1984 are proposed to be $208 million, a decrease of 14% from 1983. This reduction reflects completion of major research to support regulatory decisions

and reductions for development of pollution control technologies. EPA's major research activities are highlighted below.

The acid rain/energy research program will be increased to understand better the phenomena of acid deposition. Specifically, a comprehensive atmospheric field study will be initiated, dry deposition monitoring will be accelerated, and watershed research studies will be expanded. Research in support of the Limestone Injection Multistage Burner (LIMB) control technology will be continued.

The hazardous waste research program will support efforts on land disposal of hazardous waste, post-closure monitoring of land disposal facilities, screening protocols for hazardous wastes, and research support for permitting hazardous waste disposal facilities.

The Superfund research program will maintain its research efforts at 1983 levels. However, funding will shift from engineering activities to monitoring and environmental effects research which are closely associated with current field work at hazardous waste sites. Funds for this research program are derived from the Hazardous Substance Response Trust Fund which is funded primarily by a tax on oil and chemical industries.

The drinking water research program will strengthen risk assessments, health research, and monitoring for the Drinking Water Program. Resources for groundwater transport and fate research are maintained at 1983 levels. Work will continue on revising the Primary Drinking Water regulations.

The air research program will continue the development of comprehensive health risk assessments for hazardous air pollutants, improve monitoring methods for sampling and analyzing non-criteria organic pollutants and improve air quality dispersion models.

The water quality research program will emphasize research on ocean dumping and water-quality based pollution control requirements. In the municipal wastewater area, research will focus on innovative and alternative wastewater treatment technologies and more efficient sludge management techniques. Industrial wastewater research will be reduced reflecting completion of the effluent guidelines effort and will be refocused to support the waste water permitting program.

The toxic substances research program will increase development of health risk assessment models. Total research funding is slightly lower in 1984 reflecting the completion of a major monitoring study and completion of engineering technical support for the review of chemicals.

The interdisciplinary research program will continue to support the Agency's research centers, long-term research grants, and development of economic benefits methods.

NUCLEAR REGULATORY COMMISSION

The Nuclear Regulatory Commission (NRC) performs research in civil uses of nuclear materials and facilities consistent with public health and safety, environmental quality, and national security. A major share of NRC's effort is devoted to research connected with the use of nuclear energy to generate electric power. Its research objective is to provide safety and analytical methods for assuring the quality of NRC's licensing procedures and regulatory work.

In 1984, NRC's obligations for the conduct of R&D are expected to decrease from $210 to $200 million. This reduction from 1983 is due primarily to the transfer of work at the Loss of Fluid Test Facility (LOFT) to an international consortium. Key areas, such as accident evaluation and mitigation and systems reliability analysis will be strengthened. In addition, reactor safety research, principally on the Clinch River Fast Breeder Reactor, will be continued.

VETERANS ADMINISTRATION

The Veterans Administration (VA) conducts and administers medical, rehabilitation, and health services research. In 1984 this agency would obligate $163 million, for the conduct of R&D.

The VA *intramural biomedical research program* is designed to benefit patients through increased quality and effectiveness of health care delivery. Priorities for 1984 include special research on Agent Orange, alcoholism, aging, and post-traumatic stress.

In *rehabilitation research,* the VA focuses on problems in the field of prosthetics, orthotics, wheelchairs, spinal cord injury and sensory aides for improving the care and rehabilitation of disabled veterans, including amputees, paraplegics and the blind.

The *health services research program* supports projects at VA facilities to improve the effectiveness, economy, and accessibility of health care services. In addition, emphasis will be placed on research relevant to health care delivery to veterans and the services provided to them.

AGENCY FOR INTERNATIONAL DEVELOPMENT

Research and development activities of the Agency for International Development (AID) consist mainly of applied research to solve specific problems associated with basic human needs and social and economic research aimed at improving U.S. and host country understanding of the barriers to development.

Obligations of AID for the conduct of R&D are estimated at $161 million in 1984, an increase of $9 million over 1983.

Programs under AID reflect the administration's recognition of the importance of R&D in addressing the problems faced by the Third World.

The majority of AID's 1984 R&D funds will be devoted to three critical problems: food production, with an emphasis on affecting developing country efforts to overcome the growing food crisis; population growth, emphasizing methods of controlling increasing population growth rates in the developing countries; and energy supply, emphasizing renewable and nonconventional energy sources critical for development to proceed.

OTHER AGENCY PROGRAMS

An additional 9 departments and agencies (listed in table K-2, footnote 1) would obligate an estimated $418 million in 1984, for the conduct of R&D, an increase of $27 million over the 1983 total. Obligations by these agencies amount to less than 1% of all federally funded programs in R&D. The programs of these agencies, like those of other agencies discussed above, are closely related to the agencies' missions.

Among the agencies in this category that expect to increase their obligations for R&D in 1984 are the Smithsonian Institution, Housing and Urban Development, the Federal Emergency Management Agency, the Tennessee Valley Authority, and the Departments of Justice, Labor, and Treasury.

SUPPLEMENTARY INFORMATION

Table K-9 provides information on the long-term trends in Federal funding for the conduct of R&D.

TABLE K–9. TRENDS IN CONDUCT OF R&D

(Obligations in billions of dollars)

Year	Defense [1]	All other	Total
1953	2.8	.3	3.1
1954	2.5	.3	2.9

1984 (estimate)	31.8	[2] 14.0	45.8

[1] Includes military-related R&D programs of the Departments of Defense and Energy.
[2] Excludes NASA funding for shuttle production and operation, tracking and data acquisition activities, and related institutional support.

CHAPTER FOUR

Nondefense Programs

HENRY J. AARON *and associates*

Better the occasional faults of a government that lives in a spirit of charity than the consistent omissions of a government frozen in the ice of its own indifference.

—Franklin Delano Roosevelt

In this present crisis, government is not the solution to our problem; government is the problem.

—Ronald Reagan

THE 1983 budget continues the efforts of President Reagan and his administration to minimize the role of the federal government in all areas other than defense. In particular, the federal government is either being withdrawn from the provision of social services and income maintenance or having its activities curtailed.

President Reagan is forthright in stating the reasons for retrenchment. Services and protections offered by the federal government, in his view, are too numerous and too costly. State and local governments, the president holds, should decide whether or not to provide these services, how much to spend on them, and how to organize their delivery, without federal restrictions or financial support. The twin goals of higher spending for defense and lower tax rates, which the administration takes as immutable, lead inexorably to either intolerable budget deficits or drastically curtailed nondefense expenditures. Furthermore, the furor created by his proposals of May 12, 1981, to cut the long-run cost of retirement, survivors, and disability insurance benefits by 22 percent, has led the president to avoid any mention of reductions

Gary Burtless, Anthony Downs, Louise B. Russell, Gilbert S. Omenn, and David W. Breneman assisted in the preparation of this chapter. In addition, Robert D. Reischauer and Darwin G. Johnson made constructive suggestions on drafts of this chapter, and Diane E. Levin and Julie A. Carr provided research assistance.

Reproduced with permission of the copyright holder from Aaron, Henry J., and others. Nondefense programs. In Setting national priorities: the 1983 budget. Edited by Joseph A. Pechman. Washington, Brookings Institution, 1982. p. 101-150.

in social security in his 1983 budget. Instead, he has established a commission to make recommendations for amending the social security system, but not until after the November elections.

The 1983 budget proposes to cut nondefense spending on programs other than payment of interest to $43 billion below the current services level, lowering total spending in 1983 to $435 billion from the $478 billion that would be necessary to maintain programs at their current services level. These cuts come on top of the $27.1 billion in reductions enacted last year. Both these proposals would reduce the fraction of gross national product devoted to programs other than defense and interest from 15 percent of GNP in 1981 to 12.7 percent in 1983 and to 11.5 percent in 1985. Moreover, the cuts are unevenly divided; the major entitlement programs decline negligibly as a fraction of GNP over this period, while all other nondefense spending plummets (see table 4-1).

The reductions made in 1981 and those proposed this year constitute the Reagan administration's effort to eliminate or to reduce in size most of the social programs enacted during the last fifty years. Social security, medicare and medicaid, higher education assistance, aid to school districts on behalf of disadvantaged

Table 4-1. Nondefense Outlays in Constant 1981 Dollars, Fiscal Years 1981, 1983, and 1985

Billions of dollars unless otherwise specified

children, unemployment insurance, housing assistance, grants for urban and rural development, grants for training and job creation, financial aid to the poor, disabled, and elderly, grants for social services, and legal services for the indigent have all been the target of spending cuts proposed by the Reagan administration last year or this year.

In this chapter we examine some of these cuts in federal spending in the areas of income security, housing, health, and education and training. Because President Reagan's proposals express a coherent view of the appropriate role of the federal government in each area, we also review the rationale for creating the programs. The chapter builds on the tension between the view that these programs fulfill necessary responsibilities of the federal government and the contrary view that they are imposing heavy and unnecessary burdens on the economy.

What Is at Stake

Beginning with the New Deal of Franklin Delano Roosevelt and continuing through successive administrations, both Democratic and Republican, presidents and Congresses have established a series of programs to protect people from economic adversity, to guarantee them minimum quantities of basic goods, and to increase equality of opportunity. To achieve these goals, they created new federal agencies, modified the tax code to promote favored activities, provided grants to state and local governments and private organizations, and issued regulations mandating or prohibiting behavior of various kinds by governments, businesses, and individuals.

In the pursuit of these objectives, the federal government has become an increasingly visible, intrusive, and costly element in the economic and social life of the United States (see table 4-2). Spending has grown; income and payroll taxes have risen (though corporation income tax rates have declined). Federal employment has increased, but less rapidly than the civilian work force. A complex web of economic and regulatory relationships has formed, linking the federal government with subsidiary governments and with private businesses and organizations.

For most of the half-century during which the federal role was

growing, the economy was expanding, first after the low point of the Great Depression, then during the boom of World War II, and finally during the great postwar expansion that, punctuated by brief recessions, lasted until the early 1970s. Beginning in the late 1960s, however, inflation became progressively more serious, and since 1974 the rate of growth of productivity has been negligible, about 1 percent a year. The administration maintains that reducing the size, cost, and influence of government is a necessary precondition for bringing down inflation and restoring economic growth. Others believe that the economic role of the federal government was an important factor in assuring three decades of growth and price stability unprecedented in modern U.S. history.

The division between those who support an active role for the federal government in dealing with domestic social problems and those who feel that government usually creates more problems than it solves rests on two important trade-offs.

The first trade-off is between equality and efficiency. Most nondefense expenditures, other than those for interest on the national debt, occur under programs that provide benefits either to people who experience certain income-threatening events, such as reaching retirement age, becoming disabled, or losing a job, or to people who are judged needy. These programs help the elderly or the disabled to retire. They relieve workers of some of the

economic consequences of unemployment. And they provide the poor with income or with minimum quantities of certain basic commodities. The fraction of the population with money income below the poverty threshold dropped from 22 percent in 1960 to 13 percent in 1980, although there has been little decline since 1968 and the number of poor rose by 3.2 million last year. If in-kind benefits, which have risen faster than money income, are included, as few as 6 percent of the population may be below the official poverty threshold.[1] Also, the taxes levied to pay for these programs are somewhat progressive.[2]

The rationale for such programs is the common observation that many people do not or cannot plan adequately for economic adversity and that the outcomes of the marketplace are sometimes unjust because, in the words of Arthur Okun, they "allow the big winners to feed their pets better than the losers can feed their children."[3] Moreover, there is the plain aversion of many people to indigence, not only for themselves, but also for others. These programs do not seek to equalize incomes so much as to prevent serious declines in income and utter destitution.

Such programs carry a price, however. The most obvious is the taxes imposed to pay for them, which reduce the incomes that taxpayers retain for their own consumption and saving. Taxes distort decisions about how much to work and to save and what to invest in. Furthermore, the programs themselves affect behavior. Retirement benefits may be viewed positively as enabling the elderly to retire, or negatively as discouraging some from working who are capable of doing so. Likewise, welfare payments may be viewed as preventing destitution and providing protection against adversity, or as subsidizing sloth and promoting improvidence. Subsidies for medical care increase the access of the poor, the disabled, and the aged to care they could not otherwise afford, but they reduce the sensitivity of beneficiaries to the cost of care

and increase the likelihood of waste.[4] Thus there is a pervasive trade-off between the goal of helping people judged to be needy and that of minimizing inefficiencies by maintaining incentives based on the threat of economic adversity.

A second trade-off exists between providing help to as many people who need it as possible and not providing help to those who don't—in other words, between errors of omission and errors of commission. The lower the income ceiling for food stamp benefits, housing assistance, or welfare benefits, the smaller will be the number of people assisted who in some sense do not deserve help, but the greater will be the chance that some deserving people will be denied it. Strict rules for disability benefits minimize the number of people capable of working who will be awarded benefits, but increase the number of people for whom work is painful or impossible who will be denied benefits. Reducing social security benefits to people who retire before they reach sixty-five will cause some people who can continue working with little inconvenience to do so, but will impoverish many who are unable to work or who cannot find work.

In all such cases the fact that defined rules and regulations are necessary to minimize administrative caprice and that the average official is endowed with average wisdom means mistakes will invariably be made. The task of designing social programs is to arrive at a consensus of need and to decide how many people deserving of help should be denied it in order to minimize error, fraud, and abuse.

Many social programs enacted over the past half-century have been criticized as inefficient by people who embrace their objectives and agree that the federal government should be actively involved in income support, health, housing, and education. For example, student loans have been criticized because they provide unneeded subsidies to wealthy families; housing subsidies have been criticized because they are needlessly costly; health subsidies have been criticized because they provide excessive pay-

4. It is worth noting that both private and public "third party" payment systems produce the same effects. Evidence that third party reimbursement increases the demand for health care and that the effect depends on the proportion of total cost of which patients are relieved is reported in Joseph Newhouse and others, "Some Interim Results from a Controlled Trial of Cost Sharing in Health Insurance," *New England Journal of Medicine* (December 17, 1981), pp. 1501–07.

ments to some providers and insufficient payments to others. The 1983 budget accepts these criticisms. But it uses them primarily to justify budget cuts, not to design better ways of achieving previously accepted goals.

The 1983 budget may be read as a brief for leaving many of the nondefense functions now performed by the federal government to state and local governments or to the private sector. Congressional action on the president's 1983 budget is best understood, therefore, as a referendum on the wisdom of retaining a major federal role in the financing and provision of social services and income support. Acceptance of most of the president's budget amounts to agreement that many services previously assured by federal administration, financing, or regulation should be provided by lower-level governments with highly disparate fiscal capacities,[5] by private groups, or not at all. Rejection of most of his proposed cuts may be interpreted as a collective recommitment of the federal role in assuring social services and income support. The issue whether programs should be redesigned to achieve their objectives more efficiently than existing programs do is not seriously addressed in the 1983 budget. Nor does the budget recognize the inability of states or localities to deal with concentrated problems of poverty, because of their fear that if benefits are higher than average, taxpayers will flee to lower-cost jurisdictions and the poor will move in.

Table 4-3 summarizes the proposed reductions in a representative list of programs that provide income support and social services and that promote urban development. In this table and throughout the text *real outlays* refer to outlays in 1981 dollars.[6] Some programs are eliminated or cut to a small fraction of their former size, notably public service employment, other training and employment programs, and legal services for the poor. Others are scaled back by 20 to 40 percent, but the basic structure of

5. The Advisory Commission on Intergovernmental Relations compiles an index of fiscal capacity showing the ease with which different states can raise a given amount of revenue. The average value of that index for the top five states is 159.2; for the bottom five states it is 76.4. ACIR, *Tax Capacity of the Fifty States: Methodology and Estimates*, report M-134 (Government Printing Office, 1982), pp. 20–21.

6. The deflators used were derived from *Budget of the United States Government, Fiscal Year 1983*, p. 9–61. When applicable, the deflator for payments for individuals was used; in all other cases (unless otherwise specified), the deflator for "all other" nondefense expenditures was used.

c. Less than $50 million.

d. The net reduction in units represents the balance of 121,000 units authorized for assistance in 1983, less 157,000 cancelations of units authorized in previous years.

many of these programs is transformed, and further cuts are promised. In this second category are elementary, secondary, and vocational education, higher education assistance, food stamps and other nutrition programs, aid to families with dependent children, energy assistance, social services block grants, and community development and urban development block grants. Because many of these programs are scheduled to be turned over to states or to be consolidated into block grants, over the spending of which the federal government would exercise few controls, the budget says little about structural reforms to improve their efficiency.

A third category of programs, including medicare, medicaid, supplemental security income, social security cash benefits, and unemployment insurance, are all retained by the federal government but cut in size, either by actions taken in 1981 or by the 1983 budget. The reductions shown in table 4-3 represent the down payments on future reductions that will flow ineluctably from actions already taken, that are sought by the 1983 budget, or that the administration has clearly indicated it intends to seek.

Income Security

The federal government took up the task of supporting the incomes of needy and dependent people in 1935, when Congress passed the Social Security Act. That law set in place unemployment insurance, retirement and survivors insurance, and aid to families with dependent children (AFDC). Later Congresses initiated housing assistance, disability insurance, food subsidies, and energy assistance. With the notable exception of AFDC, real federal expenditures under each of these programs rose during the 1970s. Now they have all been cut or are the subject of cuts proposed in the 1983 budget. Moreover, the president's proposal that the states assume full responsibility for AFDC and food stamps in exchange for federal assumption of responsibility for medicaid would remove the federal government from involvement with income-tested cash assistance to the nonaged poor.[7]

Aid to Families with Dependent Children

AFDC provides cash assistance to low-income families—usually single-parent families—with dependent children present. The

7. See chapter 5 for an examination of this proposed swap.

states administer AFDC (99.5 percent of the people involved in its administration are state employees) and set benefit levels, but the federal government shares 50 to 77 percent of the total cost of the program. Because states have failed to raise AFDC grants in line with inflation, average benefits for a family of four have fallen 28 percent in real terms since 1972.

In his 1983 budget President Reagan proposes to reduce real federal outlays on AFDC and related programs from $8.5 billion in 1981 to $5.9 billion in 1983, a 31 percent reduction. Of this reduction, $1.3 billion was enacted last year. Proposed changes in the definition of family needs and available family income account for most of the 1983 savings. Family units in larger households will have their basic benefits reduced. Families receiving low-income energy assistance will have this assistance counted in determining available income, so that their AFDC grants will be reduced. The president proposes to require state "workfare" programs, under which recipients of cash assistance would have to work at specially created jobs in order to receive assistance. He is also asking Congress to provide new incentives for states and localities to enforce child support laws, thus reducing the dependence of children on public support. The savings from these proposals are estimated to be $1.3 billion in 1983.

The administration also wants to consolidate and cut federal grants for administering AFDC, food stamps, and medicaid. The 1983 budget proposes not only to reduce grants for administration, but also to reduce and eventually to eliminate any federal sharing in the cost of payments erroneously made. But no penalties will be imposed on states for denial of benefits to people who turn out to have been eligible. Thus the budget unmistakably conveys the message that the administration will not tolerate unjust benefit awards, but is not concerned about unjust denials.

The proposed administrative consolidation of AFDC and food stamps makes sense, but it would bring few substantive changes, because these two programs cover overlapping populations and are already administered by the same state and local agencies. The conversion of the federal grant for administrative expenses from a matching grant to a block grant will undoubtedly induce states to economize on administrative costs, probably to the disadvantage of beneficiaries.

Starting in 1984, the president proposes to turn over to the

states all responsibility for financing and administering AFDC and food stamps. The resulting change in the method of financing these programs would drastically alter the incentives facing state legislatures and governors. At present, states pay on average 46 percent of each additional dollar of AFDC benefits and none of the cost of food stamp benefits. Thus the federal support of the two programs offsets the widely stated fear that providing benefits for the needy at the state or local level will drive up local taxes and drive away business and the affluent. This fear would grow under the administration's plan to give states or localities full financial responsibility for all aid to the poor, and would probably lead to continued and accelerated reductions in that aid.

The changes in AFDC proposed for 1983 (before the program is handed over to the states) continue a pattern established with the president's proposals for 1982. The structure of the program remains unchanged, but proposed technical changes would disqualify some families—especially those with a prime-age potential worker—and reduce the benefits of many more. The reforms enacted last year hit families that have a wage earner especially hard. Until 1981, benefits were reduced by 67 cents for each dollar of earnings in excess of work-related expenses and a $30 a month disregard. As a result of legislation enacted last year, benefits after four months are reduced by a dollar for every dollar of earnings, a 100 percent tax. Also, allowable work-related expenses used in computing net income are sharply reduced. These and other changes add to the restrictiveness of federal welfare regulations, limiting local administrative control of the program and increasing the burden of management.

Supplemental Security Income

Supplemental security income (SSI) is a federally financed cash assistance program for the low-income elderly, disabled, and blind. Some states supplement federal benefits. If no changes are made in the program, 1983 federal outlays on SSI are expected to be $9.2 billion, up 15 percent from 1982. This rise is due both to the indexing of basic benefits and to the quirk that thirteen rather than twelve monthly SSI payments will be made in 1983.[8]

8. Because the first day of fiscal 1984 falls on a weekend, the SSI payment otherwise due on that day will be made in fiscal 1983.

As in the AFDC program, the president proposes technical changes in the payment formula and eligibility definitions that would reduce 1983 expenditures by $300 million, or about 3 percent. Many of these changes are minor and will lower the annual payments to beneficiaries by only a few dollars. But the president also proposes to tighten the definition of disability and disqualify about 115,000 people now receiving SSI disability benefits. With this exception, however, the SSI program has escaped the large reductions proposed for other assistance programs.

Food Stamps and Other Nutrition Assistance

Federal spending on food and nutrition assistance rose irregularly, but rapidly, during the 1970s. Real outlays in 1981 were $16.2 billion, or about 88 percent, higher than in 1973. But the rise in per capita real food stamp benefits from 1974 to 1981 was not large enough to offset the decline in real benefits for AFDC families. A family receiving only AFDC and food stamps qualified for about 18 percent less in combined real benefits in 1981 than in 1974. In fact, combined AFDC and food stamp benefits in 1981 for a family of four with no earnings were 4 percent lower in real terms than AFDC benefits alone in 1969, when the food stamp program was not yet nationally available.

In his 1983 budget President Reagan proposes to continue the reduction of food stamp benefits initiated last year. Real spending is projected to decline by 20 percent from its 1981 level. None of the food stamp proposals for 1983 will alter the fundamental nature of the program. All changes are technical and will principally affect families that receive low-income energy assistance or that have a potential wage earner. The president proposes that energy assistance be counted as income in determining food stamp benefits, that earnings disregards be eliminated (effectively raising the tax on earnings), and that the rate at which benefits are reduced as all forms of net family income (including earnings) increase be raised from 30 to 35 percent. The cumulative effect of the latter two changes would be to raise the tax rate on gross earnings in the food stamp program from about 25 to 35 percent and lower the proportion of increased earnings that food stamp recipients will retain. Other reductions would result from eliminating monthly

payments of less than $10 and modifying the benefit-rounding convention to the disadvantage of beneficiaries.[9]

Federal outlays for administrative expenses would be reduced by providing a block grant rather than a matching grant for state and local expenses; and federal reimbursements for benefit overpayments would be phased out over the four years ending in 1986. Both these changes would increase incentives for states and localities to adopt rules that minimize payments to ineligible families, even at the expense of denying payments to those that are eligible. The administration also proposes beginning in 1984 to turn over to state governments all financial responsibility for food stamps.

In addition, the 1983 budget proposes to abolish the special milk and summer feeding programs. The school breakfast, child care feeding, and women, infants, and children programs would be converted from entitlement programs to block grants with reduced budgets. The president expects these changes to save $300 million in 1983. Real federal outlays on nutrition programs other than food stamps would be down 30 percent from 1981.

The proposed changes in federal nutrition assistance programs will affect all classes of beneficiaries—children, prime-age workers and other adults, and the very old. Such changes as eliminating the special milk program and increasing the food stamp tax on earnings will primarily affect families with modest incomes that are at the upper end of the eligible range, and will probably not have serious nutritional consequences. But such changes as turning the nutrition program for pregnant women, new mothers, infants, and children into a block grant and counting energy assistance in the computation of food stamp benefits are likely to reduce significantly the well-being of the most disadvantaged, especially the very young and the very old. Although there is a sound argument for concentrating nutritional assistance on the most disadvantaged, the president's proposals go beyond this objective and reduce assistance to all types of beneficiaries, even those with no resources of their own. Even the "less disadvantaged," whose nutritional assistance will be reduced by these proposals, are far from well-to-do; nine-tenths of the proposed

9. Monthly benefits will be rounded to the next lowest dollar, thus reducing payments by a few dollars a year.

nutritional cuts are focused on food stamps, a program restricted to families with incomes below 130 percent of the poverty line.

Emergency and Energy Assistance

Since 1979 the federal government has provided block grants to states to help low-income families pay for sharply increased fuel bills. This program protects many of the poorest families from some of the loss they suffered when fuel prices rose after the decontrol of energy prices. The promise of such aid diminished political opposition to the decontrol of energy prices and helped secure passage of legislation that improved the efficiency of the allocation of energy. The Reagan administration now proposes to modify and greatly reduce the low-income energy assistance program. The 1983 budget would combine the grant for energy assistance with the grant for emergency assistance, permit states to apply the combined block grant for hardship assistance as they wish, and reduce outlays to $1.3 billion, 30 percent below expenditures in the last two years. A separate requirement would require states to count energy assistance in determining food stamp and AFDC benefits. This requirement would cause AFDC payments to be cut by up to one dollar and food stamps by 35 cents for each dollar of emergency assistance. As a result, the effective reduction in energy assistance for the poor is far larger than the 30 percent cut in the energy assistance budget. As price controls on gas are phased out and natural gas prices rise, real assistance levels will plummet.

The proposal to take energy assistance into account in the computation of food stamps is inconsistent with the original purposes of both programs. Food stamps help low-income families attain minimum nutritional standards; energy assistance reduces financial hardships arising from the recent rises in energy costs. Under the president's proposal, food stamp aid will decline even though there is no real change in the resources families need to purchase a nutritionally adequate diet.

The Cumulative Effect of Welfare Cuts

The 1983 budget proposals extend President Reagan's cuts in aid to the needy. In 1981 the federal government spent on the needy $33.7 billion through the two cash assistance programs—

AFDC and SSI—and two categories of in-kind assistance programs—food stamps and other nutrition assistance, and low-income energy assistance. If all the president's 1983 proposals were enacted, real spending in 1983 would fall to $26.8 billion, with reductions concentrated in AFDC, nutrition programs, and energy assistance.

Outlays on these programs would decline from just over 1.18 percent of GNP in 1981 to 0.78 percent in 1983. Although the proposed swap of medicaid for food stamps and AFDC, examined in chapter 5, makes projections uncertain, the budget projects a further decline to 0.58 percent of GNP in 1985 if President Reagan's proposals are adopted.[10] Although expected improvements in economic conditions account for part of the reduction, it is the cumulative impact of many small changes in payment formulas, all tending to reduce real benefits to low-income families, that accounts for most of the drop. Because there are so many changes, it is hard to identify the groups that lose most. The increased taxes on income—especially wage income—suggests that low-income families with an earner or potential earner would be hardest hit by the proposed changes.

If beneficiaries get less for working than they did in the past, they would seem to have less incentive to work.[11] But the efficiency argument against raising marginal tax rates is weak. Recent evidence supports the commonsense view that a rise in the rate at which benefits are reduced as earnings rise will discourage work by people who continue to receive benefits.[12] But increasing the rate of benefit reduction lowers the number of people who receive benefits and who are exposed to the program's work disincentives. The net effect is likely to be small.

The fundamental issue is fairness. The largest proposed cuts hit programs for the nonelderly, like AFDC and child nutrition, or programs like food stamps and energy assistance that serve all

10. By comparison, expenditures on these programs equalled 1.10 percent of GNP under the last budget prepared by President Ford.

11. Tom Joe, "Profiles of Families in Poverty: Effects of the FY 1983 Budget Proposals on the Poor," working paper (Washington, D.C., Center for the Study of Social Policy, 1982).

12. Robert A. Moffitt, "An Economic Model of Welfare Stigma," working paper, October 1981, p. 27; and Frank S. Levy, "The Labor Supply of Female Heads, or AFDC Work Incentives Don't Work Too Well," *Journal of Human Resources*, vol. 14 (Winter 1979), pp. 76–97.

age groups. Programs principally for the elderly and disabled, like SSI and medicare, receive much smaller reductions. Families with an earner present suffer the sharpest reductions. The injustice that arises when families with a full-time earner have no more income, and possibly even less, than families dependent exclusively on assistance will be exacerbated. The Reagan changes compress the income distribution among the nation's disadvantaged families by narrowing the income gap between low-income families with wage earnings and those without. Simultaneously, they widen the gap between families with low earnings and those with high earnings, because they deprive the former of income supplements to their wages. Whether the resulting changes in the welfare of different groups are regarded as good or bad will obviously depend on a social judgment.

Social Security

In some ways the most remarkable aspect of the 1983 budget is its failure to propose any changes in retirement, survivors, and disability insurance under the social security system. This program accounts for one-third of nondefense expenditures other than interest, provides benefits to 36 million people, and has grown continuously and rapidly. Despite the size of the program and a looming deficit, the 1983 budget is silent on changes in social security.

The reason for such forbearance is clearly political. On May 12, 1981, the administration proposed a long list of cuts in social security benefits that would have reduced expenditures in fiscal 1982 by $2.5 billion and that would have reduced the long-run cost of the system by more than 22 percent. This proposal generated opposition remarkable for its unanimity. The Senate voted 96 to 0 to disassociate itself from one of the major elements of the proposal, the sharp cutback in early retirement benefits effective in less than seven months.[13] The administration rapidly conceded that it would consider other cuts that would save as much as the ones it had put forward, but the proposal continued to provoke intense and angry criticism. On September 24, 1981, the president

13. Harrison Donnelly, "Senate Opposes Social Security Cuts," *Congressional Quarterly* (May 23, 1981), p. 895.

announced in a televised address that he would not press for action on his proposals, but instead would create a commission to study the social security system and its problems and to make recommendations for changes. The commission was instructed to submit its report by December 31, 1982, after the midterm elections.

Dealing with the social security system presents the administration with severe political problems that arise from the structure of the system, the peculiar financial difficulties that it is experiencing, and the powerful political support it enjoys with most voters. Payroll taxes levied on employees and employers flow into three trust funds, from which retirement and survivors benefits, disability benefits, and medicare hospital insurance benefits are paid. The balance of the retirement and survivors insurance trust fund is declining and will soon reach zero if no action is taken, but the two other trust funds have surpluses for the time being. Last year Congress authorized the trustees to shift resources among the three funds through "interfund borrowing." At that time it appeared that this flexibility alone would cover benefit payments until 1985, when a scheduled increase in payroll tax rates would generate increased revenues. The worsening recession has made clear, however, that even if reserves of all three funds are pooled and combined with total payroll tax collections at legislated rates, revenues may not be sufficient to meet all benefits promised under current law beyond 1984.[14] Thus, not later than 1983, Congress will have to take steps either to increase revenues (by raising payroll taxes, permitting the trust funds to borrow from the Treasury, or allocating other taxes to social security) or to cut benefits.

After this problem is dealt with, the cost of cash social security benefits as a percent of taxable wages will not rise for about three decades. In the first decade of the twenty-first century the cost of social security will begin a three-decade-long rise, as children born during World War II and the postwar baby boom retire. The cost of social security as a percent of taxable wages will rise by about 40 percent. Tax increases already legislated will cover some

14. *Summary of the 1982 Annual Reports of the Social Security Boards of Trustees*, p. 10.

of that rise and will be sufficient to cover benefits for the next fifty years, but more revenues will be necessary to meet legislated benefits after about 2030, according to current estimates.[15]

This long-run problem is almost entirely independent of the short-run financing difficulties with which Congress must soon deal. The large deficits in the Reagan budget, despite the draconian cuts in nondefense spending other than social security, have led members of Congress to suggest alternative budget strategies that entail significant immediate cuts in social security.[16]

Congress faces two decisions with respect to social security: whether to take up the issue as part of its deliberations on the 1983 budget or to wait until next year, and whether to address only the immediate financial difficulties or to take on the long-term deficit, as well. In making this decision, members of Congress must take into account the administration's desire, shown by last year's proposals, to make drastic reductions in social security benefits. A decision to make some short-run cuts, such as deferral of part or all of the cost-of-living increase, would solve the short-run financing problems of the system and let Congress duck the long-run question for the time being. A decision to wait until next year to take up the issue, after the commission created by President Reagan makes its recommendations, would heighten pressure on Congress to deal with the long-run financing questions as well.

Housing and Urban Policy

The Reagan administration has assigned most federal urban-related programs low priority and considers them useful offsets for real increases in such other budget categories as defense. The administration is rapidly withdrawing from previous commitments to spend federal money in urban areas (see table 4-4).

The main issue for federal policy toward urban areas is how the federal government can help big cities cope effectively with the

15. The Social Security Act requires the annual presentation of estimates of costs and revenues of the retirement, survivors, and disability insurance systems over the succeeding seventy-five years. Traditionally the actuaries have presented three estimates. In 1981 they presented five. The statements in the text refer to projection IIB, which is based on intermediate assumptions about economic and demographic events.

16. Senator Ernest F. Hollings (Democrat of South Carolina) and Senator Pete V. Domenici (Republican of New Mexico) have each put forward plans under which the annual cost-of-living adjustment in social security would be skipped for one year.

fiscal consequences of heavy concentrations of poor people. Providing such help has long been regarded as a proper federal role because poverty results in part from the operation of the national economy and because big cities contain a disproportionate share of the poor.

Past experience indicates that poverty, unemployment, crime, arson, drug addiction, and related maladies among the unskilled urban poor remain disproportionately high even during periods of high economic growth and low unemployment at the national level. In 1980 the fraction of people in central cities with incomes below the official poverty level was 17.2 percent, higher than the 15.4 percent in nonmetropolitan areas, and more than double the 8.2 percent in all suburbs combined.[17] Moreover, aiding the poor requires some federal involvement. State or local governments cannot effectively alleviate the problems of the poor, because they fear that if they try to tax the nonpoor heavily to aid the poor, many of the nonpoor will move, usually to nearby suburbs where taxes are lower and they command a political majority. Hence only the federal government, with its relatively inescapable tax system, can finance assistance to poorer citizens and the local governments that serve them.

17. Bureau of the Census, *Current Population Reports*, series P-60, no. 127, "Money Income and Poverty Status of Families and Persons in the United States: 1980" (Advance Data) (GPO, 1981), p. 4.

Recognizing these facts, every administration in recent decades has supported programs that extend financial aid to certain areas. The Nixon administration, for example, initiated community development block grants. The Carter administration spent billions of dollars in its first two years on various antirecession programs tilted toward big cities, assisting both their residents and their governments. Examples are local public works grants, comprehensive employment and training programs, and countercyclical revenue sharing. This aid declined in the last two Carter years but remained sizable through fiscal 1981. Big-city governments received over 40 percent of their revenues from transfers directly from the federal government or from states (which in turn received aid from the federal government).

Most of these programs have been condemned as failures by the Reagan administration, with varying degrees of accuracy. But even programs that produced little useful real output transferred income to hundreds of thousands of low-skilled, low-income urban citizens who were having difficulty finding employment in the private economy. Insofar as the Reagan budget recognizes the problems caused by concentrated urban poverty, it proposes mainly to rely on private-sector economic growth and locally raised public-sector revenues.

Community and Regional Development

The budget explicitly identifies community and regional development as areas where federal spending should be reduced, both to ease budgetary strains and to "get out of the way" of the private sector. The budget authority for both the Economic Development Administration and the Appalachian Regional Commission is virtually eliminated in 1983, a saving of $817 million from 1981. Real outlays taper off more gradually, from $961 million in 1981 to $492 million in 1983 and $132 million in 1985. (Other regional economic development commissions were abolished earlier.) These agencies are good candidates for elimination. The actions of both have always been gestures of federal concern, more symbolic than effective in reviving the depressed areas they were supposed to serve.

Real spending on community development block grants and urban development action grants is scheduled to fall by 23 percent

from 1981 to 1983, and by 30 percent from 1981 to 1985. Obligational authority in nominal terms is constant at $3.9 billion a year from 1982 through 1985, after a drop from $4.4 billion in 1981. These grants are an important way of providing public support to city governments and of helping them cope with their disproportionate share of the nation's poor residents. The money can be used for many physical improvements at the discretion of local governments. The budget states that by not giving inflation allowances for discretionary programs, the federal government "will provide a powerful incentive to reduce overhead, waste, and low-priority activities."[18] It seems likely that a 30 percent real cut in four years will reduce "truly productive" activities too.

Although the 1983 budget frowns on urban areas, it smiles on the countryside. Real spending on rural development in 1983 is 27 percent higher than in 1981, though it falls back close to the 1981 level by 1985. As a result, federal spending on rural development rises from 19 percent of combined community development block grant and urban development action grant outlays in 1981 to 31 percent in 1983 and 28 percent in 1985. The budget provides no explanation for this disparity of treatment. Many rural areas have grown rapidly in population and need added community facilities, but the problems faced by urban areas continue to be serious.

Altogether, outlays on community and regional development are scheduled to fall in real terms from $9.4 billion in 1981 to $6.3 billion in 1983 and $5.3 billion in 1985—declines of 33 percent and 44 percent, respectively, from 1981. About $1 billion of this drop results from assuming that no further disasters like the Mount Saint Helens eruption will occur, but the rest consists of genuine cutbacks.

Housing Subsidies

Because expenditures for housing assistance start several years after initial commitments, housing subsidies will continue to increase from 1981 through 1985 despite sharp cuts in the number of units to be added. Outlays on housing assistance in real terms rise from $6.9 billion in 1981 to $7.8 billion in 1983 and 1985 (up 13 percent over 1981). In contrast, nominal budget authority for

18. *Budget of the United States Government, Fiscal Year 1983*, p. M18.

housing assistance plummets from $26.1 billion in 1981 to −$3.9 billion in 1983 and $2.1 billion in 1985.[19]

This drop reflects a major policy decision to end almost all subsidies for newly constructed units and to slash commitments to other housing assistance as well. The Department of Housing and Urban Development (HUD) plans to cancel about half the 700,000 new subsidized units in process or under construction in 1982. After 1983 HUD will authorize construction of only 10,000 new subsidized units a year (exclusively for the handicapped and the elderly), more than 90 percent fewer than the 111,600 new or substantially rehabilitated units authorized in 1981 and than comparable totals in preceding years. Nevertheless, HUD expects the number of subsidized units to rise from about 3.4 million at the end of 1981 to about 3.8 million at the end of 1985. Half this increase of 100,000 units a year will come from completion of units already in progress, the other half from assistance under a revised housing voucher program. Under this program eligible households would be given a certificate whose value would depend on local housing costs and family income. Households could use the voucher to pay for all or part of the cost of any rental housing unit they might select.

The voucher program resembles the section 8 existing rental housing program, under which eligible households receive subsidies based on family income, but only if they reside in specified existing housing units.[20] The voucher program contains three administrative changes designed to improve cost-effectiveness. Payments under the voucher program will depend solely on incomes of assisted households and average area-wide housing costs, not on individual rents. Each household will be free to negotiate its own housing arrangements with no rent ceiling, as long as it occupies a standard unit. And assistance will be provided in five-year, no-increase contracts with households, rather than fifteen-to-forty-year contracts with landlords. Present section 8 existing rental housing contracts will gradually be converted to

19. For housing programs, budget authority is the sum of new budget authority in the current year less rescissions of previous budget authority. The 1983 budget would rescind $3.9 billion more of budget authority from years before 1983 than it would provide in 1983.

20. Section 8 consists of two parts. Under one part, subsidy contracts are tied to the construction of new housing units. Under the other, subsidies are provided to tenants of existing housing units.

this same arrangement. Experience with the Experimental Housing Allowance Program, a multiyear study of housing vouchers, indicates that these improvements will induce recipients to strike improved bargains with their landlords.

About 111,600 households will be authorized to receive aid through such vouchers in 1983. About 60,600 of these households will be shifted from present rent subsidy programs; 30,000 will be housed in units to be rehabilitated under a new program that is to provide grants of up to $5,000 a unit; and 10,000 will be placed in units now owned by HUD.

Assistance to occupants of existing public housing units will also be cut. The fraction of income required for rent will rise from 25 to 30 percent, and the cash value of food stamps will be included in the income used as a base for computing rents. Families in public housing that receive food stamps will experience a rent increase in 1983 averaging 26 percent, though their rents will still be significantly below those available in the private sector.

HUD defends these cuts in federal housing aid on three grounds. First, the administration holds that its economic program will boost the incomes of the poor and reduce their need for housing subsidies. Second, budget cuts, it is argued, must be made somewhere, and housing subsidies are a reasonable target, because the vast majority of Americans—including most poor households—are well housed. Third, creation of new subsidized housing can be ended because the existing inventory, plus new unsubsidized private construction, is sufficient to provide basic shelter for everyone. As HUD points out, "the major housing challenges we now face are how to help the very poor afford decent housing, how to maintain and preserve the existing housing stock, and how to assure equal opportunity and access to housing markets for all households."[21] Thus the key housing problem of the poor is no longer physically inadequate units, but high housing cost. In 1979 the fraction of renters paying 50 percent or more of their incomes for rent was 49 percent among those with incomes under $7,000, and 73 percent among those with incomes under $3,000.[22]

21. Department of Housing and Urban Development, *Summary of the HUD Budget for Fiscal Year 1983* (HUD, 1982), p. H-2.

22. Bureau of the Census, *Current Housing Reports*, series H-150-79, *Annual Housing Survey, 1979*, pt. C: "Financial Characteristics of the Housing Inventory" (GPO, 1981), p. 7.

Does it make sense to curtail financial assistance when high housing expense, rather than physically inadequate housing, is the main housing problem faced by the poor? It is certainly sensible to shift from subsidizing costly new units for the poor to helping them pay rents on existing units. But it does not seem reasonable to cut back on the second kind of assistance too—unless other income assistance to the poor is simultaneously being expanded. But in fact it is being cut.

Furthermore, the administration's increased reliance on the existing housing inventory and unsubsidized new construction to aid the poor coincides with two factors likely to create at least a mild rental housing shortage. First, high interest rates in 1981 and 1982 have depressed new housing construction. Second, housing demand will increase as more people born during the baby boom reach their late twenties and early thirties. Also, because the real cost of homeownership is much higher in the 1980s than in the 1970s, housing demand is likely to shift from owner-occupied housing to rental units. As a result, rents will probably rise faster than consumer prices generally for the first time in twenty years.

For many years the designers of urban policy have been unable to resolve the conflict between providing aid for people, such as income support or social services, and providing aid to places, such as grants for commercial redevelopment or new housing. The Reagan administration has resolved that conflict by seeking major reductions in both.

Urban Transportation

Real federal outlays on ground transportation will fall from $17.1 billion in 1981 to $11.4 billion in 1983 (down 33 percent) and to $9.7 billion in 1985 (down 43 percent from 1981). Specific declines from 1981 to 1983 stated in 1981 dollars are $2.6 billion in railroad subsidies (down 71 percent), $1.8 billion in highway subsidies (down 20 percent), and $1.1 billion in urban mass transit subsidies (down 28 percent). The most important of these reductions for cities is in urban mass transit aid, because federal operating-cost subsidies will be eliminated. In 1981 the federal government paid about 15 percent of the operating costs of all urban public transit systems. The administration proposes to continue some capital subsidies, though not for new fixed-rail systems, which are more costly to build and operate than alter-

native modes of transportation. But it also plans to phase out operating-cost grants over a three-year period. It argues that federal subsidies have let local governments avoid raising fares to cover costs and have perpetuated inefficient forms of service.

Not only are these claims valid, but federal subsidies also contribute to another major inefficiency: high wage settlements by labor unions with power over wage levels and organization of local transit service. Transit drivers are paid as much as $12 an hour, as against $5 an hour for taxi drivers and nothing for the millions of auto commuters who drive themselves. In 1978 over half of all federal spending on urban highways and mass transit went into mass transit, which accounted for only 3 percent of all urban passenger miles traveled.[23]

Withdrawal of federal subsidies for operating costs would create critical problems for many public transit systems. Systems that provide overexpensive service to low-density areas at fares below cost will change to less extensive routes and more diversified services, not confined to those operated by union-wage drivers. Such services could include jitneys, taxis for the elderly and handicapped paid for by vouchers, van pools partly financed by employers, and higher-priced peak-hour buses.[24]

Because mass transit is locally produced and consumed, placing responsibility for both funding and operating it on states and localities appears sensible. Abolition of federal subsidies would force localities to confront the true costs of their present transit services, which are now masked by those subsidies. The transition would be painful in many cases, especially for the New York area, which has 32 percent of all mass transit patronage. But it should improve the efficiency of the transportation system.

Complete abandonment of responsibility for mass transit operations by the federal government raises two important equity issues. One concerns the disparity of resources among different regions. It seems reasonable for each region to pay for its own public services, like mass transit, but such energy-rich states as Oklahoma have abundant taxable resources, while others like

23. This estimate applies to spending in 1975. It was made by Alan Altshuler in *The Urban Transportation System: Politics and Policy Innovation* (MIT Press, 1979), p. 35.

24. For an excellent analysis of the future of urban mass transit, see Milton Pikarsky and Christine M. Johnson, "After the Dust Settles: Transit in Transition," working paper (Chicago, 1981). Pikarsky is at the Illinois Institute of Technology Research Institute, and Johnson is with the Checker Taxicab Company.

38-036 O - 84 - 97

Maine do not. Is it just that the former with lower tax rates can buy much better public services, in general, and mass transit services, in particular, than the latter can?

The second issue arises because mass transit is used disproportionately by people with little income, the aged, and those with disabling handicaps. In the United States public transit is mainly an "inferior good"; that is, as soon as you can afford a car, you stop using the bus. Thus many transit patrons—especially those who travel outside of rush hours—cannot afford private cars, or cannot use them because of handicaps. Forcing transit systems to raise prices would increase the economic burden on these involuntary patrons, many of whom are poor. However, the most deprived could often be provided superior service by alternative systems that do not cover such extensive routes or use such expensive drivers. Examples are taxi service for the handicapped or non-union-driven van service for the elderly. In the case of public mass transit, therefore, the stimulus to greater efficiency caused by withdrawal of federal operating-cost subsidies probably outweighs the negative effects.

Health

Federal health policy has long pursued three objectives that now are in open conflict with one another. The federal government has tried to improve access to medical services of the poor, the aged, and selected groups such as Indians. It has underwritten the largest program of biomedical research in the world, principally through the National Institutes of Health. Finally, it has sought to hold down the costs both of its own programs and of those financed by private expenditures or by state or local governments.

The 1983 budget sustains federal interest in research and emphasizes cost containment, but signals a broad retreat in efforts to improve the access to medical care of groups that cannot afford it.

The Health Budget

Expenditures on health care are among the most rapidly growing in the federal budget because of rising outlays under medicare (see table 4-5). Medicare has covered the aged since it began in

Table 4-5. Outlays for Federal Health Programs in Constant 1981 Dollars, Fiscal Years 1981, 1983, and 1985

1966 and the disabled and those with end-stage kidney disease since 1973. Medicaid, the next largest federal health program, pays for acute and long-term care for recipients of AFDC, for the aged and disabled poor, and, in thirty states, for the "medically indigent," or people with low incomes who are not receiving welfare. To obtain federal matching grants under medicaid, states must offer seven mandatory medical services and cover all persons who are receiving supplemental security income or aid to families with dependent children. But states may cover additional people and offer additional services. The rest of the health budget will have been reduced 11 percent in real terms between 1981 and 1983 if all changes proposed by the president are adopted. These outlays consist of $4 billion on health research, mostly by the National Institutes of Health, $1.5 billion on four new block grants created last year that absorbed many grant programs, and the remainder on a variety of programs that for the most part were significantly cut last year and are slated to be cut again this year.[25]

Under medicare and medicaid the federal government, with some help from the states, has shouldered primary responsibility for financing medical care for groups that have great need for care but often little capacity to pay for it. Both programs have tried to

25. The budget does not include in the health function the large expenditures for health care undertaken by the Defense Department for members of the armed services and their families and by the Veterans Administration or health insurance premiums for federal employees.

bring their beneficiaries into the mainstream of American medical care, paying for almost the same care, in the same institutions, that is available to more affluent Americans.

The results have been impressive. All indicators show that the elderly use hospital and nursing home services far more than they did before medicare. The poor that are covered by medicaid now use about as much medical care as the more affluent. The increased use of medical services may have contributed to the large gains in life expectancy among the elderly since 1965 and to the sharp drop in infant mortality, especially among blacks.[26]

National medical expenditures have also risen dramatically in constant 1980 dollars, from $124 billion, or 6.0 percent of GNP, in 1965, to $247 billion, or 9.4 percent of GNP, in 1980. The main forces behind this growth have been the increased range and power of medical services and the rising income of American consumers, accompanied by spreading third-party coverage, since World War II. The aging of the population has contributed only slightly to past increases in health care expenditures, but it will be more important in the future.

Background on Efforts to Contain Costs

By the early 1970s it was clear that the growth of medical expenditures, both governmental and national, was not a temporary problem, but one with deep and persistent causes. The first efforts to slow the growth of federal expenditures did not alter the basic nature of medicare and medicaid. In 1972 Congress authorized professional standards review organizations, groups of physicians charged with reviewing hospital stays for medicare and medicaid patients and empowered to disallow payment for medically unnecessary services. The same legislation gave medicare administrators the right to limit hospital payments. Individual states began to require hospitals to obtain state approval before undertaking major investments, seeking thereby to eliminate "unnecessary" or duplicative facilities. In 1974 Congress required all states to enact legislation requiring health care providers to obtain a certificate of need for new investments and stated that payments under the Public Health Service Act could be denied if states failed to comply.

26. See Louise B. Russell, "Medical Care," in Joseph A. Pechman, ed., *Setting National Priorities: Agenda for the 1980s* (Brookings Institution, 1980), pp. 178–80.

The Nixon administration imposed wage and price controls on the health industry (from August 1971 to early 1974) as part of the economic stabilization program and left these controls in place for some months after those on the rest of the economy had been lifted. The controls interrupted the rapid growth of health expenditures, which averaged 8.4 percentage points more than the increase in the consumer price index for the five years preceding the freeze. As soon as controls were removed, expenditures shot up and rose an average of 11.1 percentage points a year more than the consumer price index through 1977.

Continued growth in expenditures led Presidents Ford and Carter to propose more fundamental changes. President Ford proposed limits on the rates of increase of reimbursement for hospitals and physicians under medicare. He also proposed billing patients for 10 percent of the costs of hospitalization. In return, coverage of very large bills would have been improved. Congress never considered these proposals seriously, and President Carter withdrew them.

Instead of trying to control the growth of medicare and medicaid alone, President Carter asked Congress to limit the growth of hospital expenditures in general. Such a limit would have reached not only the 75 percent of medicare and almost 40 percent of medicaid expenditures represented by hospital bills, but also private expenditures. Confronted with intense lobbying from the hospital and business sectors, Congress did not enact the Carter proposals, ostensibly because it wanted to see whether the so-called voluntary effort by hospitals to hold down costs would prove effective and obviate the need for federal regulation. The voluntary effort survived as long as the possibility of federal legislation seemed real, and held growth of hospital expenditures to only 3.4 percentage points more than the rise in the consumer price index from 1978 through 1979. Cost containment legislation was defeated definitively in 1979. By 1981 hospital expenditures were rising 8.4 percentage points more than other prices.

As the years of swelling medical expenditures have become decades, it has become clear that fundamental changes are necessary if expenditures are to be controlled. Effective cost control must alter the incentives of patients and providers, either through cost sharing or through some kind of budget limit. Cost sharing forces patients to consider whether the care they seek is worth

what it costs them.[27] Budget caps place a limit on the revenues of hospitals or other providers. Implementing a budget limit would require a considerable amount of regulatory interference, however. How should hospital limits vary with the facilities, case mix, and fixed costs of each hospital? Before increasing reliance on cost sharing, it would be necessary to decide whether payments should depend on the income or other characteristics of patients or providers. If beneficiaries were required to choose among alternative health insurance plans, it would be necessary to decide what protections to give patients, particularly the elderly, who may be too uninformed or bewildered to make sound judgments. These and other questions will have to be addressed in the competition plan that President Reagan has promised to present.

Some people hold out hopes that two other approaches to medical care—consumer education and scientific advances—may reduce costs, but these are at least as likely to raise costs as to lower them. Consumer education may deter people from seeking care for trivial or self-healing illnesses, but there is considerable risk that improved consumer education will increase demand for medical care, and, in any event, consumer education itself is costly. In the long run scientific advances may reduce the cost of health care. But though discovery of the fundamental causes of major life-threatening or disabling diseases may prevent premature deaths, it may also increase the frequency of slow and costly decline and the opportunities for costly medical intervention to improve the quality of life during these declining years.

1983 Budget Proposals

The health proposals in the 1983 budget reflect no unifying theme or philosophy other than the desire to hold down costs. They constitute a mélange of short-term measures to slow the growth of health outlays while the administration completes the design of its competitive strategy to slow the long-run rise in the cost of medical services. Because federal programs focus on

27. Results from a major health insurance study initiated by the Office of Economic Opportunity, continued by the Department of Health, Education, and Welfare (now the Department of Health and Human Services), and managed by the Rand Corporation show that the demand for health care is 14 percent greater when there is no cost sharing than when patients must bear 25 percent of the cost (up to $1,000 or a certain fraction of income, if less). See Joseph P. Newhouse and others, "Some Interim Results," p. 1501.

vulnerable populations, notably the aged, disabled, and poor, the reductions will cut the access of these groups to medical care, thus reversing a trend dominant since medicaid and medicare were enacted in 1965.

Proposed cuts in medicare total $2.5 billion in 1983. The most important would disallow reimbursement for 2 percent of every medicare hospital bill. Hospitals would be paid 98 percent of their incurred costs and would be prohibited from charging the patient the remainder. This proposal would reduce federal spending by an estimated $653 million in 1983. A large part of these costs would reappear as increases in private insurance, as hospitals tried to shift costs to other payers. An additional $306 million would be saved by requiring employers to provide the same insurance for workers aged sixty-five through sixty-nine as they offer to younger workers and by requiring such insurance to pay for care before medicare is billed. At present, private health insurers are usually charged for the medical costs of elderly workers only after medicare has paid for all covered services. Because medical care is more costly for elderly persons than for younger workers, and because most employers pay premiums that cover the actual cost of care for their employees, this provision may deter employment of older workers. The administration has eliminated professional standards review organizations on the ground that they do not save money, yet it claims $362 million in savings from the proposed expansion of utilization review by contractors who process medicare claims. A variety of smaller changes—shifting the update of physician fees from July to October (the next fiscal year), raising the deductible charged for coverage of physician bills to take account of inflation, reducing reimbursement for hospital-based radiologists and pathologists, delaying medicare coverage until the first full month of eligibility, and others—make up for the rest of the proposed $2.5 billion cut.

The administration also seeks to impose medicare payroll taxes on federal employees, most of whom acquire eligibility from nonfederal employment during their working lives. This proposal is a new, but justified, tax for these federal employees, yielding $619 million in 1983.

The list of proposed changes in medicaid is almost as long as the list for medicare, but the effects on access are likely to be

more serious, because medicaid benefits in many states are already far more restrictive than medicare benefits.[28] For example, medicaid in New Hampshire covers only twelve days of hospitalization a year; Tennessee and Kentucky cover fourteen days.[29] A 1975 survey of the Health Care Financing Administration found that medicaid fees were roughly three-quarters of those under medicare. Another survey found that medicaid reimbursements were 40 percent below normal fees.[30] Only half the people living in families with incomes below the official poverty line ($8,450 for a family of four in 1980) are eligible for medicaid.

The most important cuts in medicaid would reduce the federal matching rate for optional services and optional beneficiaries by three percentage points. All states offer some optional services; the most important, intermediate care, accounts for 27 percent of total medicaid expenditures.[31] In addition, the administration proposes to stop matching payments for the medicare part B premiums of those medicaid beneficiaries who are also eligible for medicare. In combination, these cuts would save $803 million in 1983 if adopted.

In addition, the administration would require medicaid patients to pay small sums for physician and hospital services; this cost sharing is projected to save $329 million. Reductions in eligibility for AFDC and SSI welfare payments, increased authority for states to collect nursing home costs from patients' relatives and estates, a cap on administrative costs, and other changes, are expected to bring net savings to almost $1.6 billion, a $2 billion saving for the federal government and a $0.4 billion increase in costs for the states. These proposals follow the administration's attempt last year to place a cap of 5 percent on the allowable annual increase in medicaid expenditures. Bipartisan congres-

28. One very important exception to this statement is the coverage of long-term care or nursing home services, which is far more generous under medicaid than under medicare. In fact, 41 percent of medical expenditures under medicaid in 1981 went for long-term care.

29. National Governors' Association, *Catalogue of State Medicaid Program Changes* (Washington, D.C.: NGA, 1981), pp. I-7–I-10.

31. Intermediate care includes some costly nursing home care for the elderly. But it also permits physicians to discharge patients who are unable to care for themselves from hospitals to less costly nursing home beds.

sional rejection of that proposal last year suggests that the proposed cuts in medicaid will face considerable opposition.[32]

The most striking proposed change in medicaid, announced by President Reagan in the State of the Union Message, calls for federal assumption of full financial responsibility for medicaid in return for full assumption by the states of the costs of food stamps and AFDC. Unfortunately, no detailed plan existed at the time of the speech. It was not clear whether the enormous geographic variations in medicaid would be allowed to persist. The best guess is that some attempt will be made to set national standards, but it is unclear at what level these standards would be set and what protections would be afforded present beneficiaries. It is also unclear whether administration, now almost wholly in the hands of the states, would be federalized and, if so, what protections would be afforded state administrative employees. The Department of Health and Human Services began the task of answering these questions only after the president's speech in which the plan was unveiled.

Block Grants in Health Services

During the 1960s and 1970s successive administrations sought, and Congress enacted, many narrowly targeted grant programs to achieve specific health objectives. Almost as the programs were being created, these same administrations and Congresses recognized that their number bred confusion. As early as 1966 President Johnson sought to consolidate nine formula grants under the Partnership in Health Act. Last year President Reagan requested that twenty-six programs be lumped together in two block grants, one for preventive health and one for health services. The president sought simultaneously to reduce authorizations of these programs from $1.9 billion to $1.4 billion, a 25 percent cut in both preventive health and health services.

Congress gave the president some of what he sought. It created four block grants: in preventive health and health services; in

32. Instead of a cap, Congress merely cut its projections of the growth of medicaid expenditures in the budget resolution. Of greater significance, Congress authorized the negotiation by states of lower charges through restrictions on providers, capitation, and prospectively determined payments, instead of relying on cutbacks in eligibility and benefits. It is too early to know what savings will be achieved.

maternal and child health; in alcohol, drug abuse, and mental health (little changed from previous structure); and in primary care (which simply renamed the existing community health center program). Real expenditure on these programs was reduced by 28 percent. Of greater significance was the complete exclusion from the block grants of ten programs that the president had wanted to include, among which venereal disease control, family planning, and migrant health centers were the most visible and most controversial. But the real outlays for these programs were cut 19 percent. Given the financial difficulties that many states are experiencing, few are likely to find resources to make up for reduced federal spending.

For 1983 the administration again proposes to include in block grants the programs whose separate status Congress protected last year. In particular, the 1983 budget again seeks to fold migrant health and family planning into the primary care block grant. The maternal and child health block grant would absorb the nutrition program for women, infants, and children, now administered by the Department of Agriculture, and $284 million would be cut from the $934 million allocated to the program in 1982.

The Plan to Promote Competition

The administration's long-awaited proposals to promote competition in the medical system are expected later this year. The administration must decide whether to try to promote competition in private insurance, in medicaid and medicare, or in both. Application of the competitive strategy to private insurance raises very different issues from those relating to publicly financed programs.

If the administration decides to tackle private insurance, the legislation is expected to resemble the competition bills submitted in the past by, among others, former congressman David A. Stockman and former senator Richard S. Schweiker. These proposals sought to control the cost of health care by increasing the sensitivity of patients and providers to the costs of the services they seek and provide, primarily by requiring employers to offer several plans to their employees (ideally, one a health maintenance organization [HMO]—an organization of physicians that undertakes to provide or arrange for virtually all the medical care

required by the plan's subscribers in return for a fixed annual payment—and another with substantial cost sharing) and by setting a limit on health insurance premiums that employers may deduct as legitimate business expenses or that employees may exclude from taxable income.[33] These measures are designed to encourage workers to weigh the value of additional health benefits against other consumer goods. An employee who chooses a plan that costs less than the employer's contribution (which would be required to be uniform for each plan) would receive a rebate.

The chief obstacles to applying the competitive strategy to the private sector are political. Few groups involved in the delivery of health care stand to gain from an increase in competition; most, therefore, will fight it. Furthermore, slowing growth in the cost of private insurance has little direct effect on the federal budget.

Applying the competitive strategy to public programs would directly affect the budget and should have considerable political appeal, but it is not clear how to implement the strategy. In principle, the competitive strategy is simple enough: the government would offer beneficiaries vouchers for the purchase of private insurance, rather than automatically reimburse providers for a predetermined list of services. In practice, however, vouchers are an unknown quantity, and a host of questions must be resolved before they can be issued. A decision must be made on the value of the vouchers and on how the value should vary according to the characteristics of the beneficiary. No one knows how much coverage private insurers can offer for a payment equal to the current cost of medicare per enrollee, particularly because private insurers must incur selling costs that medicare is spared, and would be less able or less willing than medicare to bargain for or to impose low rates of hospital reimbursement.[34] If successful, the competitive strategy might offset these disadvantages in the long run; but in the short run costs might well increase, and even

33. Employers now may deduct without limit the cost of health insurance purchased for employees. Individuals are not required to include in adjusted gross income the value of such employer-financed health plans. In addition, individuals may deduct 50 percent of the health insurance premiums they pay, up to $150, and include additional premiums in health expenditures, which may be deducted to the extent that they exceed 3 percent of adjusted gross income.

34. Some estimates put the initial cost of vouchers offering the same benefits as medicare at 130 percent of current per capita medicare expenditures.

long-run success is speculative. Nor does anyone know how to handle nursing home care, which is seldom covered by private insurers but which accounts for 41 percent of the cost of medicaid.

Faced with such vexing problems, the task forces working on the administration's proposals may treat vouchers as experimental and permit enrollees the option of retaining basic medicare coverage. If this course is followed, a competition plan will have little effect on federal outlays; it may even increase them if high-cost patients remain with medicare while low-cost patients accept the voucher and purchase private insurance. Another course of action, reportedly under consideration, would require hospitals to accept payments fixed in advance under medicare (and conceivably under medicaid when it is federalized). Prospective reimbursement, however, is nothing other than a particular form of budget limit, much like those previously proposed by Presidents Ford and Carter.

In summary, the 1983 budget joins a long list of budget documents that have expressed concern over runaway medical costs and have taken only modest steps to curb them. The administration promises a new competitive strategy for dealing with this fundamental problem and attributes large savings to it in 1983 and later years, but the plan has not been worked out. The 1983 budget makes clear, however, that the twin problems of rising medical costs and federal deficits have terminated efforts to equalize access to medical services. Rather, efforts to curb federal health care expenditures are reviving the question whether the poor, the aged, and the disabled are to be assured health care on the same terms as others.

Education

The central question posed by the Reagan administration about education is whether there should continue to be an active federal role at all. Education programs rank high among the federal activities that the administration hopes to return to state and local control. This proposed shift would be accompanied by sharp reductions of federal financial support. Real budget authority for elementary, secondary, higher, and vocational education in 1983 will be 43 percent lower than in 1981 if Congress heeds President

Reagan's budget requests (see table 4-6). The budget projects a further 26 percent cut between 1983 and 1985.

Reductions of this magnitude cannot be construed as simple reforms to eliminate waste, fraud, and abuse. They challenge the assumptions and fundamental purposes that have guided federal policy in education for the last two decades. This year the debate should focus on whether those assumptions and purposes remain valid and important.

Although the history of federal involvement with education begins with the Northwest Ordinance Act of 1787, the rapid growth of federal support for education occurred during the last twenty-five years. The post-sputnik emphasis on improved scientific and technical training gave way during the 1960s and early 1970s to a concern for equality of educational opportunity. For the last decade the main objective of most federal elementary, secondary, and higher education programs has been to increase educational opportunities for those who have lacked them. The largest elementary and secondary programs serving this goal are title I of the Elementary and Secondary Education Act of 1965,[35] which provides extra money for school districts serving low-income, low-achieving youngsters, and the Education for All Handicapped Children Act of 1975, which requires a "free, appropriate education" for all children, regardless of handicap. In 1981 title I provided over $3 billion in compensatory education services for more than 5 million children in 14,000 school districts, and over $1 billion was appropriated to help states and localities

35. Now chapter 1 of the Education Consolidation and Improvement Act of 1981.

meet the costs of educating handicapped children. Other categorical programs, such as Indian education, bilingual education, follow-through, and the Emergency School Aid Act, assisted other needy children.

In higher education, the basic educational opportunity grant program (renamed Pell grants after Senator Claiborne Pell of Rhode Island) was enacted in 1972 to assist students from low-income families pay for college. Pell grants, together with other grant, loan, and work-study programs, contributed over $6 billion to the support of low- and middle-income students in 1981. Social security provided nearly $2 billion to eligible families on behalf of students over eighteen, and the GI Bill contributed more than $1.5 billion in educational benefits to veterans. Enactment of the education amendments of 1980 reaffirmed the federal partnership with state, local, and private agencies in supporting equal educational opportunity for all citizens. It is this commitment that the Reagan administration has cast in doubt.

Elementary and Secondary Education

Table 4-7 presents the budget authority requested for the principal elementary and secondary programs in 1983 and projections for 1985.

The Education Consolidation and Improvement Act of 1981 rewrote the Elementary and Secondary Education Act of 1965 by combining twenty-nine categorical programs into a state education block grant (chapter 2, ECIA). It retained compensatory education as a separate program (chapter 1, ECIA), but relaxed the requirements governing state and local allocation of funds. When added to the actions taken last year, the proposed 1983 cuts would reduce real budget authority for compensatory education by more than 45 percent from 1981 and block grants by 38 percent. This year the administration proposes two further consolidations, one for programs serving the handicapped and the other for vocational and adult education, with increased state and local discretion in the use of funds.

The administration justifies the proposed cuts in budget authority by noting the "overall need for fiscal restraint" and by stating that the cuts "represent lower priorities for Federal funding

c. The Carter administration had estimated budget authority in fiscal 1981 at $7.3 billion. The main differences are in vocational and adult education ($139 million), education for the handicapped ($50 million), and other ($307 million).

than other activities."[36] The administration also claims that increased flexibility in the use of funds at the state and local level will make it possible for the neediest children to be served despite the sizable cut in resources. This assertion may have some validity, but increased efficiency will not offset a 43 percent cut in real resources over two years. Instead, fewer instructional services will be provided to a smaller number of students.

The administration candidly acknowledges that it does not place much value on the expenditure of federal revenues for the purposes served by these programs, preferring instead to turn back these responsibilities to the states. Some states may take up the responsibilities that the Reagan administration proposes to abandon. But the same incentives that discourage states from providing income assistance to the poor will deter states and, especially, municipalities and school districts from fully replacing federal assistance. The decision to accept or to reject the administration's proposals must address the question of the degree to which a just society will permit large differences in educational opportunities for its citizens.

36. Office of Management and Budget, *Major Themes and Additional Budget Details, Fiscal Year 1983*, p. 152.

Equity, however, cannot be the sole criterion for judging the proposed budget cuts. If programs such as title I did not produce gains in educational achievement, then the funds should be cut, and their loss would have little effect on educational opportunity. But a recent comprehensive evaluation of title I found statistically significant gains in achievement by title I students relative to control groups.[37] Educational gains were made in mathematics in all six primary grades and in reading in grades one through three.

The more difficult question is whether the increased achievement of 15 to 20 percent per student in the primary grades is worth the roughly $460 spent per child from title I funds.[38] Until more is known about the subsequent education and employment of students helped by title I, it is not possible to compare benefits with costs. What is clear is that the proposed real cut in title I budget authority of 45 percent between 1981 and 1983 will reduce the number of children receiving compensatory education by approximately 1 million and reduce assistance to those who remain in the program.[39]

Most federal support for handicapped students comes from the state grants authorized by the Education for All Handicapped Children Act, but in 1982 about $360 million also came from compensatory education for state-operated programs (chapter 1, ECIA), from preschool incentive grants, and from other discretionary programs. The administration proposes to consolidate these programs and to provide block grants to the states, which will allow increased flexibility in the use of the funds.[40] The $846 million requested for the consolidated program is roughly half what would be required in 1983 to maintain the federal share at 12

39. The administration estimates that 4.3 million children can be served in fiscal 1983 if states can lower costs per student to $400.

40. The Carter administration early considered a comparable consolidation, but dropped it when political opposition became evident. Constituent groups argued that more federal support for handicapped children would be forthcoming from several programs than from one.

percent of the national average expenditure per pupil, the level achieved in 1981.

The administration also proposes to consolidate vocational and adult education and to cut real spending between 1981 and 1983 by 50 percent. Previous administrations, as well as the Congressional Budget Office, have viewed vocational education as a likely candidate for budget cuts because it is assumed that most states would make up the 10 percent of total costs represented by the federal contribution. Roughly half the federal support is unrestricted, while the other half is bound by various set-asides for disadvantaged students and for activities of particular federal interest. Protected groups are likely to bear a disproportionate share of the cuts if the proposed block grant eliminates the set-asides.

The Reagan administration is proposing to continue the policies for education it established last year—consolidation, large budget cuts, and reduced federal influence on state and local decision-making. A logical extension of these policies would be the eventual elimination of any federal involvement in elementary and secondary education, for as budgets shrink and the focus on target populations weakens, the rationale for federal participation is lost. In 1981 Congress went along with the president with little debate as legislative changes were made under the pressure of the budget reconciliation procedure. This year Congress will have a second chance to consider whether the older purposes are still valid and whether new national needs in education are emerging that may require federal support.

As stated earlier, for at least the last decade, the dominant rationale for federal support of elementary, secondary, and higher education has been to equalize educational opportunity. Federal programs were created because schools and colleges, financed and governed by local, state, and private agencies, were not meeting this objective. Federal financial support enriched the education of low-income, low-achieving children in primary and secondary schools and provided aid for low-income students who could not otherwise have paid for college. These programs have not met all the early expectations held for them, and many need reform. Now, because of the president's budget, Congress must address the question whether to slash these programs as no longer

38-036 O - 84 - 98

affordable luxuries and return essentially all responsibility for education to state, local, and private sources. Fewer federal dollars and increased state and local discretion are almost certain to reduce spending for education in many states and to diminish opportunity for low-income or disadvantaged groups.

Higher Education

The 1983 budget continues the policy begun last year of reducing both the number of college and university students receiving federal assistance and the aid that the remaining beneficiaries will receive (see table 4-8).[41] Most financial aid to students comes through need-based grants or subsidized loans or through such entitlements as the GI bill and social security student benefits. Between 1981 and 1983 the administration proposes to cut these programs by 44 percent in real terms. Additional reductions are scheduled for later years. If the president's program is adopted, the number of awards, other than guaranteed student loans and health training grants, will drop from an estimated 6.1 million to 3.3 million between 1981 and 1983, a decline of nearly 46 percent. An unduplicated count of student recipients does not exist. Nor is it known how many students would be forced by the cuts to withdraw or to cancel plans to attend college, how many would be forced to enroll part-time rather than full-time, and how many would shift from higher-priced to lower-priced colleges. Some of the students whose aid is cut off under these programs might receive aid under the vestiges of other programs. The fate of individual colleges and universities would be strongly affected as well, for the cuts coincide with the decline in the eighteen- through twenty-one-year-old population, and would thereby accentuate the anticipated drop in enrollments.[42]

The main changes proposed by the 1983 budget for higher education are (1) a sharp cut in Pell grants that would reduce the number of students receiving this form of need-based aid by nearly 1 million, and a decline of 16 percent in the real value of the maximum grant between 1981 and 1983; (2) the elimination of

41. Excluded are support for research conducted in universities and tax expenditures that benefit higher education.

42. Because most of the grant programs are forward funded, the effect of cuts in budget authority proposed for 1983 would not be felt until the 1983–84 academic year.

supplemental educational opportunity grants, national direct student loans, and the state student incentive grant programs, all of particular importance to private colleges and universities; (3) reduced subsidies for the guaranteed student loan program and the exclusion of graduate and professional students from borrowing under it; (4) the beginning of the four-year phaseout of social security student benefits enacted last year on the ground that

needy recipients, 72 percent of whom are from families poor enough to qualify for need-based grants, could turn instead to grants and loans; and (5) cuts in health professions training programs of nearly 75 percent in real terms from the 1981 figure. No new health professions student loans would be made, nursing student loans and exceptional need scholarships would be eliminated, the national health service corps would receive no new starts, nursing programs would be cut from $50 million to $12.5 million, and no subsidies for physician education would be provided.

The proposed cut in Pell grants would more than reverse the expansion of aid to middle-income students enacted in 1978. The Middle Income Student Assistance Act extended aid to students from families with incomes up to $25,000; the current proposal could limit grants to families with incomes of $15,000 or less, depending on the formula adopted. When the program was created in 1972, the maximum grant was $1,400; after adjustment for inflation, the value of the $1,600 maximum award proposed for 1983 is half that initial award. With the average cost of a year in college currently at $5,500, even the maximum Pell grant available to the neediest students covers less than 30 percent of direct costs.

Costs of the guaranteed student loan program have soared in recent years as the number of borrowers has increased and climbing interest rates have driven up the interest subsidy. Proposals this year to curtail costs include increasing from 5 to 10 percent the fee paid to banks for originating loans, applying a needs test to every borrower, charging a market rate of interest after the second year of repayment, and eliminating graduate and professional student borrowing. Graduate students would be allowed to borrow under a new auxiliary loan program that carries a higher interest rate (14 percent as opposed to 9 percent) and no in-school interest subsidy (the loan enters repayment sixty days after borrowing). Because of the repayment provisions, many banks may be unwilling to lend to graduate students under this program, which operates now in less than half the states.[43]

The need to limit costs in the guaranteed student loan program is clear, but the flat exclusion of graduate students from the

43. Efforts are being made to secure participation of lenders in all states.

program would simply cut off in mid-course an estimated 600,000 graduate and professional students at the very time that there is a perceived shortage of scientists and engineers. Measures to reduce the interest subsidy, while preserving eligibility for graduate students, would reduce use of the program, lower costs, and would preserve options for students who need to borrow to attend a university.

How would the various sectors of higher education fare under the Reagan budget if enacted in its current form? Private colleges would be hit particularly hard, since their students have come increasingly to depend on federal student aid to help cover tuition. The National Institute of Independent Colleges and Universities has estimated that the 1.1 million students receiving aid at private colleges and universities in 1980–81 would lose about $1.3 billion in federal aid, leaving 500,000 students unable to cover the cost of an independent college in 1983–84.[44] Graduate and professional schools would also suffer large drops in enrollments if borrowing under the guaranteed student loan program is prohibited. Public universities would be affected by cuts in both grants and loans, while community colleges would be affected most by the cuts in Pell grants. Bankruptcies and closures of small, nonselective, private liberal arts colleges would increase. Community colleges alone might gain, as students who lack resources shift to relatively inexpensive institutions. Access to elite institutions, both at the undergraduate and professional levels, by students who are not wealthy will be curtailed. If most of the reductions proposed in the 1983 budget are adopted, the proportion of the generation of students nearing college age that will be able to acquire a higher education will be smaller than it has been in recent generations.

In defining the federal role in education, Congress may also consider issues relating to the quality of education. How can brighter and more capable people be lured into teaching? How can links be established and strengthened between the school curriculum and the increasingly technical employment market? At the college and university level, concerns are growing about the obsolescence and deterioration of research equipment, library

44. Virginia Hodgkinson, "The Impact of the President's Budget Proposals upon Students Attending Independent Colleges and Universities" (Washington, D.C.: National Institute of Independent Colleges and Universities, March 1982).

collections, and the physical plant, as well as with the vitality of an aging faculty.

In short, federal educational policy today must address two central questions. Is the goal of equality of educational opportunity still a national concern? And should the national government help states and localities to achieve and maintain high-quality education from primary through professional school? Whether Congress agrees with the administration's negative answers to both questions remains to be seen.

Employment and Training Programs

The federal government supports a variety of locally administered manpower training programs under the Comprehensive Employment and Training Act (CETA).[45] In 1981 President Reagan proposed to eliminate public service employment, and Congress agreed. Because of this change and a large drop in training, real expenditures on employment and training programs will fall from $7.9 billion in 1981 to $2.4 billion in 1983.

CETA is due for reauthorization this year, and the president has proposed further cuts in his 1983 budget. He also seeks to eliminate the work incentive program that provides training and jobs for people otherwise dependent on welfare; in its place states would be empowered to require welfare recipients to take special jobs under community work and training programs. He also proposes to reduce sharply the size of the state-federal employment service.

COMPREHENSIVE EMPLOYMENT AND TRAINING. The details of the administration's CETA proposal are contained in a reauthorization plan recently submitted to Congress. Most of CETA's titles will be consolidated into a single block grant to states to pay for the training of welfare recipients and economically disadvantaged out-of-school youths. The proposed plan would permit states to spend a small fraction of the federal grant on other disadvantaged groups. Presumably states would distribute the funds to local

45. CETA provides public service jobs for economically disadvantaged adults in two programs, one designed to handle cyclical unemployment, the other for structural unemployment. Titles II-A, II-B, and II-C give workers training and work experience. Programs for migrant farm workers and native Americans are grouped under Title III. Title IV gives on-the-job work experience for unemployed youth; the Job Corps is administered under this title. Title VIII created the young adult conservation corps.

authorities similar to existing CETA prime sponsors, who would provide training services or contract with others to provide them. States and localities would be prohibited from spending federal funds on public service employment, training stipends, or "work experience" programs. Thus enrollees in local programs would be restricted primarily to on-the-job training with private employers or to formal classroom training in training institutions. A major feature of the proposal is to give substantial control in design and control of the training programs to private business. Real outlays on CETA programs would decline from $8 billion in 1981 to $1.9 billion in 1983.

These changes depart radically from past practice. In 1980 work experience and public service employment constituted two-thirds of the service years provided under CETA. Training stipends, usually set at the minimum wage, have accounted for about half the cost of classroom training to CETA enrollees. Many present CETA participants who are neither young nor welfare recipients would be prevented from participating in training under the president's 1983 proposals.

Contrary to popular belief, manpower programs have been effective in improving enrollees' earnings, though frequently by modest amounts. An exhaustive recent study concludes that four of CETA's five basic employment and training programs—including public service employment—succeeded in raising the post-program earnings of enrollees by 6 to 18 percent.[46] Only CETA's work experience programs failed to raise enrollee earnings. Questions remain about whether the gains in earnings justify the costs. But it does appear that these programs have made progress toward their main objective. In addition, public service employment earnings and training stipends in some measure replace welfare payments on which beneficiaries otherwise would be forced to depend; and public service employees and work experience trainees often provide valued local services for financially hard-pressed counties and municipalities.

WORK INCENTIVE PROGRAM. This program provides manpower counseling and training for AFDC recipients. Participation is

46. Westat, Inc., *Impact on 1977 Earnings of New FY1976 CETA Enrollees in Selected Program Activities*, Employment and Training Administration, Office of Policy, Evaluation, and Research (ETA, 1980).

mandatory for most able-bodied adult AFDC recipients without very young children, and is voluntary for others. The president proposes to eliminate this $381 million program in 1983. The budget states that the work incentive program will be unnecessary in 1983 once states have set up mandated community work experience or "workfare" programs. Presumably the training that would otherwise have been provided by the federal program would then be provided in these community public service projects, where AFDC recipients would be required to work off their welfare grants. Past experience suggests that little if any training would be given on state or local work projects.[47] Although such social services as child care will be curtailed with the elimination of the work incentive program, the effects on AFDC recipients may be mitigated by the concentration on them of such CETA training benefits as remain.

EMPLOYMENT SERVICE. The employment service provides labor market information, especially for low-wage workers who are not well served by private alternatives. Since the 1930s the employment service has told workers and potential workers about available jobs and has sought to make the labor market operate more efficiently by reducing frictional unemployment. Because higher-wage workers tend to find employment through other means, the employment service disproportionately serves low-wage workers and their employers.

The administration proposes to reduce real federal outlays for this service from $804 million in 1981 to $511 million in 1982, and to $426 million in 1983 and subsequent years, a cut of nearly half. The employment service recently has had low placement rates, but there is some evidence that it has nonetheless shortened the duration of unemployment for people it served.[48] What makes this proposed budget reduction puzzling is that job referral assistance is one of the cheapest methods of helping disadvantaged workers

47. See Ketron, Inc., *Food Stamp Workfare Demonstration Project: Interim Report on the Short-Term Impact of the Program* (Wayne, Pa.: Ketron, 1981), pp. 28–31; Wellington Webb and Carla Bodaghi, "Utah Work Experience and Training Assessment," Department of Health, Education, and Welfare, Region 8 (Denver, Colorado: HEW, 1978); and Barry Friedman and others, *An Evaluation of the Massachusetts Work Experience Program* (Center for Employment and Income Studies, Brandeis University, 1980).

48. Terry Johnson and others, *A Pilot Evaluation of the Impact of the U.S. Employment Service* (Menlo Park, California: SRI International, 1979).

to raise their earnings. Since the administration proposes to reduce or to abandon such assistance as training and public service employment, an increase in efforts to make the private labor market work more effectively would seem prudent. The employment service is the most important existing state-federal instrument for accomplishing this goal.

EFFECTS OF THE CHANGES. Because benefits from the work incentive and CETA programs accrue largely to the unemployed and economically disadvantaged, the population that suffers most from the cutbacks is easy to identify. It is the same population hurt most by recent and proposed changes in means-tested transfer programs, namely low-income families with a potential earner.

Taken in combination with the proposed changes in transfer programs, the scheduled reductions in manpower programs appear to represent a systematic withdrawal of both income assistance and manpower services from the working poor in the midst of the most serious economic decline since the 1930s.

Conclusion

Emboldened by his success in securing approval for most of the program he proposed in 1981, President Reagan is returning for even larger cuts in domestic programs than he obtained last year. These reductions do more than extend last year's program. Most of the cuts enacted in 1981 reduced the size of the programs they affected but did not change their basic structure. Last year the president persuaded Congress that many programs could be trimmed without undermining their capacity to achieve their basic goals. Furthermore, he assured Congress and the American people that certain programs, basic to economic security, would be preserved as a "social safety net."

Proposals advanced after his budget amendments last year together with the 1983 budget make clear that President Reagan intends to eliminate major social programs and shrink even those that constitute the safety net. In some cases federal spending is to be curtailed enough to require a change in traditional objectives. In others the federal government will withdraw completely and leave to states the decision about whether any services at all are to be provided. The 1983 budget for domestic programs must be

viewed not merely as one element in an overall economic plan, but as the boldest and most controversial attempt in fifty years to roll back the place of the federal government as a guarantor of equal opportunity and provider of social services.

SPACE SHUTTLE: NASA VERSUS DOMESTIC PRIORITIES

President Nixon's announcement on Jan. 5, 1972, that he favored giving the National Aeronautics and Space Administration (NASA) $5.5-billion over the next six years to develop a space shuttle produced a mixed reaction from Congress.

Supporters of the space shuttle hailed the decision as a milestone in America's space program while critics termed the program wasteful and an example of misplaced priorities.

Plans for the space shuttle call for a reusable two-stage vehicle consisting of a booster and an orbiter.

The orbiter would carry a two-man crew and two passengers with the capability—when modified—of carrying six to 12 passengers. It would be able to remain in space for up to 30 days.

NASA hopes to schedule the first manned space shuttle flight by April 1978 and expects the space shuttle to be entirely operational by the end of the decade.

In a statement announcing his support for the space shuttle, Nixon said: "It will revolutionize transportation into near space, by routinizing it. It will take the astronomical costs out of astronautics."

Congressional critics of the space shuttle question its usefulness and are planning a campaign to keep the shuttle from being built.

References. *State of the Union address (science and technology section), Weekly Report p. 128; fiscal 1972 NASA authorization, 1971 Weekly Report p. 1478, 1265; fiscal 1971 NASA authorization, 1970 Almanac p. 200.*

The Issues

The dispute over the space shuttle involves three major issues.

Manned Space Program. Dr. James C. Fletcher, the NASA administrator, stated in a Jan. 5 press conference: "The shuttle is the only meaningful new manned space program which can be accomplished on a modest budget." Critics of the shuttle argued that the future U.S. space effort should concentrate on unmanned flights. Sen. Walter F. Mondale (D Minn.) commented Jan. 16 in a television interview on *Issues and Answers*: "I think that a space program of $2- to $3-billion a year, largely an unmanned, instrument flight, but also in some manned flight, could give us a fully sophisticated and very useful program."

Space vs. Domestic Needs. Supporters of the space shuttle described it as a logical extension of U.S. efforts in space and important for technological advancement. Sen. Edward J. Gurney (R Fla.) commented Jan. 16 on *Issues and Answers*: "It is extremely important to the United States to have a continuing and viable space program because technology, of course, is the strength of any great industrial nation.... We must continue in space and this is the next sensible and logical step."

Opponents criticized Nixon for requesting funds for the program instead of for domestic needs. Sen. William Proxmire (D Wis.) Jan. 8 in a press release called the decision "an outrageous distortion of budgetary priorities." He added, "...the President has chosen the space shuttle over money for schools, health, housing, mass transit, open space, environmental needs or other vital programs."

NASA's Future. Supporters of the space shuttle say NASA's future and its political and technological prestige are riding on the debate. Opponents confirm this, arguing that if they can stop the shuttle, NASA will have to be content to operate without expensive projects.

Manned Space Program

The manned space flight program which involved the Mercury, Gemini, Apollo and Skylab projects consumed the largest percentage of NASA's research and development funds since the U.S. space program began.

The prestige of NASA and the technological eminence of the United States climbed in the international community on July 20, 1969, when astronauts Neil A. Armstrong and Edwin E. Aldrin Jr. landed on the moon.

The moon landing also created problems for the manned space program. One problem involved the old debate over the future of the space program and national priorities. The opinions of some of the space program's staunchest supporters wavered. Sen. Clinton P. Anderson (D N.M.), chairman of the Senate Aeronautical and Space Sciences Committee, had commented in 1971 in an interview with Congressional Quarterly: "I was very much in favor of putting a man on the moon, but I don't see the second step. Do we go to Jupiter or Mars? It is a very expensive process and I don't think that we can afford it now."

The second problem posed by the moon landing was the creation of a "what a tough act to follow" attitude on the part of some space planners.

A report entitled "The Post-Apollo Space Program: Directions for the Future" presented to the President on Sept. 15, 1969, stated that "manned exploration of the planets is the most challenging...of the many long-range goals available to the nation." The report suggested setting a date for a manned Mars landing.

Another plan advanced by advocates of manned space flight for the 1970s involved the development of a reusable space shuttle and a space station. Dale D. Myers, NASA's associate administrator for manned space flight, told the House Science and Astronautics Committee in February 1970 that the United States must continue to have a strong manned space flight program to promote new technology and to maintain its competitive position.

Chapman

He strongly endorsed the space shuttle as a project with applicability for scientific and military purposes.

The Apollo program will be concluded with the launchings of Apollo 16 and 17 in 1972. The Skylab experimental space station program will be concluded in 1973. Without the shuttle, the United States will have no program of manned space flight after 1973. Budgetary restrictions have ruled out construction of a space station, a NASA spokesman said. Space planners are also aware that programs for the manned exploration of Mars would be far too costly to get through Congress in light of the difficulties that the space shuttle is facing.

Unmanned Programs. Critics of the space shuttle contended that the program was being advanced at the expense of unmanned programs. Mondale, a leading critic of the space shuttle, repeatedly expressed this fear:

"Virtually all of the useful things we have gotten out of space; communications, earth surveillance, weather stations, navigation, the technology of instrumentation and miniaturization, most of this has come about through unmanned instrumented flight." (Jan. 16, on *Issues and Answers*)

Shortly after the fiscal 1973 budget was released, Mondale stated in a Jan. 25 press release: "The FY 1973 budget reveals that in order to absorb the gigantic costs of the shuttle, NASA is cutting the heart out of vital scientific programs to explore the mysteries of the universe with unmanned space missions. The grand tour (unmanned) of the solar system—long advocated by space scientists—is one major casualty of the wasteful decision to build the shuttle. And because of the shuttle, NASA is delaying the launching of two orbiting solar observatories."

Shuttle vs. Domestic Priorities

Supporters of the shuttle point to the reduced launching costs because of the shuttle's reusable features and the scientific benefits to be derived from the shuttle's mobility. They argue that the nation's space program has been cut back far enough because of an emphasis on social priorities.

Opponents of the shuttle contend it is wrong to commit the nation to another expensive space program when many problems need to be solved on earth. They emphasize that with more money needed for education, housing and mass transit, the space program should have

Presidential Politics and the Space Shuttle

The space shuttle has emerged as an issue in presidential politics during discussions of national priorities and because of its importance as an economic issue in Florida, which holds the nation's second presidential primary March 14.

Statements on the space shuttle by President Nixon and five of the announced Democratic presidential contenders follow:

Nixon. When he announced the space shuttle development plans Jan. 5, Nixon said: "...commitment to the space shuttle program is the next right step for America to take, in moving out from our present beachhead in the sky to achieve a real working presence in space —because the space shuttle will give us routine access to space by sharply reducing costs in dollars and preparation time."

Humphrey. In a position paper, Sen. Hubert H. Humphrey (D Minn.) said: "...three essential arguments in favor of the space shuttle have convinced me of the value of the program...the space shuttle will be economically efficient...have a tremendous impact on the future exploration of space...mean that many of those who are now unemployed...will be reemployed." Humphrey was not a member of the Senate at the time of the vote on the fiscal 1971 NASA authorization and was recorded as not voting on the agency's fiscal 1972 authorization.

Jackson. Sen. Henry M. Jackson (D Wash.) prepared an article for *The Machinist*, a magazine published by the International Association of Machinists, in which he wrote: "...the space shuttle is important to America...vital to science...important to working men and women...a good investment which will return its cost to the people many times over." Jackson voted against amendments to delete funds for the shuttle from the fiscal 1971 and 1972 NASA authorizations.

Lindsay. A spokesman for New York Mayor John V. Lindsay, said Lindsay believes the space shuttle is too costly a project in view of the country's pressing domestic needs. Lindsay favors a smaller and less expensive unmanned space exploration program.

McGovern. Sen. George McGovern (D S.D.) supported an amendment to delete funds for the shuttle from the NASA authorization in fiscal 1971 and announced for a similar amendment in fiscal 1972. Spokesmen at McGovern's Washington campaign headquarters and Senate office told Congressional Quarterly McGovern opposed development of the space shuttle.

Muskie. Sen. Edmund S. Muskie (D Maine) stated Jan. 28 in Miami, Fla.: "...in terms of current priorities and demands upon our national resources, I don't think it (space shuttle) has as high a priority as others such as the subject we are discussing here today (the environment)." Muskie voted for amendments to delete funds for the shuttle from the fiscal 1971 and 1972 NASA authorizations.

a lower priority. The opponents express the fear that the program's actual cost has been understated.

Both sides have used space shuttle cost figures to reinforce their support or opposition to the program.

Benefits. NASA estimated the research and development costs for the space shuttle at $5.5-billion over the next six years (fiscal 1973-78). Some $1-billion was added to that figure by NASA to serve as an increase allowance to cover unforeseen research and development problems. Two complete shuttles would be produced during the research and development stage.

NASA estimated that an additional $1.5-billion would be needed at a minimum for the procurement of three additional shuttles, facilities to launch and land the shuttles and extra equipment. The total investment cost of the shuttle is $7-billion and $8-billion when the contingency fund is included, according to NASA.

NASA stated that the shuttle could be developed and several other programs in space science applications and aeronautics maintained if NASA's total budget authority remained at $3.4-billion through the 1970s. *(NASA funding, illustration p. 439)*

Nixon's budget request for the space shuttle in fiscal 1973 was $200-million. NASA estimated that the highest level of funding for the shuttle would be $1.3-billion in fiscal 1976.

To make room for the cost of the shuttle, NASA canceled other programs. The canceled programs included the grand tour (an unmanned mission to the outer planets scheduled for the late 1970's) and the NERVA program to develop a nuclear rocket engine. The grand tour, estimated to cost $700-million, was replaced with a $7-million mission to Jupiter and perhaps Saturn. The NERVA project, on which $1.4-billion had already been spent, was canceled outright.

Once in use, the space shuttle would replace all the current launch rockets used to thrust satellites into space.

Cost Effectiveness Study. A NASA cost effectiveness study based on slightly more than 40 satellite launchings per year, the yearly average of the U.S. unmanned program over the last eight years, showed that the shuttle was economically feasible. It assumed NASA, the Defense Department and other agencies would fly 500 shuttle missions over a 12-year period between 1979 and 1990.

The study estimated that conventional launchings over the 12-year period using rockets would cost $11-billion. The total shuttle launching costs would be $5.8-billion or $5.2-billion less than the conventional method.

Payload development and procurement costs for the 500 missions during the 12-year period would be $29.8-billion for conventional launches. The comparable

COPYRIGHT 1972 CONGRESSIONAL QUARTERLY INC.
Reproduction prohibited or allowable as in part except by editorial clients.

figure for the shuttle was set at $22.6-billion. The study said that the $7.2-billion savings with the shuttle system was due to payload reusability, design simplification and lower risk factors.

The study concluded that the shuttle would save $12.4-billion under the cost of conventional launching in the 1979-1990 period.

Priorities. Mondale, one of the most vigorous critics of the space shuttle, expressed anger at Nixon's veto of a $2.1-billion child care bill at the end of the first session of the 92nd Congress. After the President announced that the nation would develop a space shuttle, Mondale compared the decision and the child care veto in a Jan. 6 press release:

"Typically, this administration can squander $6.5-billion to fly four people in orbit, while it refuses to invest less than one third that amount to provide desperately needed day care and development programs for millions of pre-school children...."

Proxmire in a Jan. 8 press release calling the shuttle "the last thing we need at this time" stated: "The President has clearly re-ordered our priorities. But he has re-ordered them in the wrong way."

Critics' Cost Estimates. Critics of the space shuttle said more expense is involved than the research and development costs. They set out to attack NASA's $5.5-billion to $6.5-billion research and development estimate and to emphasize long-range program costs.

Mondale stated in a Jan. 25 press release: "The briefings and materials on NASA's FY 1973 budget have exposed two myths concerning the proposed space shuttle.

"The first myth was that the shuttle would 'only' cost $5.5-6.5-billion. But now, NASA admits that the shuttle's cost over a 10-year period of operation will be $10-14-billion—more than double the figure ballyhooed by NASA and the Nixon administration over the past several weeks.

"But even that figure is deceptive....

"It does not include the cost of the shuttle's payloads, which will add another $20-28-billion to the shuttle's total costs....

"...we are really talking about a massive effort in space which could cost anywhere from $35- to $52-billion.

"The second myth has been that opponents of the shuttle are anti-space exploration...."

NASA's Future

More than NASA's pride is riding on the space shuttle. For the ailing aerospace industry, the space shuttle represents one of the few chances many companies have to obtain a lucrative government contract in a drastically reduced space program.

President Nixon emphasized that the space shuttle would have a great impact on the aerospace industry.

Dr. Fletcher added: "Perhaps the greatest benefit may very well come in making good use of the professional skills and professional employees, some of whom are wondering about where the aerospace world is going. I think it is proper to say at this time that we anticipate that at its peak, the direct employment on the space shuttle will be of the order of 50,000 individuals."

A NASA spokesman explained that the 50,000 jobs meant that 108,000 persons would be employed on NASA contracts in fiscal 1973. In fiscal 1971, 112,000 workers were employed on NASA contracts. With the conclusion of the Apollo program in 1972 and the Skylab in 1973, contractor employment on NASA projects would drop to 50,000 without the space shuttle, according to NASA. Employment on NASA projects was highest at the peak of the Apollo program in fiscal 1966 when 390,000 persons were employed by aerospace contractors.

Opponents of the space shuttle criticized NASA for planning a "senseless extravaganza" to perpetuate its own interests.

Mondale issued a press release on Jan. 6 which read: "As with so many other expensive weapons and gadgets, the construction of the space shuttle has more to do with perpetuation of bureaucratic interests and the politics of government contracting than with the authentic needs of our nation."

Proxmire in a Jan. 8 release said: "The main rationale for the shuttle is that it will keep our space program going. It will keep the NASA technicians occupied. It will keep the aerospace industry happy."

Congressional Views

Sen. Edward J. Gurney (R Fla.): "We are in space to stay," Gurney said in an interview Jan. 28. "The space shuttle is an improved and reusable vehicle to carry both space satellites and men into earth orbit," he added.

Gurney explained that the shuttle booster would replace all of the launch rockets currently in use. It would be used to launch communications, weather, resources, astronomical and military satellites.

"The space program is way down at the botton of the totem poll already" with regard to the nation's priorities, Gurney said. He said Americans spend 43 cents out of every tax dollar on social and welfare programs and only one and one-half cents on the space program. "One-third of one cent will be all that we are going to spend for the space shuttle," Gurney said.

He criticized the space shuttle cost estimates used by the critics for "including ongoing costs and payload costs with what the shuttle is going to cost through the research and development stage." Gurney said that there would be additional payload costs whether the space shuttle or another type of booster launched a satellite.

Rep. Louis Frey Jr. (R Fla.) is a member of the House Science and Astronautics Committee and its Manned Space Flight Subcommittee.

"We have to go from an experimental to an operational use of space," Frey said in an interview Jan. 26. "There is a continuing need to keep man in space."

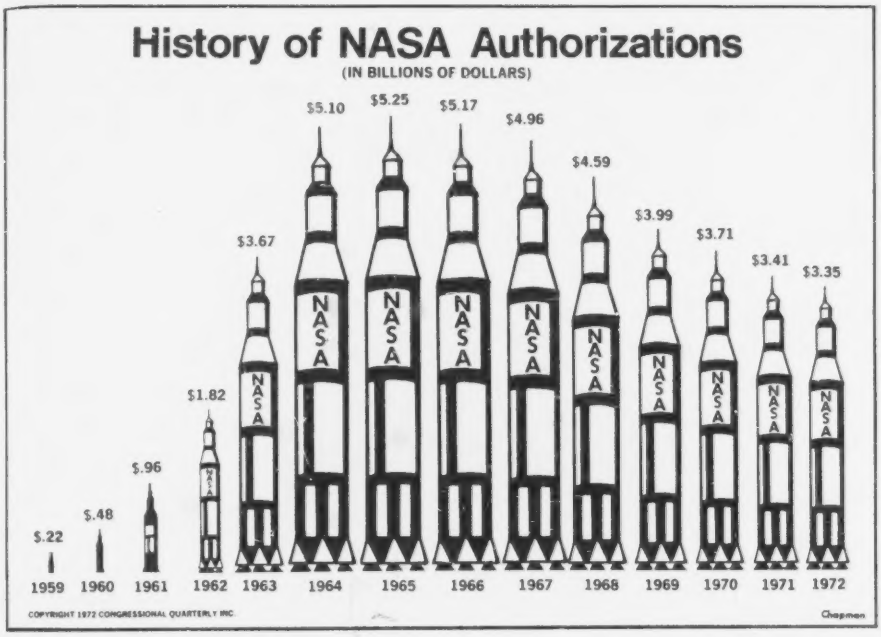
"There are many things that a man can do in space better than machines," Frey said.

Frey said that the shuttle can be justified because it will "replace many launch vehicles" and make "payloads less expensive."

He rejected the priorities argument advanced by critics of the shuttle. He stated that the proposed space shuttle program was modest enough to fit in with other national priorities.

Sen. Walter F. Mondale (D Minn.), in an interview Jan. 28, said that he was not anti-space, but

COPYRIGHT 1972 CONGRESSIONAL QUARTERLY INC.
Reproduction prohibited in whole or in part except by editorial clients.



that he opposed the shuttle because it was a waste. He added that he supported the Apollo program.

Congress supported the effort to land men on the moon because it involved a "crisis of prestige" and it was important to "recoup our posture as the pre-eminent technological society in the world," Mondale said.

He said he did not believe that the shuttle could be justified as useful or of scientific value.

Mondale characterized the shuttle as "a manned extravaganza to get public support." He said that the money should "go for priorities at home."

He added, "It should go to solve human problems such as mass transit, housing, education and the environment."

Rep. Edward I. Koch (D N.Y.) opposed the shuttle as a member of the House Science and Astronautics Committee during the 91st Congress. He now serves on the Banking and Currency Committee.

Koch said in an interview Jan. 26 that his opposition was based on priorities. He added, "Until we have mass transit to LaGuardia and Kennedy (Airports), I'm not interested in the space shuttle."

Koch said that $600-million was spent on mass transit in fiscal 1972 and one-third that amount or $200-million has been requested for the space shuttle in fiscal 1973. He characterized this as an outrage. Koch added, "How many people can you get in a space shuttle anyway?"

He said that he was not opposed to space exploration but felt that getting rats out of slum apartments, dealing with heroin addiction and building housing was more important than the space shuttle.

NASA Reaction

Fletcher said some critics of the space shuttle were "deliberately confusing the facts." He added, "Our best estimate is that it will cost $5.5-billion for research and development of the shuttle. Another $1-billion, a 20-percent increase allowance, has been added to take care of unforeseen research and development problems."

"The shuttle will more than pay for itself with 40 flights per year," Fletcher said. This figure included civilian satellite launchings by NASA and military launchings of Defense Department satellites.

"I am completely convinced that the shuttle is the right thing to do. If I wasn't, I wouldn't have gone ahead with it," he added.

"It is a big program; $5.5-billion is a lot of money, and as a taxpayer, I think questions ought to be asked. I just don't like the distortion of the data," Fletcher said.

Fletcher said opponents of the space shuttle "exaggerated the real research and development costs of the shuttle" and "added in satellite costs with shuttle costs." He continued, "These satellites would be launched with or without the shuttle."

V. RESOURCE ALLOCATION AMONG COMPETING NATIONAL PRIORITIES 29

INTRODUCTION

This bibliography is designed to help college debaters with research on the 1984-1985 Intercollegiate Debate Topic: "Resolved: that the U.S. Federal Government should significantly increase the exploration and/or development of space beyond the Earth's mesosphere."

The selected items have been arranged in five sections: history and overview; space law; space exploration and development, including space policy and economic aspects, technology, industrialization, space station, living in space, planetary exploration, and foreign space programs; militarization of space; and resource allocation among competing national priorities. By agreement with the Project Coordinator for the Committee on Intercollegiate Debate and Discussion of the Speech Convention of America, this document does not take into account questions of specific alternative uses of the current or proposed Federal funds devoted to U.S. space programs, and the effect that such alternatives might have upon the scope, direction, or viability of the U.S. space program.

This annotated bibliography is composed of selected periodical articles and books. The majority of the citations were obtained from the computerized Congressional Research Service Bibliographic Data Base, created and maintained by the Library Services Division. Other material was selected from collections within the Congressional Research Service and elsewhere in the Library of Congress.

The authors wish to thank Dagnija Sterste-Perkins, Analyst in International Relations, Foreign Affairs and National Defense Division; Jane Gravelle, Specialist in Taxation and Fiscal Policy, Economics Division; Daniel Zafren, Specialist in American Public Law, American Law Division; and Gene Falk, Technical Information Specialist, Education and Public Welfare Division for their assistance in the preparation of this bibliography. Thanks are also extended to Richard Gigax, Head, Subject Specialization Section, Library Services Division, who did the final editing, and John M. White and Barbara Hall, Library Services Division, who provided the secretarial production.

Items in this bibliography may be located at a nearby public, research or depository library. The Congressional Research Service cannot provide debaters with copies of the items listed.

I. HISTORY AND OVERVIEW

Anderson, Frank W., Jr. Orders of magnitude: a history of NACA and NASA, 1915-1980. Washington, National Aeronautics and Space Administration, 1981. 106 p. (NASA history series. NASA SP-4403)

Presents an updated history of aeronautical and astronautical research by the United States, both under NASA and its predecessor, National Advisory Committee for Aeronautics.

Bekey, Ivan. Integrating space developments: 1980-95. Astronautics & aeronautics, v. 16, Feb. 1978: 50-67.

Summarizes a report for NASA by the Aerospace Corp. which sets forth a systematic development plan for the U.S. space program. The report was to "bridge the gap between today's technology and advanced concepts and to lay out corresponding time-phase needs for new types of orbital transportation, support vehicles, and facilities."

Brodsky, Robert F., and Bernard G. Morais. Space 2020: the technology, the missions likely 20-40 years from now. Aeronautics & astronautics, v. 20, May 1982: 54-73.

Sets out what could happen in space in the next 40 years. Foresees continued development of the military uses of space, further exploration of the solar system and manufacturing in space.

Hacker, Barton C., and James M. Grimwood. On the shoulders of Titans: a history of Project Gemini. Washington, U.S. National Aeronautics and Space Administration, Scientific and Technical Information Office [for sale by the Supt. of Docs., G.P.O.] 1977. 625 p.

"NASA SP-4203"

Includes bibliography (p. 495-513) and index.

Human uses of outer space. Society, v. 21, Jan.-Feb. 1984: 8-44.

Partial contents.--The winds of star wars, by J. Katz.--Military uses and implications of space, by T. Blau and D. Goure.--America's international space activities, by M. Smith.

Kennedy, John F. Special message to the Congress on urgent national needs, May 25, 1961. Public papers of the Presidents of the United States. January 20 to December 31, 1961. Washington, G.P.O., 1962. 396-406 p.

In this speech (205) Kennedy called for increased funding for the U.S. space program that would lead to the landing of men on the moon by the end of the 1960s. Calls on the U.S. "to take a clearly leading role in space achievement."

Mueller, George. The 21st century in space. Aerospace America, v. 1, Jan. 1984: 84-88.

Describes probable space activities of the 21st century. Foresees weapons in space, communications platforms, space factories and lunar based space activities.

Ruppe, H. O. A history of the communication satellite. Journal of the British Interplanetary Society, v. 30, Apr. 1977: 131-134.

Presents brief outline of the history of the development of communication satellites.

Schichtle, Cass. The National Space Program: from the fifties into the eighties. Washington, National Defense University, for sale by the Supt. of Docs., G.P.O., 1983. 122 p. (National security affairs monograph series, 83-6)
Contents.--Policy development retrospective.--The evolution of the US space organization.

Smith, Marcia. Space activities of the United States, Soviet Union, and other launching countries/organizations, 1957-1983; report prepared by the Congressional Research Service, Library of Congress, for the Subcommittee on Space Science and Applications, transmitted to the Committee on Science and Technology, U.S. House of Representatives, 98th Congress, 2nd session. Washington, G.P.O., 1984. 136 p.
At head of title: Committee print.

Space 25. IEEE spectrum, v. 20, Sept. 1983: 26-98.
Contents.--Crossroads in space.--Space technology.--The politics of space.--The future of space.

Space--past, present, and future, by Michiel Schwartz and Paul Stares, editors. Futures, v. 14, Oct. 1982: whole issue.
Partial contents.--The first quarter century of spaceflight, by M. Smith.--The militarization of space, by G. Steinberg.--The industrialization of space, by R. Williamson.--Space: battlefield of the future? by B. Jasani.--Alternative space futures: the next quarter-century, by I. Miles and M. Schwarz.

Wilson, Andrew. The Eagle has wings: the story of American space exploration, 1945-1975. London, British Interplanetary Society, 1982. 140 p.
Supplement to Spaceflight magazine issued in 1982.
Contents.--The foundations are laid.--Better late than never.--How high the Moon?--The Moon, the planets and Ranger.--Man in space.--Target: the Moon.--Apollo: three men at a time.--Apollo and lunar orbiter.--Skylab and ASTP--Apollo lives on.--Back to the planets.

II. SPACE LAW

Agreement Governing the Activities of States on the Moon and Other Celestial Bodies; prepared at the request of Hon. Howard W. Cannon, Chairman, Committee on Commerce, Science, and Transportation, United States Senate. Washington, G.P.O., 1980. 3 v.
At head of title: 96th Congress, 2nd session. Committee print.

Bitto, Ron. Cosmic counselor. Omni, v. 3, Aug. 1981: 48, 50-51, 94.
Arthur Dula, a Houston attorney, contends that "international space law is based on academic and dangerous treaties designed to chill the development of free enterprise in outer space."

Christol, Carl Q. The growth of space law. Astronautics & aeronautics, v. 19, Dec. 1981: 111-115.
"Space law has kept up well with the rapid pace of space technology although unresolved issues remain between open and closed societies and developed and developing nations."

Colloquium on the Law of Outer Space, 18th, Lisbon, 1975. Proceedings. South Hackensack, N.J., Distributed by Fred B. Rothman & Co., 1976. 201 p.
Papers were presented on the legal aspects of the utilization of energy from space, the legal status of geostationary orbit, and general questions of international legal cooperation in astronautics.

Colloquium on the Law of Outer Space, 19th, Anaheim, Calif., 1976. Proceedings. South Hackensack, N.J., Distributed by Fred B. Rothman & Co., 1977. 419 p.

Papers and discussion covered the future of space law, space law and energy, space colonies, remote sensing, and direct broadcasting by satellite.

DeSaussure, Hamilton. Remote sensing by satellite: what future for an international regime? American journal of international law, v. 71, Oct. 1977: 707-724.

Article discusses some of the legal problems and concepts, especially sovereignty and right of privacy, brought on by remote sensing by satellite. Suggests provisions for a U.N.-sponsored remote sensing agreement.

Dula, Art, and others. Symposium: the role of private enterprise in outer space--international legal implications. Houston journal of international law, v. 2, autumn 1979: 1-166.

Contents.--Free enterprise and the proposed Moon Treaty, by A. Dula.--Earth space transport systems--concepts, criteria & constraints, by W. Good.--Product liability in space law, by P. Haanappel.--Outer space law and private enterprise in outer space: an international perspective, by G. Reijnen.--Space industrialization and the legal status of astronauts: start of a jurisdictional head scratcher, by G. Robinson.--Outer space delimitation proposals: enlightened jurisprudence or celestial shakedown? Some implications for private enterprise, by G. Sloup.--International utilization and management of space systems, by D. Smith.--Hail? No--it's Skylab, by J. Tamm.--Outer space: a preserve for all human kind, by L. Tennen.

Footer, Sheila. Legal issues and answers for commercial users of the Space Shuttle. Transportation law journal, v. 15, no. 1, 1983: 87-101.

Article contends that "the challenge for the next decade not only will be technological--it also will be legal, for there are few 'experts' now in space law. Commercial users are going to require some 'experts,' however, to answer some difficult questions before they make a substantial financial commitment to use the shuttle. NASA and the legal community must recognize the concerns of the private users, and attempt to resolve them in a manner equitable to all. The future of commercial endeavor in space depends on it."

Galloway, Eilene. Perspectives of space law. Journal of space law, v. 9, spring-fall 1981: 21-29.

This article presents major positive features of the 1967 Treaty on Outer Space. Maintains that space law has kept abreast and even ahead of space technology.

Glazer, J. Henry. Domicile and industry in outer space. Columbia journal of transnational law, v. 17, no. 1, 1978: 67-117.

This article contends that "the . . . economic exploitation of the outer space segment of transnational space presents a major and tangible challenge to contemporary national and international law-makers. A failure to establish rational foundations for utilizing the outer space segment within the present context of international law will create obstacles to future space settlement and industrialization."

International satellite communications and the new information order. Syracuse journal of international law and commerce, v. 8, summer 1981: 322-396.

Contents.--The new world information order and direct broadcasting satellites, by M. Masmoudi.--Telecommunications, outer space, and the new international information order (NIIO), by C. Christol.--International satellite communications and the new information order: distressing broadcasting satellites, by S. Doyle.--Direct broadcasting via satellite and a new information order, by R. Jakhu.--A Canadian perspective on direct broadcast satellites and the new world information and communication order, by G. Warren.

Jasani, Bhupendra, and Maria A. Lunderius. Peaceful uses of outer space--legal fiction and military reality. Bulletin of peace proposals, v. 11, no. 1, 1980: 57-70.

"Examine how relevant the international legal rules constituting the legal regime of outer space are for military activities in outer space."

Magdelenat, Jean-Louis. The major issues in the "agreed" principles on remote sensing. Journal of space law, v. 9, spring-fall 1981: 111-120.

Article concludes that "those States in favor of freedom of sensing and dissemination of data and information can point to the call for international cooperation as supportive of their position. Global and regional solutions to environmental and resource problems can only be achieved in a relatively open regime. Restrictions on sensing and dissemination are not easily reconciled with international cooperation. For there to be cooperation, there must be access to the information."

Menter, Martin. Commercial participation in space activities. Journal of space law, v. 9, spring-fall 1981: 53-68.

This article examines the impact of space treaties on the commercialization of space.

----- Commercial space activities under the Moon Treaty. Syracuse journal of international law and commerce, v. 7, winter 1979-1980: 213-238.

Article concludes that "continued international accord is essential for preventing friction in space. This is of equal concern to all States. Greater participation of non-space powers in space activity should better ensure bringing to fruition its many benefits for all mankind."

Robinson, George S. Space law, space war and space exploitation. Journal of social and political studies, v. 5, fall 1980: 163-178.

Assesses how current space law will effect long-term private risk capital investment in space exploitation.

----- Who owns the Moon? Foreign Service journal, v. 58, July-Aug. 1981: 22-25.

"In the evolution of space law, too many nations and people believed in an effective and successful ambience of cooperation for peaceful purposes in near- and deep-space activities. It distracted some of the decision-makers from proper considerations of the true military, economic, political, and ideological motivations of the primary space-law negotiators."

Smith, Delbert D. The Moon Treaty and private enterprise. Astronautics & aeronautics, v. 18, Jan. 1980: 62-65.

Advocates that the U.S. should protect its interests by clarifying "use" and "exploitation" in the U.N.'s proposed Moon Treaty.

Symposium: the new era in outer space. Akron law review, v. 13, spring 1980: 593-697.
Contents.--The new era in outer space, by H. DeSaussure.--Private management and operation of the Space Shuttle: some legal problems related to market entry, by G. Robinson.--Some aspects of third party liability in Space Shuttle operations, by T. Wolcott.--Current status of NASA Space Shuttle regulations, by G. Sloup.--STS-legal connotations, by M. Menter.--International law and military activities in outer space, by R. Bridge.--Military use of the Space Shuttle, by W. Reed and R. Norris.--The operator's liability with regard to transport of goods by Space Shuttle, by I. Diederiks-Verschoor.

United Nations. Office of Public Information. The United Nations and outer space. New York, United Nations, 1977. 40 p.
"United Nations publication. Sales no. E.77.1.9"
This booklet briefly summarizes some of the main areas of interest to the United Nations concerning outer space."

U.S. Congress. House. Committee on Foreign Affairs. The second U.N. Conference on the Peaceful Uses of Outer Space (Unispace 1982) August 9-12, 1982; report. Washington, G.P.O., 1983. 27 p.
At head of title: 97th Congress, 2nd session. Committee print.

U.S. Congress. House. Committee on Science and Technology. Subcommittee on Space Science and Applications. Unispace '82. Report and hearing, 97th Congress, 2nd session. July 14, 1982. Washington, G.P.O., 1983. 742 p.
"No. 160"

U.S. Congress. Senate. Committee on Aeronautical and Space Sciences. Space law: selected basic documents; staff report. Washington, G.P.O., 1976. 464 p.
At head of title: 94th Congress, 2nd session. Committee print.

U.S. Congress. Senate. Committee on Commerce, Science, and Transportation. Space law: selected basic documents, second edition. Washington, G.P.O., 1978. 600 p.
At head of title: 95th Congress, 2nd session. Committee print.

Wiewiorowska, Krystyna. Some problems of state responsibility in outer space law. Journal of space law, v. 7, spring 1979: 23-38.
Examines the problems relating to state responsibility for space activities undertaken by the state, its citizens or in cooperation with other states.

Williams, Maureen. The geostationary orbit: a limited natural resource from outer space. International relations, v. 6, Nov. 1979: 662-671.
Reviews agreements and conferences covering the placement of communications satellites in a geostationary orbit. The geostationary orbit has been declared a limited natural resource from outer space by the U.N. Working Group on Direct Broadcasting Satellites.

----- International law in the pursuance of sun power as a new source of energy. International relations, v. 5, May 1977: 24-39.
Discusses the application of international and space law to the utilization of solar energy on earth.

III. SPACE EXPLORATION AND DEVELOPMENT: SCIENTIFIC AND COMMERCIAL

A. Policy and Economics

Chadwick, Susan. New visions, failed dreams: what's our payoff from NASA lift-offs? Houston City magazine, v. 8, Apr. 1984: 105-107, 124, 126-128, 131-133.
Looks at probable economic benefits that the Johnson Space Center may have for the Houston area.

Colombo, Giuseppe. Space technology: where will fiction meet reality? Technology review, v. 84, Oct. 1981: 69-77.
"The fact that we have not yet undertaken many technically feasible projects to bring the resources of space to bear on our urgent needs on earth suggests that the line between reality and fiction depends not on science but on social and political factors."

Cowen, Robert C. Space: where next for the US? Christian Science monitor, Dec. 27, 1983: 16-17; Dec. 28: 14-15; Dec. 29: 14.
Contents.--NASA-ripe for a renaissance.--A new agenda for NASA beyond the pioneering stage.--Building a permanent presence in orbit--a laboratory/service station/facility.

Etzioni, Amitai. The Moon-doggle: domestic and international implications of the space race. New York, Doubleday & Company, inc., 1964. 198 p.
The author contends "that the space program in general--especially the moon project and particularly the landing of a man there--has claimed an undue amount of attention and resources; that the race into space has some dangerous side-effects that threaten the vitality of our science, undermine our security, and retard rather than advance our economy."

Evans, Michael K. The economic impact of NASA R&D spending. Prepared for the U.S. National Aeronautics and Space Administration. Bala Cynwyd, Pa., Chase Econometric Associates, 1976. 121 l.
"NASA-CR-144352"
"This study found that an increase in NASA R & D spending increases the rate of technological change and reduces the rate of inflation for two reasons. First, in the short run it redistributes demand in the direction of the high-technology industries, thus improving aggregate productivity in the economy. As a result, NASA R & D spending tends to be more stabilizing than general government spending during a period of recovery. Second, in the long run, increased NASA R & D spending expands the production possibility frontier of the economy by increasing the rate of technological progress."

Farrell-Gisse, Katrina, and Hoyt Gimlin. American options in space. Washington, Congressional Quarterly, 1983. 131-148 p. (Editorial research reports, 1983, v. 1, no. 7)

Gwynne, Peter. Shuttle woes raise doubts of cost-effective turnaround. Industrial research & development, v. 24, Jan. 1982: 68-70, 72.
Questions the economic viability of the Space Shuttle.

Hertzfeld, Henry R. Measuring NASA's impact on the economy. Unpublished paper. 1981. 18 p.
To be part of House document noted on p. CRS-v of this bibliography.
Paper presented at Annual Meeting of the Technology Transfer Society, Washington, D.C., June 16, 1981 by Henry R. Hertzfeld, Senior Economist, National Aeronautics and Space Administration.
Contends that "the space program has had beneficial returns to the economy in excess of the money spent on it."

Hussey, W. John. The economic benefits of operational environment satellites. Washington, National Environmental Satellite, Data, and Information Service, U.S. National Oceanic and Atmospheric Administration, 1983. 40 p.
Identifies and attempts to quantify benefits derived from the United States Operational Environmental Satellite System. Demonstrates how environmental satellites have helped to save lives and property from natural disasters and improved the efficiency of certain sectors of the national economy.

International cooperation in space: how to enhance the results, share the risk. Government executive, v. 16, Mar. 1984: 9, 12, 14.
Sees benefits in international cooperation in space because overseas funding and commitments provide program stability "against 'raids' on the U.S. portion of the commitment by politicians and others who would like to see the budget dollar spent elsewhere from time to time."

Keaton, Paul W. Why billions can and should be spent on space. Astronautics & aeronautics, v. 21, May 1983: 86-88, 90-92.
Contends that "over the next twenty-two years GNP will total about $100 trillion, easily supporting $130 billion for large focused space programs."

Kennan, Erlend A., and Edmund H. Harvey, Jr. Mission to the moon: a critical examination of NASA and the space program. New York, William Morrow & Co., 1969. 396 p.
"This book is harshly critical of America's space program. It is an indictment of irresponsibility at many levels, not only within the National Aeronautics and Space Administration, America's civilian space agency, but in the relationships of NASA with the Congress, the Defense Department, the aerospace industry, the scientific community, and the press." Contains a detailed study of the Apollo 204 accident of January 27, 1967 that resulted in the deaths of three astronauts Virgil Grisson, Edward White, and Roger Chaffe.

Logsdon, John M. U.S.-European cooperation in space science: a 25-year perspective. Science, v. 223, Jan. 6, 1984: 11-16.
Foresees "continued productive cooperation between the United States and Europe in space science" even though a competitive dimension has been added due to the increased level of space capability which European nations have developed.

Marsh, Peter. Scientists gain a foothold in space. New scientist, v. 99, Sept. 22, 1983: 874-879.
Notes that the scientific community is divided over the probable benefits of Spacelab.

Marth, Del. Have rocket, will rent. Nation's business, v. 71, Aug. 1983: 32-35.
"American rockets that can be used only once, like the Titan, were to be phased out of the space program but may get a reprieve because of their potential for carrying commercial payloads."

Miller, Jon D. Is there public support for space exploration? Environment, v. 26, June 1984: 2-35.
Contends that there is a strong core of support for NASA's space programs.

Moeser, John V. The space program and the urban problem: case studies of the components of national consensus. Washington, Program of Policy Studies in Science and Technology, George Washington University, 1969. 44 p; (George Washington University, Washington, D.C. Program of Policy Studies in Science and Technology. Staff discussion paper 404)

"By analyzing why the American efforts in space were sustained by a strong, cohesive, and long-lasting consensus and why the question of urban poverty fails to generate a comparable consensus, this paper suggests certain variables that seem to be essential prerequisites for any viable national consensus."

Quantifying the benefits to the national economy from secondary applications of NASA technology. Prepared by Mathematica, Inc. for the U.S. National Aeronautics and Space Administration. Princeton, N.J., Mathematica, 1976. 2 v.

"NASA-CR-2674"

The first volume is a 10 page executive summary.

"The purpose of this study is to develop preliminary estimates of the economic benefits to the U.S. from secondary applications of NASA technology. If technology is defined as the body of knowledge concerning how society's resources can be combined to yield economic goods and services, then NASA technology represents NASA's contribution to this body of technical knowledge. Secondary applications refer to uses of NASA-generated knowledge for purposes other than those primary mission-oriented ones for which the original R & D was done. These applications occur whenever a non-NASA entity, with or without encouragement from NASA, uses this knowledge in some economic activity."

Rosenberg, Tina. Mission out of control. New republic, v. 190, May 14, 1984: 18-21.

Criticizes NASA's emphasis on manned missions. Contends that the technological innovations space has given us have come from unmanned programs. Warns that "the key to economically viable space manufacturing is doing the job more cheaply than on Earth. That means robotics."

Sagan, Carl, James Beggs, and George Keyworth. Dumping space. New York, WNET/Thirteen, 1981. 7 p.

The MacNeil/Lehrer Report, Nov. 4, 1981.

James Beggs, NASA Administrator, George Keyworth, Presidential Science Advisor, and Dr. Carl Sagan discuss the future of U.S. space programs.

Schefter, Jim. It's time to stop the space retreat. Popular science, v. 221, Oct. 1982: 32, 34, 38, 40-43, 45.

Claims that the "U.S. space program in the 1980's is an ambiguous hodgepodge of brilliant events, great potential, unkept promises, and downcast vision." Points to the economic, technological, and defense benefits of a comprehensive space program.

Smith, Marcia S. 1983 space activities and a look forward at 1984. Congressional Research Service review, v. 5, Mar. 1984: 2-4, 20-21.

Reports on space launches during 1983 and predicts space activities for the U.S., U.S.S.R., the European Space Agency, China, India and Japan.

Space Shuttle. Prepared by Lyndon B. Johnson Space Center. Washington, Scientific and Technical Information Office, National Aeronautics and Space Administration, for sale by the Supt. of Docs., G.P.O., 1976. 89 p.

"NASA-SP-407"

Describes the Space Shuttle vehicle in detail and emphasizes the economic and social benefits of the Space Transportation System.

Tarter, Donald E. The Space Shuttle: prologue or postscript? World Future Society bulletin, v. 15, July-Aug. 1981: 1-6.
Fears that public apathy may set in after the initial success of the space shuttle and the consequence of this will be to close off human movement into outer space.

U.S. Congress. House. Committee on Science and Technology. Subcommittee on Space Science and Applications. United States civilian space policy. Hearings, 96th Congress, 2nd session. July 23-24, 1980. Washington, G.P.O., 1980. 246 p.
"No. 153"

U.S. Congress. Office of Technology Assessment. Civilian space policy and applications. [Washington, For sale by the Supt. of Docs., G.P.O., 1982] 391 p.
"OTA-STI-177, June 1982"

----- Space science research in the United States: a technical memorandum. [Washington, For sale by the Supt. of Docs., G.P.O.] 1982. 50 p.
Contends that "despite its many noteworthy achievements over the past 20 years, the space science program of the United States, has, as a whole, been placed in a holding pattern, and, in significant parts, been forced to retrench. Many now see space science as in a state of crisis. The National Aeronautics and Space Administration's (NASA's) overall budget for space science has, in general, been on the decline since 1974, and that of one category, planetary science, has declined precipitously."

U.S. Congress. Senate. Committee on Appropriations. Department of Housing and Urban Development, space, science veterans, and certain other independent agencies appropriations for fiscal year 1974. Hearings, 93rd Congress, 1st session. Washington, G.P.O., 1973. 908 p.
Part 1--National Aeronautics and Space Administration, Veterans' Administration.
In testimony Dr. Brian O'Leary a former NASA scientist criticizes the cost of the space shuttle program and is unconvinced of its economic justification. O'Leary expresses concern over NASA priorities and contends that the space transportation systems has "become the end rather than the means of space exploration."
Dr. James A. Van Allen, professor of physics and head of the Department of Physics and Astronomy at the University of Iowa notes that the "unmanned/automated/commandable spacecraft has provided at least 80 percent of the new scientific results and almost all the utilitarian applications of space technology."
Dr. George W. Rathgens from the Massachusetts Institute of Technology contends that the space shuttle should have low priority compared with other space programs and compared with other national needs.

U.S. General Accounting Office. Issues concerning the future operation of the Space Transportation System; study. [Washington] 1982. 26 p.
"GAO/MASAD-83-6, Dec. 28, 1982"
"The first priority of the Space Transportation System program now is to make the system fully operational and cost effective in providing routine access to space. This study addresses some of the major operational issues facing the National Aeronautics and Space Administration and the budgetary issues facing the Congress as this new era in space operations begins."

----- NASA report may overstate the economic benefits of research and development spending. Report of the Comptroller General of the United States. Washington, G.A.O., 1977. 53 p.
"PAD-78-18, Oct. 18, 1977"
GAO conducted an independent assessment of the NASA-commissioned report entitled "The Economic Impact of NASA R & D Spending," by Chase Econometrics, Inc. and concluded that the "Chase study does not prove convincingly that the benefits are as large as stated."

U.S. Office of Aeronautics and Space Technology. NASA space systems technology model. Washington, National Aeronautics and Space Administration, Office of Aeronautics and Space Technology, 1980. 3 v.
Contents.--Vol. 1: System/program descriptions and technology needs. --Vol. 2: Space technology trends and forecasts.--Vol. 3: Opportunity system/programs and technologies.

United States civilian space programs, 1958-1978; report prepared for the Subcommittee on Space Science and Applications of the Committee on Science and Technology, U.S. House of Representatives, 97th Congress, 1st session, by the Science Policy Research Division, Congressional Research Service, Library of Congress. Vol. 1. Washington, G.P.O., 1981. 1339 p.
"Serial D"
At head of title: Committee print.
Presents information on NASA and its relationship to U.S. space policy. Describes U.S. launch vehicles, manned space flight, the Space Transportation System, space sciences, and materials processing in space.

United States civilian space programs: volume II--applications satellites; report prepared for the Subcommittee on Space Science and Applications of the Committee on Science and Technology, U.S. House of Representatives, 98th Congress, 1st session, by the Science Policy Research Division, Congressional Research Service, Library of Congress. Washington, G.P.O., 1983. 381 p.
At head of title: Committee print.
"Serial--M"

Van, Jon. The marvelous machines we send into space. Chicago tribune magazine, Oct. 18, 1981: 44-45, 47, 52, 54.
Warns that costs may hinder further breakthroughs in space exploration.

B. Technology

Denver Research Institute. Space benefits: the secondary application of aerospace technology in other sectors of the economy. [Washington, National Aeronautics and Space Administration, 1981] 1 v. (various pagings)
Points to the economic benefits of the transfer of aerospace technology to other sectors of the U.S. economy. Summarizes "585 examples of beneficial use for NASA technology by public and private organizations."

Fitzgerald, Paul E., Jr., and Edward A. Gabris. The Space Shuttle focused-technology program: lessons learned. Astronautics & aeronautics, v. 21, Feb. 1983: 60-67, 72.
Technologies developed for the Space Shuttle will be incorporated in the space station.

Geostationary platform systems concept definition study. Vol. 1: Executive summary. Prepared by General Dynamics/Convair in cooperation with Communications Satellite Corp. Washington, U.S. National Aeronautics and Space Administration [available from NTIS] 1980. 72 p.
"NASA-CR-16147"
Concludes that geostationary platforms offer significant cost savings compared to individual satellites.

Kolm, Henry. An electromagnetic "slingshot" for space propulsion. Technology review, v. 79, June 1977: 60-66.
"Harnessed sunlight could produce electricity to drive powerful electromagnetic systems to launch ore from the moon and to propel asteroids and space stations."

Liquid-rocket propulsion technology. Astronautics & aeronautics, v. 21, Apr. 1983: 46-52, 54-56.
Contends that "the federal government should reinstate and firmly commit a long-range integrated program to develop liquid-rocket technology for the coming generation of space systems."

Spinoffs from the space program. Business week, no. 2606, Oct. 8, 1979: 26G-26H, 26K-26L, 26S.
Contents.--Next steps for mankind--the challenge of space, by A. Stevenson.--Spinoffs for solar energy, by P. Glaser.--The energy analysis program, by W. Marshall.--Technology transfer, by Z. Lansky.--The automated management information system, by G. Monroe and F. Helfand.--Insulation technology was ready for the space age, by C. Sulewski.--One giant leap of the industrial kind, by J. Adams.

U.S. Congress. House. Select Committee on Aging. Applications of space technology for the elderly and handicapped. Joint hearings, 96th Congress, 1st session. July 19-20, 1979. Washington, G.P.O., 1979. 168 p.
"Pub. no. 96-191"
"No. 38"

U.S. Congress. Senate. Committee on Commerce, Science, and Transportation. Subcommittee on Science, Technology, and Space. Symposium on the future of space science and space applications. Hearing, 95th Congress, 2nd session. Feb. 7, 1978. Washington, G.P.O., 1978. 109 p.
"Serial no. 95-58"

U.S. National Aeronautics and Space Administration. Spinoff 19--: an annual report. Washington, For sale by the G.P.O., 1974-
Volumes in this monographic series dated prior to 1974 were distributed by NTIS. Spinoff and the title Technology utilization program report are both used.
Describes technology developed through aerospace research and illustrates how NASA seeks to stimulate technology utilization to enhance productivity and quality of life.

----- Technology for large space systems: a special bibliography with indexes. Washington [Available from NTIS] 1981. 1 v. (various pagings)
"NASA SP-7046(05)"
Presents an annotated bibliography of documents "that define specific missions that will require large space structures to achieve their objectives. The methods of integrating advanced technology into system configurations and ascertaining the resulting capabilities is also addressed."

Ziska, Patrick J. Space: putting spinoffs to work. AFL-CIO American federationist, v. 85, Nov. 1978: 15-19.
Describes how space developed technology has been transferred to medicine, transportation, public safety, energy and pollution remedies, construction, communications, industrial and agricultural processes, sports, and recreation.

C. Industrialization

Baker, David. Cargo spaceships after Shuttle. Flight international, v. 115, Mar. 17, 1979: 836-838.
"Over the next few years the first reusable launcher, the Space Shuttle, will make it easier and cheaper to place payloads in orbit. Author looks at the Shuttle derivatives and new launchers that will be required when man begins building larger structures in space."

Baum, Rudy M. Firms eye growing role, with NASA, in commercializing space. Chemical & engineering news, v. 61, Oct. 17, 1983: 20-21, 27, 29.
Illustrates how businesses ranging from large aerospace firms to small entrepreneurs are becoming involved in the commercial uses of space.

Bittence, John C. Materials engineering in the sky. Materials engineering, v. 92, Oct. 1980: 34-41.
Describes the benefits of processing materials in outer space.

Bulloch, Chris. Materials processing in space: plenty of prophets, but what about profits? Interavia, v. 39, July 1984: 679-683.
Space offers envrionmental conditions, such as a high degree of vacuum and microgravity, that make processing of materials in space attractive, but there are economic risks involved.

Businesses grab piece of space. High technology, v. 1, Sept.-Oct. 1981: 14-18.
Describes the economic benefits of a reusable Space Shuttle. Payloads include communication satellites, a space telescope and an Automated Beam Builder to develop large structures in space.

Bylinsky, Gene. Space will be the next big construction site. Fortune, v. 99, Feb. 26, 1979: 63-65, 68.
Describes the plans, dreams, and problems associated with building large structures in space for communications and solar energy generation.

Commercialization of land and weather satellites; report prepared by Science Policy Research Division, Congressional Research Service, for the Subcommittee on Space Science and Applications and the Subcommittee on Natural resources, Agriculture Research and Environment, transmitted to the Committee on Science and Technology, U.S. House of Representatives, 98th Congress, 1st session. Washington, G.P.O., 1983. 365 p.
At head of title: Committee print.
"Serial H"

Commercialization of space. Aviation week & space technology, v. 120, June 25, 1984: 40-201.
This collection of articles covers such topics as economic policies to stimulate space commercialization, processing of materials and drugs in space, Landsat commericalization, and the viability of commercial space ventures.

Covington, Clarke, and Robert O. Piland. Space Operations Center: next goal for manned space flight? Astronautics and aeronautics, v. 18, Sept. 1980: 30-37.
Presents the concept of the space operations center, a permanent, manned facility in low Earth orbit, the mission of which would be the construction, assembly, and servicing of space systems and spacecraft.

Criswell, David, and Peter Marsh. Working on the Moon. New scientist, v. 92, Oct. 1, 1981: 30-33.
Sees the Moon as a natural site for factories and for mining materials.

Deudney, Daniel. Coming down to Earth: industry in space is a mirage of abundance. Across the Board, v. 19, Nov. 1982: 41-45.
"Although space manufacturing may become a modest industry some day, large-scale space industrialization is an unworkable attempt to escape from the problems of earth."

Dooling, Dave. The first space factories. Space world, v. S-3-219, Mar. 1982: 4-7, 32-33.
Reports on how future Space Shuttle missions will test the possibility of materials processing in low gravity.

----- Space factories in 1997. Spaceflight, v. 19, Oct. 10, 1977: 342-347; Oct. 25: 390-392.
Outlines results to date of materials processing experiments conducted in space under the near-vacuum conditions of microgravity. Describes the transportation vehicles and orbiting facilities envisioned for space processing applications in such areas as pharmaceuticals, ceramics, and electronics. Discusses the role industry might play in developing these applications.

For industry it's almost lift-off time. Business week, no. 2795, June 20, 1983: 62-65.
"A recent NASA-funded survey turned up 84 companies interested in doing some 244 experimental and commercial projects in orbit."

Gaffey, Michael J., and Thomas B. McCord. Mining outer space. Technology review, v. 79, June 1977: 50-59.
"Asteroids contain many of the minerals in short supply on earth. Detecting and recovering these minerals could be technically feasible and financially rewarding."

Grey, Jerry. Implications of the Shuttle: our business in space. Technology review, v. 84, Oct. 1981: 34-42, 44, 46.
Explores the commercial possibilities of the Space Shuttle. Calls for "imaginative public-private partnerships" to assure commercial success.

Hartmann, William K. Mines in the sky promise riches, a greener Earth. Smithsonian, v. 13, Sept. 1982: 71-76.
Foresees the mining of asteroids for metals needed on Earth.

Hosenball, S. Neil. The Space Shuttle in perspective. Journal of space law, v. 9, spring-fall 1981: 69-75.
Projects that "insurance to reduce the risk, incentives that NASA is willing to make available to U.S. industry, and the demonstrated willingness of industry and the financial community to invest their funds in space ventures make it clear . . . that the new Shuttle capabilities will exponentially increase commercial activities in space during the decade of the eighties."

Humphlett, Patricia E. Proposed sale of Landsat and the weather satellites. Congressional Research Service review, v. 4, Oct. 1983: 12-14.
"According to the Administration, the private sector is better equipped than the government to expand the Landsat data market; the private sector has the profit incentive and experience in marketing new products."

Kinnucan, Paul. Space business. High technology, v. 3, Oct. 1983: 42-45, 48-51.
Warns that a fear of high risks and budget cutbacks could impede commercialization of space.

Lepkowski, Wil. U.S. space policy ready for next big leap. Chemical & engineering news, v. 62, Feb. 1984: 9-16.
Looks at future commercialization of space technology including satellites, research and development in space and the future military uses of space by the U.S.

Lockerby, Robert W. Space-based manufacture. Monticello, Ill., Vance Bibliographies, 1984. 14 p. (Public administration series: biibliography P-1473)

Logsdon, John M. Space commercialization: how soon the payoffs? Futures, v. 16, Feb. 1984: 71-78.
Concludes "that commercialization is the wrong theme to be stressing now as the major justification for future space activities. Governments should take the actions required to remove barriers to private sector investment in space, but should also recognize that such actions are unlikely to lead to a flood of private investments."

McLearn, Donald C. Why drugs will be made in space. FDA consumer, v. 17, Nov. 1983: 19-23.
Describes the manufacturing technique called continuous flow electrophoresis which separates materials in solution by subjecting them to an electrical field and how this process, when used in space, can produce great quantities of materials such as enzymes, hormones and proteins for use in drugs.

O'Neill, Gerard K., Gerald Driggers, and Brian O'Leary. New routes to manufacturing in space. Astronautics & aeronautics, v. 18, Oct. 1980: 46-51.
Contend that "because of energy costs it makes sense to use lunar materials for the construction of products needed in space. Less than a twentieth of the energy to bring a ton to orbit from the Earth will bring it there from the Moon."

Reagan, Ronald. Remarks to National Aeronautics and Space Administration employees at the Goddard Space Flight Center, August 30, 1984. Weekly compilation of Presidential documents, v. 20, Sept. 3, 1984: 1197-1200.
In this speech the President discusses the commercial opportunities of space.

Remote sensing and the private sector: issues for discussion. Washington, U.S. Office of Technology Assessment, for sale by the Supt. of Docs., G.P.O., 1984. 141 p.
"OTA-TM-ISC-20"
"This technical memorandum, which was requested by the House Science and Technology Committee and the House Government Operations Committee, is designed to help Congress determine the appropriate requirements and conditions for private sector ownership of the U.S. land remote-sensing system." Examines the difficulty of transferring Government developed technology to the private sector.

Smith, Marcia S. The next decade in space: increased international economic competition. Congressional Research Service review, v. 3, July-Aug. 1982: 2-4, 25.
"As the U.S. space shuttle enters operational status later this year, it will face stiff competition in providing launch services to commercial and foreign customers from the European Space Agency's Ariane launch vehicle. Two other space activities long dominated by the United States also will face competition during the 1980s: France plans to launch a remote sensing satellite in 1984 which will compete with the U.S. Landsat satellites (other countries have similar plans), and Japan has the lead in developing certain new communications satellite technologies."

Should we make products on the Moon? Astronautics & aeronautics, v. 21, June 1983: 80-85.
"By the turn of the century, just a good development cycle away, commercial needs for large amounts of certain materials in Earth orbit may justify producing them on the Moon."

Space industrialization. Prepared by Science Applications, Inc. Huntsville, Ala., SAI [available from NTIS] 1978. 4 v.
"NASA-CR-150752--NASA-CR-150755." Prepared under NASA contract.
Projects benefits that could accrue to the U.S. from the investment of public and private resources in space industrialization.
Contents.--Vol. 1: An overview.--Vol. 2: Opportunities, markets, and programs.--Volume 3: World and domestic implications.--Volume 4: Appendices.

United Nations. Secretariat. Bibliography of the literature on activities that might be carried out using space platforms. New York, United Nations, 1980. 11 p. (United Nations. Document A/AC.105/265)

U.S. Congress. House. Committee on Government Operations. Legislation and National Security Subcommittee. International implications of proposed sale of Landsat satellite. Hearing, 98th Congress, 1st session. Sept. 28, 1983. Washington, G.P.O., 1984. 147 p.

U.S. Congress. House. Committee on Science and Technology. Commercial Space Launch Act; report to accompany H.R. 3942 including cost estimate of the Congressional Budget Office. Washington, G.P.O., 1984. 24 p. (Report, House, 98th Congress, 2nd session, no. 98-816)

U.S. Congress. House. Committee on Science and Technology. Subcommittee on Natural Resources, Agriculture Research and Environment. The commercialization of meteorological and land remote-sensing satellites. Hearings before the Subcommittee on Natural Resources, Agriculture Research and Environment and the Subcommittee on Space Science and Applications of the Committee on Science and Technology, U.S. House of Representatives, 98th Congress, 1st session. Washington, G.P.O., 1984. 1550 p.
"No. 53"
Hearings held Apr. 14-Nov. 9, 1983.

----- Land Remote-Sensing Commercialization Act of 1984--H.R. 4836 and H.R. 5155. Hearing before the Subcommittee on Natural Resources, Agriculture Research and Environment and the Subcommittee on Space Science and Applications of the Committee on Science and Technology, U.S. House of Representatives, 98th Congress, 2nd session. Mar. 6, 1984. Washington, G.P.O., 1984. 165 p.

U.S. Congress. House. Committee on Science and Technology. Subcommittee on Space Science and Applications. H.R. 7412: the Space Industrialization Act of 1980. Hearings, 96th Congress, 2nd session. June 11, 12, 1980. Washington, G.P.O., 1980. 88 p.
"No. 132"

----- Review of materials processing in space, 1983. Hearings, 98th Congress, 1st session. Sept. 14 and 15, 1983. Washington, G.P.O., 1984. 130 p.
"No. 42"

----- Space commercialization. Hearings, 98th Congress, 1st session. Washington, G.P.O., 1983. 385 p.
"No. 23"
Hearings held May 3-18, 1983.

----- Space industrialization. Hearing, 95th Congress, 1st session. Sept. 29, 1977. Washington, G.P.O., 1977. 204 p.
"No. 26"

----- The Space Industrialization Act of 1979. Hearings, 96th Congress, 1st session, on H.R. 2337. Washington, G.P.O., 1979. 288 p.
"No. 47"
Hearings held May 22-23; June 26-27, 1979.

U.S. Congress. Senate. Committee on Commerce, Science, and Transportation. Policy and legal issues involved in the commercialization of space; printed at the direction of Hon. Bob Packwood, Chairman. Washington, G.P.O., 1983. 52 p. (Print, Senate, 98th Congress, 1st session, committee print, S. Prt. 98-102)

U.S. Congress. Senate. Committee on Commerce, Science, and Transportation. Subcommittee on Science, Technology, and Space. Landsat commercialization. Hearing, 98th Congress, 2nd session, on S. 1855, S. 1861 and S. 2292. Mar. 22, 1984. Washington, G.P.O., 1984. 137 p. (Hearing, Senate, 98th Congress, 2nd session, S. Hrg. 98-747)
"Serial no. 98-69"

U.S. General Accounting Office. Effects on users of commercializing Landsat and the weather satellites; report by the Comptroller General of the United States. Feb. 24, 1984. Washington, G.A.O., 1984. 53 p.
"GAO/RCED-84-93"
"In March 1983, the administration proposed to transfer the National Oceanic and Atmospheric Administration's satellites--a land-observing satellite, called Landsat, and the weather satellites--to the private sector. This report discusses how these satellites are used worldwide and how their commercial operation might affect users."

VonPuttkamer, Jesco. The industrialization of space. Futurist, v. 13, June 1979: 192-199, 201.
"In the next few decades, commercial ventures in space could provide improved information services, unique space-derived products, and perhaps up to 20% of America's electrical energy. In the long run, the commercialization of space could also act as a stepping-stone to the large-scale colonization of space."

----- The next 25 years: industrialization of space: rationale for planning. Washington, U.S. National Aeronautics and Space Administration, 1976. 29 p.
"NASA-TM-79360"
Presented at Southeast 2001: The Next 25 Years, World Future Society Conference, Atlanta, November 12-13, 1976.
Foresees NASA's space industrialization program contributing to increased productivity on Earth, and providing new growth options for the future which would include permanent settlement of space and long range colonization and exploration.

Wilford, John Noble. NASA's next mission: big business in space. New York times magazine, Sept. 18, 1983: 47, 50, 83-84, 86-88, 90.
"As it celebrates its 25th year, the agency is under pressure to shift its emphasis away from exploration and toward commercial and military uses of outer space."

D. Space Station

Begley, Sharon. The next step into space. Newsweek, v. 103, Feb. 6, 1984: 83.
Points out that the proposed $81 billion space station may siphon off funds from other research projects, and that in order to give the space station enough to do other projects will be designed around it and will not fly until the space station is built.

Covault, Craig. NASA to shift focus with space station. Aviation week & space technology, v. 120, Mar. 14, 1983: 99-101.
Contends that the decision to develop a permanently manned space station "will change the character of the National Aeronautics and Space Administration from an agency that is geared to support highly structured, brief forays into space into a more broadly based space operations team capable of supporting multiple long-term manned space flight activities."

----- President orders start on space station. Aviation week & space technology, v. 120, Jan. 30, 1984: 16-19.
"The space station goal . . . is designed to maintain the development capabilities of the space shuttle and provide a focal point for a generation of new U.S. commercial enterprise."

----- Space station pivotal in NASA future. Aviation week & space technology, v. 118, Mar. 14, 1983: 83-85, 87, 89.
"National Aeronautics and Space Administration space station studies have matured to a point where findings and decisions made over the next eight months could affect the character of the agency for the next 10-20 years. NASA managers forecast station development would substantially change the character of U.S. space operations and the structure of NASA itself."

Culbertson, Philip E. Current NASA space station planning. Astronautics & aeronautics, v. 20, Sept. 1982: 36-43, 59.
"It embraces requirements from the science, commercial, international, and national security user communities--the goal being a versatile operational base providing a permanent presence in space."

Dooling, Dave. Starting a space station for the right reasons. Astronautics & aeronautics, v. 20, July-Aug. 1982: 14, 16, 18, 20.
A space station will become a reality only after there is a commitment to the development of projects that will require the use of such a station.

Grey, Jerry. Moving from dream to reality. Environment, v. 25, Nov. 1983: 7-13, 33-40.
"The development of the next generation of space stations, our beachheads in space, is inevitable, not so much for the purpose of political ascendancy that motivated Appollo but for sound economic, security, scientific, and sociological reasons."

Krieger, James. Commercial projects for space station taking root. Chemical & engineering news, v. 61, May 2, 1983: 37-38.
The consulting firm of Booz-Allen & Hamilton is compiling a list of companies that may be potential users of the manned space station. NASA has awarded Booz-Allen a contract to continue user development for the commercialization aspects of a manned space station.

Olstad, Walter B. Targeting space station technologies. Astronautics & aeronautics, v. 21, Mar. 1983: 28-68.
Outlines the technology that would be necessary to design and operate a long-life space station.

Sharp, Peter W. Evolutionary concepts for a space station and the relevant utilisation potential. Journal of the British Interplanetary Society, v. 37, Apr. 1984: 157-162.
Describes the concepts for a U.S. manned space station and a European unmanned station.

[Space station] Aerospace America, v. 22, Sept. 1984: 47-50, 52, 54-64, 66, 68-72, 74-78, 80.
Contents.--Space station: the next logical step, by J. Beggs.--The Space station program plan, by J. Hodge.--Space station: technology development, by R. Carlisle.--Space station design: innovation and compromise, by L. Powell, A. Cohen, and M. Craig.--Space station: the world connection, by R. Freitag, R. Lottman, and L. Wigbels.

Space station: policy, planning, and utilization; proceedings of the AIAA/NASA Symposium on the Space Station, Arlington, Virginia, July 18-20, 1983. New York, AIAA, 1983. 216 p.
This symposium, held by the American Institute of Aeronautics and Astronautics and by NASA, explored the designs, technology and potential applications of an Earth-orbiting space station. The operational feasibility of a space station was also considered.

Waldrop, M. Mitchell. NASA wants a space station. Science, v. 217, Sept. 10, 1982: 1018-1021.
Describes proposals for a permanent U.S. space station in low earth orbit which range from a multi-billion dollar space city to a low-budget platform.

----- Space city. Science 83, v. 4, Oct. 1983: 60-67.
While NASA awaits approval to begin construction, its scientists plan a cost effective and utilitarian space station.

U.S. Congress. House. Committee on Science and Technology. Subcommittee on Space Science and Applications. NASA's space station activities. Hearing, 98th Congress, 1st session. Aug. 2, 1983. Washington, G.P.O., 1983. 158 p.
"No. 37"

U.S. Congress. Senate. Committee on Commerce, Science, and Transportation. Subcommittee on Science, Technology, and Space. Civil space station. Hearing, 98th Congress, 1st session. Nov. 15, 1983. Washington, G.P.O., 1984. 90 p. (Hearing, Senate, 98th Congress, 1st session, S. Hrg. 98-523)
"Serial no. 98-48"

Walklet, Donn C. Alternative strategies for space station financing. Prepared by Terra-Mar [company]. Washington, U.S. National Aeronautics and Space Administration. 1983. 33 p.
"NASA-CR-175412"
"The attributes of the proposed space station program are oriented toward research activities and technologies which generate long term benefits for mankind. Unless such technologies are deemed of national interest and thus are government funded, they must stand on their own in the market place. Therefore, the objectives of a United States space station should be based on commercial criteria; otherwise, such a project attracts no long term funding. There is encouraging evidence that some potential space station activities should generate revenues from shuttle related projects within the decade. Materials processing concepts as well as remote sensing indicate substantial potential. Furthermore, the economics and thus the commercial feasibility of such projects will be improved by the operating efficiencies available with an ongoing space station program."

E. Living in Space

The 1975 NASA/Stanford study of space colonization. Space world, v. N-1-157, Jan. 1977: 32-34.
"The final report of the 1975 NASA/Stanford University Summer Study in engineering systems design recommends that the United States adopt a program to move toward the colonization of space."

Ahn, Chung-Hae. NASA's biomedical research program. Washington, National Aeronautics and Space Administration [available from NTIS] 1981. 221 p.
"NASA SP-452"
Describes the various biomedical research programs of NASA which have been "established to investigate the major physiological and psychological problems encountered by man when he undertakes spaceflight."

Anderson, Michele, John A. Rummel, and Stanley Deutsch. Biospex: biological space experiments: a compendium of life sciences experiments carried on U.S. spacecraft. Washington, U.S. National Aeronautics and Space Administration, 1979. 297 p.
"NASA Technical Memorandum 58217"
Presents information on 27 years of life science experiments on U.S. spacecraft from sounding rocket flights carrying primates (1948) to the Apollo Soyuz mission (1975). Each experiment includes information on principal investigators, flight on which experiment was performed, specimens, results and conclusions.

The Apollo-Soyuz test project; medical report. Arnauld E. Nicogossian, ed. Washington, National Aeronautics and Space Administration [for sale by NTIS] 1977. 129 p.
"NASA SP-411"
"This report details the results of the clinical aspects as well as the preflight and postflight research studies that were performed on the astronauts."

Assessment of zero gravity effects on space worker health and safety. [Prepared by the] Lyndon B. Johnson Space Center. Washington [Available from NTIS] 1980. 119 p.
"DOE/ER-10025-T1"
"DOE/NASA Satellite Power System Concept Development and Evaluation Program."
"One objective of the study is to assess the effects of all currently known deviations from normal of medical, physiological and biochemical parameters which appear to be due to zero gravity (zero-g) environment and to acceleration and deceleration to be experienced, as outlined in the reference SPS design, by space workers."

Bell, Larry. Designing a village in space. Futurist, v. 15, Oct. 1981: 36-41, 44-46.
Reports on a space village--Spacehab--being designed by researchers at the University of Houston. Spacehab, a station for a hundred workers, would be ferried into orbit, in parts, by the Space Shuttle.

Chaikin, Andrew. Sick in space. Science 84, v. 5, June 1984: 51-55.
Examines the problem of motor sickness during space flight and research efforts by NASA directed toward understanding and controlling astronaus[illegible]

Compton, W. David. Living and working in space: a history of Skylab, by David W. Compton and Charles D. Benson. Washington, Scientific and Technical Information Branch, National Aeronautics and Space Administration, For Sale by the Supt. of Docs, G.P.O., 1983. 449 p. (The NASA history series, NASA SP 4208)

The origins and evolution of the Skylab project are traced. Some of the topics covered in this work are the Skylab program organization, congressional and budgetary matters concerning Skylab, astronaut training, the science projects conducted on Skylab and their results, and the spacecraft's reentry in July 1979.

Cooper, Henry S. F., Jr. Life in a space station. New Yorker, v. 52, Aug. 30, 1976: 34-44, 49-53, 55-57, 59-66; Sept. 6: 34-40, 44-53, 56-70.

Reports on the experiences of the three crews who manned Skylab, their mental and physical problems, the experiments they conducted, their relations with ground control, and over-all assessment of the project.

Ehricke, Krafft A. The extraterrestrial imperative. Air University review, v. 29, Jan.-Feb. 1978: 2-20.

Asserts that man will extraterritorialize, that is, live in more than one world. The early stages to accomplish this are space industrialization and providing energy to benefit earth. Later man will colonize space.

----- The extraterrestrial imperative; part two: productive earth orbits--new partnership through pressures and promise. Journal of the British Interplanetary Society, v. 32, Nov. 1979: 410-418.

Exoindustrialization is seen as a means of improving the quality of life on Earth.

Fowles, Jib. The improbability of space colonies. Space world, v. 0-6-174, June 1978: 10-15.

Summarizes the optimistic approach toward space colonies taken by O'Neill in his High frontier. Discusses the necessity for minute regimentation of populations in space and the question of space industry profitability. Concludes that the tremendous costs will preclude space colonization.

Haise, Fred W., Jr. Hardhats in space. Space world, v. Q-5-197, May 1980: 6-13.

Conceptualizes the conditions for "astroworkers", those who will construct platforms, factories and observatories in outer space.

Hopkins, Mark M. A preliminary cost benefit analysis of space colonization. Journal of the British Interplanetary Society, v. 30, Aug. 1977: 289-300.

"This paper presents the economic results of the NASA/Ames-Stanford ASEE 1975 Summer Study of Space Colonization, as modified by subsequent work. The participants at the Summer Study only attempted to design a technically feasible system. . . . This paper is written, as is the Summer Study, in a style suitable for the layman who is knowledgeable about the space sciences but not about economics. As a result, the analysis has been kept simple, several elementary economic concepts are explained, and much of the material of interest to economists has been placed in appendices."

Joyce, Christopher. Space travel is no joyride. Psychology today, v. 18, May 1984: 30-32, 34-37.

NASA will build a laboratory at the Johnson Space Center to study space sickness. Solving problems associated with space sickness such as lethargy, lack of appetite, cold sweats and nausea is important now that the U.S. is planning a permanent space station.

Lockerby, Robert W. Space colonies: the next frontier. Monticello, Ill., Vance Bibliographies, 1980. 7 p. (Architecture series: bibliography A-313)

Overbye, Dennis, and Natalie Angier. Man in space: special report. Discover, v. 5, Apr. 1984: 13-18, 20-21, 24-27, 30-31.
Contents.--In the armchair of the gods, by D. Overbye.--Next stop: Solar Max.--Welcome to the cosmic motel, by N. Angier.--The last frontier.

Parkinson, Bob, and D. J. Sheppard. Small high-technology communities on the Moon. Spaceflight, v. 19, Feb. 1977: 42-51.
Presents "two contrasting articles on the theme of the Lunar Colony. The first by Dr. R. C. Parkinson takes as its theme 'small high technology communities on the Moon', the second by Dr. D. J. Sheppard considers 'an alternative technology for the Lunar Colony'."

Paterson, Erik T. Space settlements--the medical perspective. Journal of the British Interplanetary Society, v. 34, Oct. 1981: 429-434.
"Following an examination of the physiological responses to weightlessness, the likely implications are considered from the point of view of many diseases. Cardiac, respiratory, neurological, musculoskeletal, renal, reproductive, digestive, psychiatric and infectious diseases are shown to be probably strongly influenced by low, or zero, gravity. Some implications for rehabilitation are also discussed. It is concluded that major health benefits may be realised from the migration into space."

Rowes, Barbara. Housewives in space. Omni, v. 4, June 1982: 64, 66-67, 128.
Research conducted by NASA between 1977 and 1981 on 27 volunteers demonstrated that women are both physically and emotionally capable of withstanding the rigors of space travel.

Russell, Allan Melvin. Human societies in interplanetary space: toward a fructification of the utopian tradition. Technological forecasting and social change, v. 12, Dec. 1978: 353-364.
Author outlines a vision of future space colonies that he describes as utopian in the positive sense. He describes the social and political ramifications he expects to accompany the expansion of the human realm into space.

Salkeld, Robert. Toward men permanently in space. Astronautics & aeronautics, v. 17, Oct. 1979: 60-69.
Argues for an international Earth-orbital habitat for research and technology.

Santy, Patricia. The journey out and in: psychiatry and space exploration. American journal of psychiatry, v. 140, May 1983: 519-527.
Reviews the U.S. and U.S.S.R. research in aerospace medicine that is relevant to psychiatry and suggests ways to expand psychiatry's clinical and research usefulness in future space exploration efforts.

Smith, Alexander G. Constraints limiting the rate of human expansion into the galaxy. Journal of the British Interplanetary Society, v. 34, Sept. 1981: 363-366.
Theorizes that "human expansion into a largely lifeless galaxy will be constrained by ecological and engineering factors."

Space colonization. Journal of the British Interplanetary Society, v. 30, Aug. 1977: whole issue.
Partial contents.--On the realisation of projects: with special reference to O'Neill space colonies and the like, by A. Cleaver.--A preliminary cost analysis of space colonization, by M. Hopkins.--Two new propulsion systems for use in space colonization, by T. Heppenheimer.--Radiation protection for space colonies, by E. Hannah.--Raw materials for space manufacturing--a comparison of terrestrial practice and lunar availability.

Space settlements; a design study. Richard D. Johnson, ed. Washington, National Aeronautics and Space Administration, for sale by the Supt. of Docs., G.P.O., 1977. 185 p.
"NASA SP-413"
"This report, like the design itself, is intended to be as technologically complete and sound as it could be made in ten weeks, but it is also meant for a readership beyond that of the aerospace community. Because the idea of colonizing space has awakened strong public interest, the report is written to be understood by the educated public and specialists in other fields."

F. Planetary Exploration

Berry, Richard, and Robert Burnham. Voyager 2 at Saturn. Astronomy, v. 9, Nov. 1981: 6-30.
As Voyager 2 continues on to Uranus scientists are left with years of data to analyze from its encounter with Saturn. The author describes the wealth of information that was obtained on the atmosphere, ring system, and moons of Saturn.

Dagani, Ron. The planets: chemistry in exotic places. Chemical & engineering news, v. 59, Aug. 10, 1981: 25-36.
"Two decades of planetary exploration have greatly increased scientists' understanding of the makeup of the solar system; few new planetary missions, however, will be initiated in the 1980's."

Jaffe, Leonard D., and Harry N. Norton. A prelude to interstellar flight. Astronautics & aeronautics, v. 18, Jan. 1980: 38-44.
Examines the scientific benefits and technology requirements of an interstellar precursor mission, i.e., a mission beyond the planets but not as far as the stars.

Karl, Van. The planets or bust. Astronomy, v. 10, May 1982: 9-17.
Reports on the NASA Solar System Exploration Committee's attempts to resurrect a class of low cost missions to revive the planetary exploration program.

Moore, Jesse W. Effective planetary exploration at low cost. Astronautics & aeronautics, v. 20, Oct. 1982: 28-38, 52.
Reports on the work of the Solar System Exploration Committee which has examined ways to reduce costs for planetary mission.

Morrison, David. A program for planetary exploration, by David Morrison and Noel W. Hinners. Science, v. 220, May 6, 1983: 561-567.
"On the basis of a two-year study, the NASA Solar System Exploration Committee recommends a core program of planetary missions through the year 2000. By incorporating a number of cost-saving measures, an exciting program of planetary exploration can be achieved within a highly constrained NASA budget."

----- Voyage to Jupiter, by David Morrison and Jane Samz. Washington, U.S. National Aeronautics and Space Administration [for sale by the Supt. of Docs., G.P.O.] 1980. 199 p.
"NASA SP-439"
Describe the planet Jupiter and its moons. Profile the voyager missions to Jupiter and Saturn. Highlight the wealth of information on the Jovian system that was relayed to Earth by the Voyager satellites.

----- Voyages to Saturn. Washington, U.S. National Aeronautics and Space Administration [for sale by the Supt. of Docs., G.P.O.] 1982. 227 p.
"NASA SP-451"
Partial contents.--The ringed planet.--Pioneer to Saturn.--The Voyager mission.--Encounter with Saturn.--The last picture show.

Neugebauer, Marcia. Mariner Mark II and the exploration of the solar system. Science, v. 219, Feb. 4, 1983: 443-449.
Discusses the costs, scientific objectives and mission requirements for the Mariner Mark II, a spacecraft concept for the next generation of deep-space missions.

Overbye, Dennis. Back to the planets. Discover, v. 4, May 1983: 29-33.
A plan based on standardized spacecraft is being developed by NASA to save planetary exploration from budgetary attrition.

Stoker, Carol, and Christopher P. McKay. Mission to Mars: the case for a settlement. Technology review, v. 86, Nov.-Dec. 1983: 27-30, 35-37.
See a permanent settlement on Mars as a focus for developing space. Note that Mars is the planet most hospitable and similar to Earth.

Wilson, Andrew. Exploration of the solar system: the 1980's and beyond. Space education, v. 1, July 1981: 13-17.
Lists future space projects that NASA envisions over the next decade. Budgetary constraints may limit many missions.

G. Foreign Programs

Clark, P. S. The Chinese space programme. Journal of the British Interplanetary Society, v. 37, 1984: 195-206.
Reviews the development of the Chinese rocket and space programs from the end of World War II to the present.

Covault, Craig. Soviets developing 12-man space station. Aviation week & space technology, v. 112, June 16, 1980: 26-29.
Soviet development of a powerful thrust booster and a 220,000-lb. military/scientific space station will provide the USSR with a base to launch the first manned mission to Mars, as well as a strategic advantage over the U.S.

Dondi, G. Space activities in the 80's: the programs and the industry. Parts 1 and 2: survey of space programs (1975 to 1980); survey of the capabilities and experience of the European Space Agency. Paris, European Space Agency. 1981. 290 p.
"ESA-SP-1012-V-L-1"
Reviews programs of the European Space Agency and summarizes European industrial participation in space programs. Provides information on manufacturers in ESA countries involved in space industries.

Kinnucan, Paul. Rocket wars: how Europe may zap America. High technology, v. 3, Apr. 1983: 49-56.
"Europe's success in wooing space launch customers from NASA may embolden other competitors."

Lenorovitz, Jeffrey M. Arianespace markets launch service. Aviation week & space technology, v. 116, Jan. 11, 1982: 87, 90-91, 93, 95.
"Successful entry of Europe's Ariane launch vehicle into worldwide satellite launch services competition has been aided by the private Arianespace organization, which was formed to sell the system to prospective payload customers."

Oberg, James E. Made in the USSR: Kosmograd space colony number one? Space world, v. R-4-208, Apr. 1981: 4-13.
The author contends that "throughout the 1980s, Soviet space stations will grow in size, beyond the intermediate ones holding two to six crewmen. . . . Space experts are even predicting the appearance of 'space towns' with several thousand people, perhaps by the end of the century."

----- Soviet developments point for space operations center. Aeronautics & astronautics, v. 20, May 1982: 74-77.
Claims that "spacecraft systems already demonstrated will allow Soviet space engineers to create a permanently manned station in the near future."

[Salyut] Space world, v. p-4-184, Apr. 1979: 4-34.
Special issue on the Russian Salyut manned space program. The articles cover the history of the program, the international cooperative aspects, military Salyuts, and medical-biological aspects of the program.

Scott, William F., and Harriet Fast Scott. Space: are the Soviets ahead? Air Force magazine, v. 64, Mar. 1981: 84-89.
Recount the Soviet manned space program from Yuri Gagarin's flight in April, 1961 to the present.

Smith, Marcia S. Soviet space activities: impact on U.S. space policy. Space world, v. S-4-202, Apr. 1982: 19-21, 23, 34.
Reviews current Soviet space activities and considers how they might impact on U.S. space policy.

Soviet astronautics. Journal of the British Interplanetary Society, v. 36, Oct. 1983: whole issue.
Contents.--The evolution of the Soyuz programme, by P. Clark.--Salyut mission report, by N. Kidger.--Soviet space science, by J. Powell.--Soviet nuclear powered satellites, by R. Rees and C. Vick.--Soviet manned space flight hardware, by D. Haeseler.--The Soviet cosmonaut team, 1960-1971, by R. Hall.--The Soviet cosmonaut team, 1971-1983, by R. Hall.

Spacelab. Journal of the British Interplanetary Society, v. 29, Nov. 1976: whole issue.
Special issue on Spacelab, the European space station to be launched by the NASA Space Shuttle. Articles cover technical details, missions planning, and the nature of the cooperation necessary to design and launch this joint U.S.-European space program.

U.S. Central Intelligence Agency. National Foreign Assessment Center. Ariane: a European space launch vehicle. Washington [Available from NTIS] 1980. 13 p.
"SW80-10074, Oct. 1980"
Discusses characteristics and capabilities of the Ariane launch vehicle.

U.S. Congress. Office of Technology Assessment. Salyut: Soviet steps toward permanent human presence in space--a technical memorandum. Washington, OTA, for sale by the Supt. of Docs., G.P.O., 1983. 69 p.
"OTA-TM-STI-14, Dec. 1983"
Partial contents.--Early Soviet manned spaceflight.--Pre-Salyut Soyuz space flights.--Salyut space station characteristics.--Salyut activities.--Future directions.--Impact on foreign policy.

Winick, Lester E. Birth of the Russian space programme. Spaceflight, v. 20, May 1978: 162-173.
"This paper summarises the principal organisations, past and present, which have been concerned with the development of rocketry and cosmonautics" in the Soviet Union.

IV. MILITARIZATION OF SPACE

Anti-satellite weapons: arms control or arms race? Cambridge, Mass., Union of Concerned Scientists, 1983. 44 p.

Contents.--Current U.S. and Soviet space assets and ASAT systems.--A treaty limiting ASAT weapons.--The relationship between ASAT and ABM.--The ASAT threat with and without a treaty.--Verification and residual risks.--Comparison with the 1981 Soviet draft treaty.

The Arms control reporter: a chronicle of treaties, negotiations, proposals. 1982- Brookline, Mass., Institute for Defense & Disarmament Studies. monthly.

See section on Anti-Satellite Talks and space weapons update.

Bell, Trudy E. America's other space program. Space world, v. Q-4-196, Apr. 1980: 4-12.

Reports on developments in the military space program, which is seen as the "other" space program as distinct from NASA's efforts. Considers the investment in space exploration and defense to be too important to be curtailed by budgetary considerations.

Broad, William J. A fatal flaw in the concept of space war. Science, v. 215, Mar. 1982: 1372-1374.

The author states that "the exotic weaponry on which the Pentagon now spends more than $300 million a year would be rendered useless by a single nuclear blast in outer space."

Brown, Harold, Bernard Feld, Robert Jastrow, and Richard Garwin. The Space Shuttle and defense. New York, WNET/Thirteen, 1981. 8 p.

The MacNeil/Lehrer Report, Apr. 13, 1981.

Televised interview with "Harold Brown, former Defense Secretary; Bernard Feld, physicist; Robert Jastrow, NASA; Richard Garwin, physicist."

The military possibilities of the Space Shuttle are discussed in this interview.

Burbidge, E. Margaret. Adventure into space. Science, v. 221, July 29, 1983: 421-427.

Extols the benefits of space exploration but notes that "technological advances have given us the capability of extinguishing life on Earth in a nuclear holocaust."

Conference on the United Nations of the Next Decade, 17th, Cooperstown, N.Y., 1982. Maintaining peace in outer space. Muscatine, Iowa, Stanley Foundation, 1982. 48 p.

This conference discussed international cooperation for peaceful uses of space, preventing weaponization of space, and the future role of the United Nations in space management.

Giffen, Robert B. US space system survivability: strategic alternatives for the 1990s. Washington, National Defense University Press, 1982. 68 p. (National Defense University. Monograph series, no. 82-4)

Contents.--Why survivability?--The basics.--US and Soviet space systems: a satellite gap?--How to defeat a space system.--Meeting the threat.--Matching survivability to requirements.

Goedhuis, D. Some observations on the efforts to prevent a military escalation in outer space. Journal of space law, v. 10, spring 1982: 13-30.

Concludes that the chances of reaching a universal agreement on arms limitation in space will depend on a more widespread public consciousness of the need to reach such an agreement.

Graham, Daniel O. Defense and development on the high frontier. Imprimis, v. 11, June 1982: 1-6.
In this presentation, General Graham lists nine requirements the U.S. should meet to "reverse the ominous trends in the military balance if we adhere to current strategy and try to compete with the Soviets in piling up weapons of current technology."

----- High Frontier: a new national strategy. [Washington, High Frontier, 1982] 175 p.
Contents.--Strategy.--The military dimension.--Nonmilitary dimension.--Collateral actions.--Urgent requirements and costs.--Impacts.--Implementation.--Treaty considerations.

Hafner, Donald L. Averting a Brobdingnagian skeet shoot. International security, v. 5, winter 1980-1981: 41-60.
The author reviews the issues at stake and suggests what an effective anti-satellite (ASAT) agreement should contain.

Haggerty, James J. Military in space. Aerospace, v. 20, spring 1982: 1-9.
Highlights DOD research and development activities in space which are aimed at matching Soviet military capabilities in space.

Jastrow, Robert. The new Soviet arms buildup in space. New York times magazine, Oct. 3, 1982: 30-34, 89, 92-93, 98, 100.
"Russian leaders have long recognized the potential of space as a military arena. But only in recent years have they begun to develop a massive military space capability. A prominent space scientist warns that by developing satellites that can carry nuclear bombs, 'killer satellites' and other weapons, the Kremlin has forged ahead in the military use of space."

Kane, Francis X. Anti-satellite systems and U.S. options. Strategic review, v. 10, winter 1982: 56-64.
Reviews Soviet development of antisatellite systems (ASAT), examines Soviet ASAT objectives, and considers the implications for U.S. security.

Kaplan, Daniel. Lasers for missile defense. Bulletin of the atomic scientists, v. 39, May 1983: 5-8.
The author argues that the idea of using lasers in space to defeat a nuclear attack is flawed. To be effective, a sufficient number of lasers able to shoot down all Soviet missiles would need to be over the Soviet Union at all times. The author warns that the deployment of lasers could create instabilities in the strategic balance between the United States and the Soviet Union.

Karas, Thomas H. The new high ground: systems and weapons of space and war. New York, Simon and Schuster, 1983. 224 p.
The author calls for a national debate on the direction of our space policy before the U.S. becomes committed to a new arms race in space.

Koppes, Clayton R. The militarization of the American space program: an historical perspective. Virginia quarterly review, v. 60, no. 1, winter 1984: 1-20.
Warns that the 1980's may become the decade of American military exploitation of space. Criticizes the Reagan administration for shifting resources from the civilian and scientific side of the space program to the military.

Lacouture, John E. Space race. United States Naval Institute proceedings, v. 109, Feb. 1983: 51-57.
"The U.S. military has been slow to recognize the dangers of Soviet space supremacy to our national security. Although increasingly dependent on satellites for communications, surveillance, warning, weather, and navigation, development of military weapon systems in space has proceeded on a low-priority basis."

Lorenzini, Dino A. Space power doctrine. Air University review, v. 33, July-Aug. 1982: 16-21.
Recommends that the U.S. adopt a space power doctrine which is as comprehensive and unencumbered as possible. Describes elements of such a doctrine, and considers obstacles to its formulation.

Outer space--a new dimension of the arms race, edited by Bhupendra Jasani. London, Taylor & Francis; Cambridge, Mass., Distributed by Oelgeschlager, Gunn & Hain, 1982. 423 p.
Contains papers first presented at a symposium organized by the Stockholm International Peace Research Institute and held in Stockholm, November 17-20, 1981. This book is directed to the reader concerned about the extension of the arms race into outer space.

Putting America's defense into orbit: the most radical strategic policy change since World War II. Business week, no. 2795, June 20, 1983: 52-53, 56, 60.

Reagan, Ronald. National security: address to the nation, March 23, 1983. Weekly compilation of Presidential documents, v. 19, Mar. 28, 1983: 442-448.
Sometimes characterized as the "star wars" speech.

The Reality behind 'star warfare'. International currency review, v. 15, July 1983: 36-42.
"Expenditure on space warfare is going to exert additional open-ended pressures on the dollar financial system through opening a further dimension of headlong deficit-spending, which the collective ingenuity of the Federal bureaucy will be unable to offset or disguise."

Ritchie, David. Laser-rattling in outer space. Inquiry (San Francisco), v. 3, Sept. 1, 1980: 13-17.
The article deals with the arms race in space between the United States and the Soviet Union, and its implication for world peace due to the lack of an adequate treaty to limit space warfare.

Robinson, George S. Militarization and the Outer Space Treaty--time for a restatement of "space law". Astronautics & aeronautics, v. 16, Feb. 1978: 26-29.
"For outer space to be a sanctuary from the ever-grinding conflicts on Earth, resolve and teeth should be put into this multinational accord Outer Space Treaty."

Smith, Bruce A. Military space system applications increasing. Aviation week & space technology, v. 114, Mar. 9, 1981: 83-87.
Examines the increased utilization of space-based systems for military purposes, and views this as a strong trend during the 1980s.

Smith, Marcia S. The militarization of space and other international space issues. Congressional Research Service review, v. 3, Nov. 1982: 5-7, 18.
Reports on the Second United Nations Conference on the Exploration and Peaceful Uses of Outer Space, held in Vienna in August 1982.

----- Soviet space activities: impact on U.S. space policy. Space world, v. S-4-220, Apr. 1982: 19-21, 23, 34.
Reviews current Soviet space activities, and considers how they might impact on U.S. space policy.

Smith, R. Jeffrey. Administration resists demands for ASAT ban. Science, v. 222, Oct. 28, 1983: 394-396.
Presents Soviet and American attitudes toward a ban on antisatellites.

----- Antisatellite weapon sets dangerous course. Science, v. 222, Oct. 14, 1983: 140-142.
Warns that "if the real goal is to destroy the sensors that would warn the Soviets of a U.S. attack, the ASAT [antisatellite] has the potential to disrupt the present formulation of deterrence; continued ASAT development therefore seems likely to launch the country on a highly uncertain strategic course."

Soviet space operations emphasize strategic role. Defense electronics, v. 15, Oct. 1983: 140, 145-147.
"In the Soviets' quest for military supremacy, the U.S. is facing a frightening array of advanced satellites with a variety of military missions--and Russian spaceborne weapons platforms and a shuttlecraft are expected soon."

Space weapons. Bulletin of the atomic scientists, v. 40, May 1984: 15-15S.
Contents.--History and current debate, by R. Garwin and J. Pike.--Effect on strategic stability, by Y. Velikov.

Space weapons policy. Congressional digest, v. 63, Mar. 1984: 67-96.

Stares, Paul. Space and US national security. Journal of strategic studies, v. 6, Dec. 1983: 31-48.
"This article provides an overview of the evolution of the US military space program to illustrate the importance of outer space to US national security. Particular attention will be paid to the formulation of US space policy, the organization and management of the space program, the development of key satellite programs and the salient operational trends that have characterized the US militarization of space."

Stashevsky, Sergei, and Gennadi Stakh. Outer space must be free from weapons. Social sciences, v. 14, no. 2, 1983: 189-198.
"The rapid development of space technology has made the task of preventing the spread of the arms race to outer space an urgent and primary one."

Tsipis, Kosta, and Eric Raiten. Antisatellite weapons: the present danger. Technology review, v. 87, Aug.-Sept. 1984: 54-63.
Describes Soviet and American antisatellite development. Contends that "neither power could use the present generation of ASATS to prevent its opponent from launching a first strike or retaliating against cities and industry. This means that neither nation could alter the outcome of a nuclear attack or the general strategic balance." Calls for a treaty that would allow the present generation of ASATS but outlaw further developments.

U.S. Congress. House. Committee on Appropriations. Subcommittee on the Dept. of Defense. Department of Defense appropriations for 1984. Hearings, 98th Congress, 1st session. Washington, G.P.O., 1983. 818 p.
Part 8--Air Force procurement programs (except MX and B-1B); MX missile program; Command, control and communications programs; Role of military in space; Procurement policies and practices.

U.S. Congress. Office of Technology Assessment. Arms control in space: workshop proceedings. Washington, O.T.A., for sale by the Supt. of Docs., G.P.O., 1984. 64 p.
The workshop explored the relevance of anti-satellite (ASAT) weapons and tactics to arms control. Participants in the workshop stressed that "ASAT arms control cannot be a substitute for protecting and duplicating satellite functions."

----- Directed energy missile defense in space. Washington, O.T.A., for sale by the Supt. of Docs., G.P.O., 1984. 98 p.
Contents.--Booster characteristics.--Directed energy weapon concepts for boost phase intercept.--Other essential elements of a boost-phase intercept system.--Countermeasures to boost-phase intercept.--A word on "old" BMD and "new" BMD.--A hypothetical system architecture.--Defense goals I: the perfect defense.--Defensive goals II: less-than-perfect defense.--Principal judgments and observations.

U.S. Congress. Senate. Committee on Foreign Relations. Controlling space weapons. Hearings, 98th Congress, 1st session, on S. Res. 43 and S.J. Res. 28. Washington, G.P.O., 1983. 173 p.
Hearings held Apr. 14 and May 18, 1983.

U.S. General Accounting Office. U.S. antisatellite program needs a fresh look; report by the Comptroller General of the United States. Washington, G.A.O., 1983. 3 p.
"GAO/C-MASAD-83-5, Jan. 27, 1983"
"This is an unclassified digest furnished in lieu of a report containing security information."

U.S. President (1981- : Reagan) U.S. policy on ASAT Arms Control; communication from the President of the United States transmitting a report on his Administration's policy on arms control for antisatellite systems as required in the conference report for the Department of Defense Appropriations Act for fiscal year 1984. Washington, G.P.O., 1984. 24 p. (Document, House, 98th Congress, 2nd session, no. 98-197)

V. RESOURCE ALLOCATION AMONG COMPETING NATIONAL PRIORITIES

Brundage, Percival Flack. The Federal budget: recent trends and future opportunities. Price Waterhouse review, v. 15, autumn 1970: 6-21.
The former Director of the Budget makes some pertinent observations about the difficult national problems the OMB is currently dealing with--and those it will have to deal with in the years ahead.

The Dollars and logic of reordered priorities. Saturday review, v. 54, Oct. 9, 1971: 22-27, 54.
Contents.--Battling the balance sheet, by L. Ritter.--All the muscle at one-third the cost, by S. Melman.
Dr. Ritter's article appeared as "The political arithmetic of reordered national priorities" in the July 1971 Morgan Guaranty Survey.

Greenspan, Alan. "Fiscal constituencies"; they pose a mounting challenge to a free society. Barron's, v. 50, Oct. 12, 1970: 1, 8, 10, 12.
In a speech before the National Association of Business Economists, the author warns that "fiscal constituencies," i.e., individuals receiving payment in cash or in kind on a continuing basis under an ongoing Federal program, such as social security or Medicaid, pose a growing burden and a mounting challenge to a free society.

Humes, Kathryn H., and others. The future environment: U.S. and world trends. Washington, National Aeronautics and Space Administration 1975. 1 v. (various pagings)

"Aside from the Introduction, this volume is a collection of essays on some twenty issues that we have identified as reflecting a need for national policy-making and, a priori, having implications for spaceflight. Each essay contains a statement of the issue, a discussion of the dimensions of the problem, supporting information and data, and a list of potential policies or actions that might be taken."

Partial contents.--Non-renewable resources.--International conflict.--Population and food.--Environment.--Economics.--Individual and society.

Kamlet, Mark S., and David C. Mowery. The budgetary base in Federal resource allocation. American journal of political science, v. 24, Nov. 1980: 804-821.

"This paper examines the role of the budgetary base in the executive branch's federal budgetary process, focusing on the Office of Management and Budget (OMB). The analysis calls into question a number of standard assumptions in the theory of governmental budgetary decision-making. These include the definition of the base, its immutability over the planning cycle, the functions that it serves, and the extent to which it, as opposed to the increment, is the focus of attention of budgetary actors."

Lecht, Leonard A. Change in national priorities during the 1960s: their implications for 1980. [Washington] National Planning Association [c1972] 50 p. (National Planning Association. Report no. 132)

Says that if the trends of the 1960s continue, the U.S. may be overspending in defense and transportation and falling short of demands for increased welfare and urban expenditures by 1980.

Marshall, Ray. An effective alternative policy for the 1980's. USA today (magazine), v. 111, May 1983: 40-46.

"Our nation needs to target limited economic resources in a way that will assure healthy industrial development and full employment for the American economy of the 1980's and beyond."

Mayo, Robert P. The Federal experience viewed from the Executive Office of the President: an appraisal of our capabilities for meeting public needs. National tax journal, v. 25, Sept. 1972: 335-342.

Discusses two principal phases of the Federal Government resource allocation process: the year-long executive task of program examination, resource evaluation, and related tasks and the legislative task of examining, altering and authorizing specific programs, providing the obligational authority to incur expenditures and levying the taxes to pay for them.

National Tax Association Seminar on Financing the Seventies, Boston, 1972. Proceedings. National tax journal, v. 25, Sept. 1972: whole issue.

Contents.--Fiscal decision making: spending requirements and executive choice among competing expenditure categories--who gets what, when, and how much.--Legislative decision making: developing organization and procedures for high quality tax systems.--Possible new revenue sources for the seventies.--Developing changes in existing revenue sources.

National Urban Coalition. Counterbudget; a blueprint for changing national priorities 1971-1976. New York, Praeger [c1971] 348 p.

Okun, Arthur M. Equality and efficiency: the big tradeoff. Washington, Brookings Institution [c1975] 124 p.

Explores the conflicts that arise when society's desire to reduce inequality would impair economic efficiency, confronting policymakers with "the big tradeoff."

Public claims on U.S. output: Federal budget options in the last half of the seventies. Washington, American Enterprise Institute for Public Policy Research [1973] 218 p. (American Enterprise Institute for Public Policy Research. Domestic affairs studies, no. 18)

Study finds that the 1974 Federal budget program, if implemented, meets the administration's stated goal of a virtual balance between expenditures and "full employment" receipts in calendar year 1975 and would provide surpluses thereafter, rising from $9 billion in 1976 to $57 billion in 1980. The authors examine the rationale for existing programs and develop, in varying degrees of detail, the costs of other alternatives, asking such questions as: how well are existing programs in defense, agriculture, science, technology and industry, housing, education, manpower, health, and income security meeting their stated goals? What viable options exist to present (or proposed) programs, including curtailments or terminations?

Rolan, Robert G. Must we choose between men in space and mankind on Earth. Bioscience, v. 20, July 15, 1970: 797-806.

"This paper is an attempt, to determine whether the goals of manned space flight and environmental improvement on Earth are really competitive and mutually exclusive or are, in fact, similar in many major points."

Russell, Bertrand. Let's stay off the Moon. Wall Street journal, July 16, 1969: 16.

Lord Russell questions whether the conquest of the moon or space can "ameliorate our human lot."

"There are some who seem to imagine that space travel, will, of itself, lead to some cure for our terrestrial troubles. I cannot see any reason to think this. Europe had troubles before the Western Hemisphere was discovered. After it was discovered, the wars to which the old world was accustomed were transplanted to the 'new world.' Unless we amend our ways, the same thing will happen if we extend our silly empires into outer space."

Sederberg, Peter C., and Marcia Whicker Taylor. The political economy of no-growth. Policy studies journal, v. 9, spring 1981: 735-755.

"Problems of scarcity generate critical political issues as advanced industrial societies shift away from growth-oriented economies. This analysis recommends substituting more abundant political resources for scarce economic ones. Appropriate scenarios resulting from these substitution patterns are subjected to speculative analysis."

Setting national priorities: the 1984 budget. Washington, Brookings Institution, 1983. 248 p.

Contents.--Introduction and summary, by J. Pechman.--The budget and the economy, by J. Pechman.--The defense budget, by W. Kaufman.--Social security, by A. Munnell.--Medical care, by L. Russell.--Jobs and training, by D. Saks.--Tax policy, by H. Galper.--The choices ahead, by H. Aaron.--Appendix A. Estimates of the structural deficit, by J. Pechman.--Appendix B. Federal credit activities, by E. Rhyne.--Appendix C. Tax expenditures, by J. Scholz.

This report, analyzing the Federal budget, is the latest in a series dating back to 1970.

Space Shuttle: NASA versus domestic priorities. Congressional quarterly weekly report, v. 30, Feb. 26, 1972: 435-439.

Strengthening the Federal budget process: a requirement for effective fiscal control. Washington, Committee for Economic Development, Research and Policy Committee, 1983. 106 p.

Contents.--Introduction and summary of recommendations.--Budget concepts: improving the information base for budget decisions.--Budget processes: strengthening procedures for budget decisions and enforcement.--Next steps for improving the budget process.--Memoranda of comment, reservation, or dissent.

U.S. Congress. Joint Economic Committee. Subcommittee on Economy in Government. Changing national priorities. Hearings, 91st Congress, 2nd session. Washington, G.P.O., 1970. 2 v. (741 p.)
Hearings held June 1-18, 1970.

U.S. Domestic Council. White House public forums on domestic policy, 1975; report to the President. [Washington, 1976] 765 p.
Summarizes findings of the six forums held in Denver, Tampa, Fla., Austin, Tex., Philadelphia, Indianapolis, and Los Angeles during Oct.-Dec. 1975. Focus of the discussion is on economic growth, resource development, social policy and community building.

RESEARCH GUIDE

SPACE EXPLORATION AND DEVELOPMENT:

INTRODUCTION

This research guide identifies research tools and sources of information about astronautics & space sciences. The guide is divided into two parts. The first part describes basic research sources and lists the search terms which can be used when examining these tools. The second part describes specialized space reference sources.

Users of this guide may be able to locate these materials at a nearby public, research, or depository library. The Congressional Research Service cannot perform searches of the commercial online data bases or provide copies of the items listed.

BOOKS

Library of Congress subject headings are used in many library catalogs nationwide. This partial listing of subject headings may be used to identify books in the Library of Congress catalog and other library catalogs on space issues.

SEARCH TERMS:
- Artificial satellites
- Astronautics
- Astronautics and civilization
- Budget--United States
- Manned space flight
- Outer space--Exploration
- Space law
- Space stations
- United States--Economic policy
- United States--Social policy

The search terms listed above may also be used for online commercial access to Library of Congress bibliographic records.

JOURNAL ARTICLES

Citations to journal articles and other materials about space can be found in a number of printed indexes and online bibliographic data bases. The materials covered by the printed indexes are briefly described here and the appropriate search terms are also listed.

Online bibliographic data bases enable the researcher to locate citations to journal articles and other materials quickly by using a computer terminal to search a machine-readable file. Online data bases allow the researcher to combine search terms in ways that are impossible in a printed index or library catalog and to simultaneously search material that would be contained in printed index volumes covering several years. The availability of various indexes online is indicated in the description of the tools.

> MAGAZINE INDEX

Magazine Index provides citations to materials in over 370 popular magazines, focusing on coverage of current affairs, leisure time activities, arts, sports, and science and technology. The Index is available online commercially.

SEARCH TERMS:
- Artificial satellites
- Astronautical research
- Astronautics
- Astronautics and state
- Budget--planning
- Space colonies
- Space flight
- Space sciences
- Space shuttles
- Space weapons

> PUBLIC AFFAIRS INFORMATION SERVICE BULLETIN (PAIS)

PAIS is a subject index of books, pamphlets, government publications, reports of public and private agencies, and periodical articles relating to economic and social conditions, public administration, and international relations. PAIS is available online commercially.

SEARCH TERMS:
- Budget, Government
- Satellites, Artificial
- Space flight
- Space, outer
- Space research
- Space stations
- Space technology
- United States--Economic policy
- United States--Social policy

> READERS' GUIDE TO PERIODICAL LITERATURE

The Readers' Guide is an author/subject index to periodicals of general interest published in the U.S.

SEARCH TERMS:
- Artificial satellites
- Budget
- Space colonies
- Space flight
- Space research

> BUSINESS PERIODICALS INDEX

Business Periodicals Index is a subject index to articles appearing in English language business periodicals. The Index is issued monthly and cumulated quarterly and annually.

SEARCH TERMS:
- Astronautics
- Budget
- Program budgeting
- Satellites, Artificial
- Space flight
- Space research
- Space vehicles

LEGISLATIVE INFORMATION

Congressional activities on space issues may be monitored by searching the following printed publications.

> CONGRESSIONAL RECORD

The Congressional Record provides an edited transcript of the activities on the floor of the House and the Senate. It is published each day Congress is in session. Subject and name indexes are published biweekly and cumulated annually.

SEARCH TERMS:
- Budget of the United States
- National Aeronautics and Space Administration
- Space policy
- Space program
- Space sciences

> CONGRESSIONAL RECORD ABSTRACT FILES

The Congressional Record Abstract Files (CR) contain abstracts of material in the Congressional Record from the 94th Congress, 2d session to the present. A typical entry includes the abstract, bill numbers, indexing terms, and page number references to the full text of the Congressional Record, and the date of the Record. These files have full-text retrieval capabilities, making it possible for the researcher to formulate his own search terms in addition to using terms which are part of a controlled searching vocabulary. The CR files are commercially available to the general public.

SEARCH TERMS:
Artificial satellites
Astronautics
Space law
Space policy
Space sciences

Bills and Resolutions

> CONGRESSIONAL QUARTERLY WEEKLY REPORT

Congressional Quarterly Weekly Report provides current information on congressional activities, the progress of major bills, and background information on major policy issues. Important recent articles are indexed on the back cover of each issue. Consult this index under the heading "Budget" and "Defense." A quarterly and an annual index are also issued. Congressional Quarterly also publishes an annual publication which cumulates material appearing in the weekly reports during a year. This publication is entitled CQ Almanac. Congressional Quarterly Weekly Report is available online through the NEXIS library.

SEARCH TERMS:
Appropriations
Budget
Defense
Foreign policy

> CONGRESSIONAL QUARTERLY ALMANAC

See description above.

SEARCH TERMS:
Budget, U.S.
Missiles [for ASAT]
National Aeronautics and Space Administration
Satellites
Space and space programs
Space policy

> NATIONAL JOURNAL

National Journal provides information on important executive branch and congressional actions. In addition to the annual index, the back cover of each issue also contains a brief index to recent articles. Consult this index under the headings "Defense" and "Budget."

SEARCH TERMS:
Economy, domestic
National Aeronautics and Space Administration

> DIGEST OF PUBLIC GENERAL BILLS AND RESOLUTIONS

The Digest summarizes the essential features of public bills and resolutions and changes made in them during the legislative process. The Digest is published during each session of Congress in two cumulative issues and a final issue at the conclusion subject indexes.

SEARCH TERMS:
Economic policies and conditions
Public finance and budgets
Space
- Artificial satellites
- Communication satellites
- Space policy

> MAJOR LEGISLATION OF THE CONGRESS (MLC)

The MLC provides summaries of selected major legislation arranged by subject. It includes background on the issues and information on the content and status of major bills affecting that issue. The publication may be examined at a Government depository library or purchased from the Government Printing Office. Search under the headings "Space issues" in the table of contents.

SEARCH TERMS:
Budget and government spending
National defense and security
Science and technology

Congressional Publications

> CIS INDEX (Index to the Publications of the United States Congress)

The CIS Index, produced by the Congressional Information Service, abstracts all congressional publications with the exception of the Congressional Record. The Index is published monthly and cumulated quarterly and annually. Each issue of the Index is divided into index and abstract portions. The Index is commercially available online.

SEARCH TERMS:
Astronautics
Budget of the U.S.
Communication satellites
International cooperation in astronautics
Space commercialization
Space programs
Space research
Space shuttle
Space stations
Space weapons

Copies of recently issued hearings and committee prints should be requested directly from the issuing committee. Congressional hearings and committee prints may also be found in the collections of Government depository libraries.

GOVERNMENT PUBLICATIONS

> MONTHLY CATALOG OF UNITED STATES GOVERNMENT PUBLICATIONS

The Monthly Catalog lists documents issued by all branches of the Federal Government. The catalog has monthly, semiannual, and annual indexes arranged by author, title, subject, keywords, and series/report title. The Monthly Catalog is commercially available online.

SEARCH TERMS:
Headings starting with the word Astronautics
Headings starting with the words Artificial satellites
Headings starting with the word Budget
Headings starting with the word Space

> WEEKLY COMPILATION OF PRESIDENTIAL DOCUMENTS

The Weekly Compilation of Presidential Documents contains statements, messages, and other presidential materials released by the White House during the preceding week. The Weekly Compilation has weekly, quarterly, and annual indexes.

SEARCH TERMS:
Arms and munitions
- Outer-space weapons
Budget, Federal
Space program

NEWSPAPER ARTICLES

The following indexes may be used to locate newspaper articles on space issues.

> NEW YORK TIMES INDEX

The New York Times Index provides extensive abstracts for articles appearing in the New York Times.

SEARCH TERMS:
Astronautics
Budgets and budgeting
Satellites
Space
Space weapons
United States--Finances--Budgets and budgeting

> BELL & HOWELL NEWSPAPER INDEXES

The Bell & Howell Newspaper Indexes list articles appearing in the Chicago Tribune, Chicago Sun-Times, Denver Post, Detroit News, Houston Post, Los Angeles Times, New Orleans Times-Picayune, San Francisco Chronicle, and Washington Post.

SEARCH TERMS:
Artificial satellites
Space (Outer)
Space exploration
Space stations
Space vehicles
United States Govt.--Budget

> OFFICIAL WASHINGTON POST INDEX

The Index provides access to all substantial newsworthy items in this paper.

SEARCH TERMS:
Artificial satellites
Astronautics
Budget--United States
Reusable space vehicles
Space ships
Space stations

> NATIONAL NEWSPAPER INDEX

National Newspaper Index, produced by Information Access Corporation, is available online as part of the Lockheed Dialog system, and provides front-page to back-page indexing on current affairs topics in the Christian Science Monitor, New York Times, Wall Street Journal, Los Angeles Times, and the Washington Post.

> NEXIS

The NEXIS online library provides access to wire service articles from the Associated Press, United Press International, and Reuters, articles from the Washington Post and journal articles. The journals indexed include Newsweek and U.S. News & World Report. In addition to providing citations and abstracts of the materials included in the data base, NEXIS makes the full text of the articles available online. NEXIS also provides access to the New York Times Information Bank, which is a current affairs data base containing citations to the New York Times and over sixty newspapers and journals.

> NEWSSEARCH

Newssearch is the daily update of Magazine Index, National Newspaper Index, and Legal Resources Index in the Lockheed Dialog system. It provides front-page to back-page indexing of the Christian Science Monitor, Wall Street Journal, and New York Times, as well as popular magazines, law journals, and legal newspapers.

ADDITIONAL SOURCES OF SPACE INFORMATION

INDEXES AND BIBLIOGRAPHIC DATA BASES

Citations to journal articles and other materials about space issues will be found in a number of printed indexes and online bibliographic data bases.

Aerospace Daily On-Line is a commercial database available from Ziff-Davis Publishing Company, 1156 15th St. N.W., Washington, D.C. 20005. It contains the same information as Aerospace Daily and can be used to search for defense and space programs, budgets, and technical and industrial trends. The system has two sections: Aerospace Daily abstract service which has daily on-line delivery of 2-3 line abstracts and full text call-up capabilities; and Aerospace Intelligence Retrieval which includes Aerospace Daily Historical Service, Defense Budget Scan, NASA Budgetscan and Defense Electronics Magazine.

Applied Science & Technology Index is a subject index to articles appearing in science and engineering journals. The Index is issued monthly and cumulated quarterly and annually.

Arms Control Reporter is a published monthly by the Institute for Defense and Disarmament Studies. The Reporter presents the status, analysis and chronology on treaty negotiations on such topics as Anti-ballistic Missile Treaty, SALT II, chemical weapons, antisatellite talks and nuclear non-proliferation. The chronology pages give day-to-day coverage of talks compiled from news services around the world. The parties, agendas and positions of all sides involved in the talks are included in the status pages. Text pages reproduce the essential documents, communiques and speeches. In the analysis pages are outside critiques of the talks assembled from other publications. This section highlights how problems existing in treaty negotiations might be resolved.

International Aerospace Abstracts is published semimonthly by the American Institute of Aeronautics and Astronautics. IAA covers published literature in periodicals and books; meeting papers and conference proceedings issued by professional and academic organizations; and translations of journals and articles in aeronautics and space science and technology. Indexes are cumulated semiannually and annually.

NTIS (National Technical Information Service) database is available commercially online. NTIS consists of government sponsored research, development, and engineering prepared By Federal agencies, their contractors or grantees. Through this system, unclassified, publicly available reports are made available for sale from such agencies as NASA, DOE, DDC, HHS, HUD, DOT, and the Department of Commerce. The database includes materials from both the hard and soft sciences, including material on technological applications, business procedures and regulatory matters.

Science Citation Index is published quarterly with an annual cumulation. The Index provides access to related articles by indicating sources in which a known article by a given author has been cited. This index is available commercially online as Scisearch.

Scientific and Technical Aerospace Reports (STAR) is published by NASA on the 8th and 23rd of every month. Cumulative index volumes are published annually. STAR announces current publications on all aspects of aeronautics and space research and development, supporting basic and applied research, and applications. Included in STAR are NASA contractor, and NASA grantee reports, reports by U.S. Government agencies, domestic and foreign institutions, NASA owned patents and patent applications, and dissertations and theses.

REFERENCE BOOKS

The Illustrated encyclopedia of Space technology: a comprehensive history of space exploration. New York, Harmony Books, 1981. 289 p.

Traces the history of the conquest of space, and considers such concepts as space colonies, factories in space, satellite solar power stations and bases on the Moon. Contains information on Soviet and Chinese launch vehicles.

The McGraw-Hill encyclopedia of space. New York, McGraw-Hill, 1968. 381 p.

This work is a translation of La grande aventure de l'espace (Paris, 1967). Topical sections deal with rockets, artificial satellites, space navigation, man in space, life in the universe, astronomy-astrophysics, and astronautics in the world today.

The RAE table of earth satellites 1957-1982, 2nd edition, compiled at the Royal Aircraft Establishment, Farnborough, Hants, England. London, MacMillan Publishers, 1983. 753 p.

The Table is a chronological list of the 2,389 launches of satellites and space vehicles between 1975 and the end of 1982, giving the name and international designation of each satellite and its associated rockets, date of launch, lifetime, mass, shape, dimensions and at least one set of orbital parameters.

CRS-8

A Record of NASA space missions since 1958. Compiled by Alfred Rosenthal for the Goddard Space Flight Center. Washington, NASA Goddard Space Flight, 1982. 879 p.

Describes major NASA missions during the period of 1958 to 1981. Included are those in support of the U.S. space program, as well as projects conducted in cooperation with private industry and in association with foreign nations. The material is arranged chronologically.

ORGANIZATIONS

The following organizations were selected from the Encyclopedia of Associations and the Washington Information Directory, 1982-83 as possible sources of information on space issues. The descriptions of the groups' activities are taken from these sources.

Aerospace Industries Association of America
1725 DeSales St., N.W.
Washington, D.C. 20036
(202) 429-4600

This is an association of U.S. companies engaged in research, development, and manufacture of aerospace systems, including manned and unmanned aircraft; missiles; launch vehicles and spacecraft; and propulsion, guidance, and control units. Maintains a library which is open to the public.

American Institute of Aeronautics and Astronautics (AIAA)
1633 Broadway
New York, N.Y. 10019
(212) 581-4300

Includes scientists and engineers in the fields of aeronautics and astronautics. Conducts an interchange of technical information through its publications and technical meetings. Its Technical Information Service provides library and abstracting services including the semimonthly International Aerospace Abstracts.

American Astronautical Society (AAS)
6060 Duke St.
Alexander, Va. 22304
(703) 751-7721

Promotes and supports scientific research related to the development of astronautical sciences. Conducts an annual Goddard Memorial and Military Space Symposium.

Aviation/Space Writers Association
1725 K St., N.W.
Washington, D.C. 20006
(202) 296-4394

Provides information to members on the aviation and space industries; sponsors an annual news conference and regional meetings.

National Space Club (NSC)
655 15th St., N.W., No. 300
Washington, D.C. 20005
(202) 639-4210

This nontechnical organization of individuals and companies affiliated with the missile and space fields seeks to maintain U.S. space leadership, and stimulate the advancement of peaceful and military applications of space flight and related technologies. Its membership is drawn from government, industry, the military, and the press.

National Space Institute (NSI)
600 Mayland Ave., S.W.
West Wing, Suite 203
Washington, D.C. 20024
(202) 484-1111

Seeks to provide a forum for public participation to help ensure that the space program is responsive to public priorities. Provides information on NASA activities and promotes the space program nationally. Monitors legislation and regulations that affect the space program.

SELECTED PERIODICALS

The following periodicals frequently contain articles on space policy and protection issues:

Aerospace (Quarterly)
Aerospace Daily (5 times a week)
(a news service for the entire aerospace industry)
Air University Review (bimonthly)
Astronautics & aeronautics (monthly)
Aviation week & space technology (weekly)
Journal of space law (semi-annual)
Journal of the British Interplantary Society (monthly)
Spaceflight (monthly)
Science (weekly)

UNITED STATES GOVERNMENT PRINTING OFFICE
SUPERINTENDENT OF DOCUMENTS
WASHINGTON, D.C. 20402

SB-176
August 10, 1984

PUBLICATIONS RELATING TO THE 1984-85 COLLEGE DEBATE TOPIC

Resolved: That the United States Federal Government Should Significantly Increase the Exploration and/or Development of Space Beyond the Earth's Mesosphere.

NASA Aeronautics. Rev. 1980. 27 p. il.
NAS 1.2:Ae 8/5 S/N 033-000-00796-5 2.50

NASA Grant and Cooperative Agreement Handbook (NHB 5800.1A). *This Handbook prescribes policies and regulations relating to the award and administration of NASA research grants. It represents a significant NASA step in the publication and dissemination of NASA policies and procedures. Subscription service consists of a basic manual, changes and procurement grant directives issued irregularly for an indeterminate period.* October 1983. Subscription price: Domestic - $23.00; Foreign - $28.75. [NGH] (File Code 1X)
NAS 1.18:G 76/2/983 S/N 033-000-81001-6

NASA 1958-1983: Remembered Images. *A pictorial history of the National Aeronautics and Space Administration. Topics covered include the Space Shuttle, the Apollo Program, Apollo-Soyus, Voyager and Mariner spacecraft and the Spacelab.* 1983. 136 p. il.
NAS 1.19:200 S/N 033-000-00901-1 22.00

National Aeronautics and Space Administration, Twenty-Fifth Anniversary: 1958-1983. *A pictorial chronology of the National Aeronautics and Space Administration, beginning with the launching of Explorer One and continuing through the flight of Space Shuttle Challenger. This publication may be purchased at a special price of $24.00 per 100 copies when mailed to one address.* 1983. 13 p. il.
NAS 1.2:An 7 S/N 033-000-00879-1 2.75

National Space Program: From the Fifties Into the Eighties. *Traces the history of the National Space program from the 1950s to the present. Civilian and unclassified military space policies are analyzed. Programs of the National Aeronautics and Space Administration as well as the Department of Defense are included.* 1983. 130 p. il.
D 5.409:83-6 S/N 008-020-00959-8 4.25

Next Step: Large Space Structures. *Describes large antennas, space platforms, and other potential large space structures made possible by the Space Shuttle's capabilities.* 1982. 8 p. il.
NAS 1.20:NF-129 S/N 033-000-00853-8 2.00

New Dimension in Space Experimentation. *Explains in detail the uses of the Long Duration Exposure Facility (LDEF). There are 53 scientific and technological experiments inside the LDEF. It will use about 50% of the Space Shuttle's payload capacity and will be launched and retrieved by the Space Shuttle.* 1984. 12 p. il. NAS 1.20:NF-140 S/N 033-000-00914-3 $ 1.00

New Horizons. *Outlines the astronautical and terrestrial benefits that have resulted from various NASA programs and discusses the promise of ongoing and planned projects.* Rev. 1977. 40 p. il. NAS 1.19:117/2 S/N 033-000-00697-7 2.75

NIMBUS Six Randon Access Measurement System Applications Experiments. *Traces the historical development of the NIMBUS 6 satellite from its early oceanographic tracking missions, through its polar expeditions and discusses future technological developments.* 1982. 102 p. il. NAS 1.21:457 S/N 033-000-00867-8 5.50

Outlook for Space: Report to the NASA Administrator by the Outlook for Space Study Group. 1976. 385 p. il. NAS 1.21:386 S/N 033-000-00640-3 8.00

Planetary Exploration Through the Year 2000: Core Program. *Topics include recommended program strategy, the era of spacecraft exploration, scientific strategy for planetary exploration, core program implementation, and missions for a core program.* 1983. 167 p. il. NAS 1.2:Ex 7/2 S/N 033-000-00882-1 7.00

Executive Summary to the above. 1983. 28 p. il. NAS 1.2:Ex 7/2/exec.sum. S/N 033-000-00871-6 5.50

Possibility of Intelligent Life Elsewhere in the Universe, Report (Revised October 1977). Rev. 1977. 126 p. il. Y 4.Sci 2:95/0 S/N 052-070-04332-6 4.75

President's Private Sector Survey on Cost Control: Report on Research and Development. *Contains major recommendations which could result in cost savings for Federal research laboratories; administration of research grants to universities; NASA cost reporting; and in other aspects of Federal research and development.* 1984. 156 p. Pr 40.8:C 82/R 31 S/N 003-000-00625-5 4.50

Project Orion: A Design Study of a System for Detecting Extrasolar Planets. 1980. 204 p. il. NAS 1.21:436 S/N 033-000-00790-6 7.00

Proving the Space Transportation System: The Orbital Flight Test Program. *Describes a test program designed to verify the Space Shuttle Columbia's performance under real spaceflight conditions, and to establish its readiness for operational duty. Tests conducted included experiments with a mechanical arm, launching and landing systems, and various computer simulations.* 1983. 19 p. il. NAS 1.20:NF-137/83 S/N 033-000-00884-8 2.50

SALYUT: Soviet Steps Toward Permanent Human Presence in Space: A Technical Memorandum. 1983. 76 p. il., 8 photos in pocket. Y 3.T 22/2:11 Sa 3 S/N 052-003-00937-4 4.50

Scientific and Technical Aerospace Reports (STAR). (Semimonthly.) *This subscription announces abstracts, and indexes reports issued by the National Aeronautics and Space Administration, as well as by other Government agencies, universities, industry, and research organizations both in the United States and abroad.* Subscription price: Domestic - $100.00 a year; Foreign - $125.00 a year. Single copy price: Domestic - $6.50 a copy; Foreign - $8.15 a copy. [STAR](File Code 2E) NAS 1.9/4: S/N 033-000-80004-5

Scientific Research With the Space Telescope. *Contains the proceedings of the International Astronomical Union Colloquium Number 54, cosponsored by COSPAR, and held at the Institute for Advanced Study, Princeton, New Jersey, August 8-11, 1979.* 1979. 327 p. il.
NAS 1.55:2111 S/N 033-000-00782-5 $ 9.00

Search for Extraterrestrial Intelligence, SETI. *Presents the findings of a series of workshops conducted by NASA's Ames Research Center on interstellar communication; extrasolar planetary detection; and the evolution of intelligent species and technological civilizations (cultural evolution).* 1977. 276 p. il.
NAS 1.21:419 S/N 033-000-00696-9 8.00

Shuttle Era. *Describes the Space Shuttle system, presents a mission profile, and explains why the Shuttle has ushered in a new era for America's space program.* Rev. 1981. 8 p. il.
NAS 1.20:NF-127/3-81
S/N 033-000-00822-8 2.00

Skylab and the Sun. 1973. 56 p. il.
NAS 1.19:119 S/N 033-000-00533-4 3.25

Skylab's Astronomy and Space Sciences. *Colorfully illustrated, this volume summarizes some of the experiments performed and results achieved onboard Skylab.* 1979. 122 p. il. Clothbound.
NAS 1.21:404 S/N 033-000-00767-1 13.00

Soviet Space Programs: 1976-1980, Part 1, Supporting Vehicles and Launch Vehicles, Political Goals and Purposes, International Cooperation in Space, Administration, Resource Burden, Future Outlook. 1982. 461 p. il. Y 4.C 73/7:Sp 1/2/pt.1
S/N 052-070-05800-5 7.50

Space Activities of the United States, Soviet Union, and Other Launching Countries, Organizations: 1957-1981, Report. 1982. 145 p.
Y 4.Sci 2:97/Y S/N 052-070-05738-6 5.00

Space Resources and Space Settlements. *Contains the technical papers from the 1977 Summer Study on Space Settlements and Industrialization Using Nonterrestrial Materials, held at NASA Ames Research Center.* 1979. 288 p. il. NAS 1.21:428 S/N 033-000-00765-5 9.00

Space Science Research in the United States, A Technical Memorandum. *Examines the direction and purpose of the United States space science program.* 1982. 58 p. il.
Y 3.T 22/2:2 Sp 1 S/N 052-003-00895-5 4.75

Space Settlements, A Design Study. *Presents a picture of how people might permanently sustain life in space on a large scale.* 1977. 185 p. il.
NAS 1.21:413 S/N 033-000-00669-1 $10.00

Space Shuttle. *The development of the space shuttle, its components, and a typical mission are all described in this interesting NASA factsheet. The realistic drawings illustrate how various shuttle missions will be carried out and an improved space suit and unique rescue system that have been developed for the shuttle are described.* 1977. 8 p. il.
NAS 1.20:NF-79 S/N 033-000-00679-9 2.00

Space Shuttle at Work. *Handsomely illustrated in color and black-and-white, this publication describes the lay-out of the Shuttle, its capabilities, the way it is launched and landed, a typical week's work for the crew, and the plans and dreams that weekly, routine space transportation permit.* 1979. 76 p. il.
NAS 1.19:156 S/N 033-000-00779-5 5.00

Spacelab: An International Short-Stay Orbiting Laboratory. *Traces the historical and technological developments of a joint program between NASA and the European Space Agency (ESA) leading to the building of the Space Shuttle Columbia's spacelab.* 1983. 82 p. il.
NAS 1.19:165 S/N 033-000-00895-3 7.00

Spinoff, 1984. *An illustrated annual review of the space program.* 1984. 126 p. il.
NAS 1.1/4:984 S/N 033-000-00920-8 4.75

Star Splitters: The High Energy Astronomy Observatories. *Traces the history and development of NASA's High Energy Astronomy Observatory (HEAO) Program.* 1984. 191 p. il.
Clothbound. NAS 1.21:466 S/N 033-000-00907-1 12.00

Telescopes and Space Explorattion. *This colorful booklet shows why progress in contemporary astronomy and astrophysics depends on complementary investigations with sensitive telescopes, some of which can be on the Earth's surface and others which must be in space.* 1976. 16 p. il.
NAS 1.2:T 23/2 S/N 033-000-00647-1 2.00

UNISPACE '82: A Context for International Cooperation and Competition, A Technical Memorandum. *As a post-conference review of UNISPACE '82 (United Nation's Conference on the Exploration and Peaceful Uses of Outer Space), this publication examines how the United States might make better use of international fora to achieve its diplomatic, commercial, and technical ends in space technology.* 1983. 93 p. il.
Y 3.T 22/2:11 Un 3 S/N 052-003-00903-0 5.50

United States and Soviet Progress in Space: Summary Data Through 1979 and a Forward Look, Report. 1980. 105 p. Y 4.Sci 2:96/LL S/N 052-070-05304-6 4.50

United States Civilian Space Programs. *The following volumes review what has been accomplished by the United States in space flight since the inception of the space program.*

Volume 1, 1958-1978, Report. 1981. 1381 p. il.
Y 4.Sci 2:97/D S/N 052-070-05579-1 $15.00

Volume 2, 1958-1981. 1983. 406 p. il.
Y 4.Sci 2:98/M/v.2 S/N 052-070-05867-6 6.00

Voyager at Neptune and Triton: 1989. *Describes the Voyager project and its voyage to Neptune in September of 1989, where it will encounter Triton, Neptune's largest moon.* 1984. 12 p. il.
NAS 1.12/7:400-230 S/N 033-000-00919-4 1.50

Watch Upon a Star. *Describes the mission and activities of the Space Environment Services Center, which is charged with monitoring the Sun for events which affect life on Earth, and discusses the major physical and behavioral characteristics of this, Earth's own star.* 1977. 18 p. il.
C 55.2:St 2 S/N 003-018-00082-2 2.00
